CHRONOMETER.

CHRONOMETER, from χρόνος, *temporis*, and μέτρον, *menſura*, is a term in *Horology*, which, in its comprehenſive ſignification, may mean any machine which *meaſures time*, of which there have been various kinds, ſuch as *Clepſydræ*, *clocks*, *watches*, *regulators*, and *time-keepers*, or *time-pieces*, but the application of this term has been more particularly confined by mechanicians to two kinds of machines; firſt to ſuch as meaſure very ſmall portions of time only, by ſubdividing the ſecond: and, ſecondly, to ſuch as continue to meaſure long periods, with great accuracy under all the variations of temperature that ariſe out of the changes of ſeaſon and climate.

The former of theſe two kinds of machines was originally conſtructed for philoſophical purpoſes, ſuch as meaſuring the time of the deſcent of a falling body through a given ſpace, of the efflux of a fluid out of a given aperture under certain circumſtances, of the paſſage of a heavenly body along the eye-piece of a teleſcope, of the velocity of ſound compared with that of light, &c.

The deſcription of a machine of this kind is given in Dr. Deſagulier's Experimental Philoſophy, and Dr. Hutton ſays he has ſeen one, that profeſſes to meaſure ſo ſmall a portion as the *fortieth* part of a ſecond, but that it cannot be ſtopped with certainty within the tenth part of the propoſed degree of accuracy. Mr. W. Nicholſon, however, ſays, (vol. iii. p. 50, in a note of his Philoſophical Journal, 4to ſeries.) "that there have been inſtruments made to divide the ſecond into a *hundred* parts; one of theſe, ſays he, made by Whitehurſt, and regulated by a fly, repeatedly meaſured the time of the fall of a leaden bullet, in ſome experiments which I ſaw, with no greater variation than *one-hundredth* part of the ſecond." The adoption of Mr. Atwood's machine has now ſuperſeded the uſe of ſuch a nice meaſure of time in the above experiment, and for all the other purpoſes, the *beat* of a watch, counted by the ear while the eye obſerves the object of experiment, ſeems to be not only the moſt convenient chronometer of any, but is ſufficiently accurate for any purpoſe when the beats are quick, and when their value is known. See our article BEATS, in *Horology*.

The ſecond kind of horological machines known by the appellation of chronometers, ſince Mr. Arnold the elder gave this name to his time-keepers, differs from an ordinary watch principally in the eſcapement and balance, and deſerves our more particular notice, inaſmuch as the act of navigating veſſels over the extenſive oceans of the univerſe, is greatly indebted to their accurate meaſurement of time, in all the variations of heat and cold, from the higheſt navigable latitudes to the equinoctial line. In ſteering a veſſel over the trackleſs deep, the great deſideratum is, to know at any given inſtant the relative longitude, or diſtance from the firſt meridian, and the latitude, or diſtance from the equinoctial line; a knowledge of theſe two guides will always ſuffice to direct on what point of the compaſs, where the variation is known, a veſſel is to be ſteered, if no current interfere, in order to gain a given harbour. The latter of theſe two guides, viz. the preſent latitude, can always be obtained, independently of the ſhip's reckoning by the log line, by an obſervation of any of the heavenly bodies when at its greateſt altitude, or even with ſufficient accuracy by two ſucceſſive altitudes taken at a diſtance from the meridian, provided the intermediate lapſe of time be accurately noted. The other requiſite, the preſent longitude, however, is not ſo readily obtained, the lunar method requiring tedious calculations not generally underſtood, and the occultations of the ſtars by the moon, and eclipſes of the ſun, moon, and Jupiter's ſatellites, not occurring with ſufficient frequency to be of much benefit, even if they could be obſerved with ac-

Strahan and Preſton,

curacy and convenience on board a ship. The method by a good chronometer is, however, not only simple in its application, but at all times readily attainable, and therefore is coming into general use. We will premise a few observations respecting the utility of a chronometer at sea, and the improvements it has successively experienced, before we proceed to describe the machine itself according to some of its more perfect constructions.

The earth, it is now generally believed, revolves on its axis, in every part of its annual orbit, in an uniform and equable manner, and, on this account, the period of its rotation has been fixed upon as the most proper standard of our measure of time, and, indeed, is the only invariable standard with which we are acquainted: this period, according to our mode of reckoning, is divided into 24 equal parts, as the rotation has a reference to the sun; and each of those 24 parts is called an hour, or a *solar* hour sometimes, by way of distinction from the *sidereal* hour, which is a 24th part of a rotation, as it regards a fixed star; hence an hour, or solar hour, means one 24th part of the time elapsed since any spot on the globe passed the sun on the meridian, or south point, in regard to that spot: two hours mean twice that space of time; and 24 hours the whole time of a solar rotation, which is longer than a sidereal rotation by 3^m 55^s 54^{th} of solar time, by reason of the sun having advanced apparently $59' 8'' 10'''$ in the ecliptic during a rotation; so that a solar, being only a relative rotation, is more than a sidereal or absolute rotation, by as much as, taken collectively, amounts to an entire rotation in each annual revolution of the earth, to which cause the apparent motion of the sun in the ecliptic is owing: and, to this cause, is to be attributed the reason why there is a sidereal more than a solar day in each year. But the period of a solar rotation of the earth, or any portion of it, may be, and frequently is, reckoned in other terms, implying space passed through in a rotation, instead of the time occupied by the motion through that space: mathematicians have long been in the habit of dividing a circle into 360 equal parts, one of which is called a degree, or $1°$; and, as an equatorial section of the earth would be a circle, geographers and astronomers have supposed the equinoctial line divided into $360°$, and each degree divided into $60'$, (60 minutes) or geographical miles, which minutes are again subdivided into $60''$ (60 seconds), as we divide an hour into 60^m, and each of those again into 60^s: hence, as the whole $360°$ of the earth's circumference pass the sun's meridian ray in 24^h, we know that $15°$ must pass the same in one hour, or $1°$ in four minutes of time, as also $1'$ in 4^s; consequently, when we know the time that has elapsed since any given spot on the globe has passed the meridian sun, we know also, by allowing $1°$ to 4^m of time, how many degrees of the equinoctial have passed in the same time; hours, with their divisions and subdivisions, and degrees, with their divisions and subdivisions, being mutually convertible one into the other by direct proportion, or more readily by tables constructed on purpose. It is necessary, however, that we should notice, that there is a difference between a *real* and an *apparent* rotation of the earth as it relates to the sun, partly by reason of the earth's axis being inclined in an angle of nearly $23\frac{1}{2}°$ to its annual orbit, causing thereby a necessary reduction of apparent motion in the ecliptic, or earth's path, to real equable motion in the equator, and partly by the alternate acceleration and retardation of the earth's motion in her orbit at different times of the year, which irregularity requires a correction called the "Equation of the Center:" these two causes of apparent irregularity in the earth's rotations have their joint effects allowed for, by what is called "Equation of Time," usually inserted in a table with this title, and also placed in the column of "clock fast," or "clock slow," in the almanacs; the quantity, therefore, corresponding to any given day in the year, in the equation table or almanac, must always be added to or subtracted from the time shown by an accurate chronometer, to make it agree with *apparent*, or what the French (and lately some of our English authors) improperly call *true* time; that time in our opinion being *true*, which is mean, and which corresponds to the real rotations of the earth; for these rotations, considered by themselves, are equable, and not affected by the causes of those two *apparent* irregularities we have noticed, as arising solely out of the relative positions and situations of the earth and sun.

But we have not to regard only the period of the earth's solar rotation; its direction, also, must be considered, which is from that point of the horizon, which we call west, to that which is denominated east; thereby causing the sun, which is really a stationary body, or nearly so, to *appear* to move on the contrary from east to west every solar day, and the stars likewise, in the same direction, once in every sidereal day; but these latter bodies, being placed at an immense distance beyond the earth's orbit, have no apparent change of place, and, therefore, require no correction; consequently, there is no difference at any part of the year between a *mean* or *true*, and an *apparent*, sidereal day, which must have been the case, notwithstanding the immense distance of the stars, if the rotations of the earth had not been uniformly equable. It is on account of this equality among the sidereal days that astronomers have proportioned the pendulums of their regulators to vibrate sidereal seconds, that the right ascension of the heavenly bodies is given in sidereal time, and that the late Margetts made his chronometers, with great ingenuity, to show at the same time both solar and sidereal time, and, consequently, the sun's mean right ascension at any time, which is always equal to their difference: and we may add here, that the constant variation that is taking place between mean and apparent solar time, was the reason why a clockmaker in London, whose name is unknown, and after him on the continent, H. Sully, Alexander le Bon, Julien le Roy, Enderlin, l'Admiraud Passemant, Rivaz, Berthoud, and others, have made equation clocks on different constructions, to indicate both mean and equated, or apparent time.

From these introductory remarks on time, and its connection with, or rather dependence on, the earth's rotation on its axis, it is easy to conceive, that all places on the globe which pass the sun's meridian ray soonest, count their 12 o'clock, or noon, earlier than those which follow in succession; but the eastern parts pass first, and thence have their time more advanced, or earlier than the following more western parts have; and the difference is, as we have said, at the rate of 4^m for every degree of distance. This distance is called *longitude*, by reason of the equatorial diameter of the earth being *longer* than the polar diameter, in the direction of which latter, the breadth or *latitude* of the earth is counted both ways from the middle. The longitude may have its reckoning to commence at any assignable point on the globe, and all the other parts will be called east or west of that point, which is called the first meridian, accordingly as they precede or follow it in each rotation of the earth, and the quantity will be either so many hours, minutes, and seconds of time, or so many degrees, minutes, and seconds of space, as correspond to that time. Now, it is very obvious, that, if we could at the same instant know the time accurately, as counted at each of two different places, situated respectively east and west of one another, the difference of of thofe two times fo indicated, would be their difference of longitude in time, which, converted into degrees, minutes, and feconds, would be their difference of longitude in this denomination, from which, in a known latitude, the actual diftance of the two refpective places may, by calculation, be afcertained. What, therefore, a chronometer has to do, is, *to tell at all times the hour, minute, and fecond, as counted at the firft meridian*, whether London, Paris, or any other place, to the time of which it was accurately put previoufly to the commencement of a voyage; for, as the time at any ifland, or place of a fhip, can be had by means of Hadley's quadrant, or fextant, or more accurately by means of Troughton's reflecting circle, from a celeftial obfervation; the quantity that this time exceeds or falls fhort of the time indicated by the machine, as being the time at that moment at the firft meridian, will be the ifland's or fhip's comparative longitude in time, eaft, if the chronometer is behind, but weft, if before the time by a celeftial obfervation. In our Englifh fhips, the chronometer is a kind of travelling companion which tells, whenever confulted, what the exact time is at Greenwich; nor is it indifpenfably neceffary that it fhould keep time exactly with the clock at Greenwich obfervatory, provided the daily gain or lofs, called the *rate*, be afcertained and applied as a correction accordingly as it accumulates. It is, however, an indifpenfable requifite, that the daily gain or lofs fhould not differ materially from itfelf at different periods, or under the changes of temperature experienced in different climates; and the fulfilment of this condition conftitutes any portable horological machine, a marine *chronometer*, or time-keeper, whatever may be its conftruction or price. Any of the other methods of afcertaining the longitude may be occafionally put in practice with advantage, as a check upon the fimple determination by the chronometer; for their operations will detect its daily errors, and afcertain nearly their amount at the time.

The firft perfon who propofed to afcertain the relative longitude of any place or fhip at fea, by means of an horological machine for indicating the time of the firft meridian, was, as has been afferted, Gemma Frifius, about the year 1530; (vide "De Principiis Aftronomiæ et Cofmographiæ.") This method was defcribed and recommended in Carpenter's Geography fo early as the year 1635; but the ftate in which horological machines was, at that time, prevented his accomplifhing the defign: the idea, however, once fuggefted, was valuable; and ftimulated ingenious mechanifts, in times fucceeding, to attempt the accomplifhment of an object of fuch national importance. The difcovery of the ifochronifm of the pendulum turned the minds of ingenious men to the improvement of clocks; and we find that lord Kincardine tried a marine pendulum clock by Dr. Hooke in the year 1662; and that Chriftian Huygens, the celebrated Dutch mathematician and mechanician, contrived a time-keeper, actuated by a fpring, and regulated by a pendulum, which was tried at fea by major Holmes in the year 1664, and fpoken of by him in favourable terms. The efcapement was of the crown-wheel kind, which, from its nature, is almoft conftantly under the influence of the maintaining power; but a fmall weight connected with the crown-wheel, was raifed every half-fecond by the maintaining power, and gave an impulfe to the pendulum, which, therefore, was not affected by the irregular tranfmiffion of the maintaining power through the train of wheel-work: this contrivance was ingenious, and obtained the name of *remontoir*. The pendulum, however, was not only unfteady in its action during the toffing of a fhip, but was fubject to a variation in its length by change of temperature, as well as to a change of weight depending on the parallel of latitude; the latter of which changes, indeed, was afterwards difcovered. There was, moreover, a pair of cycloidal cheeks of brafs fo fixed, as that the thread of fufpenfion, by being evolved from them alternately at each fucceffive vibration, might make the bob of the pendulum defcribe the involute of a cycloid, which this author firft proved, was itfelf a cycloid, poffeffed of the peculiar property of rendering the vibrations in long and fhort arcs of equal duration; this cycloidal doctrine was plaufible in theory, but could not be reduced to practice, becaufe it fuppofed; 1ft, the pendulum invariable in length; 2dly, the collection of all the weight to be into one point; and 3dly, the abfence of friction and other kinds of refiftance, to which mechanifm is fubject. Huygens's contrivances, notwithftanding, together with the doctrines contained in his "Horologium Ofcillatorium," may be confidered as having laid the foundation of horological fcience.

The balance, which had preceded the pendulum, was again reforted to as a regulator of portable time-keepers; and though it was found incompetent to its office in a detached ftate, yet, by the aid of a flender fpring to quicken and regulate its fluggifh vibrations, it has ultimately turned out to be of eminent utility. It has been contefted by Huygens and Dr. Hooke, which of thefe two fkilful mechanicians firft introduced the fpring, called ufually the pendulum fpring, from the ifochronal property which it poffeffes, like the pendulum, when of a proper ftrength, fhape, and length; and F. Berthoud afferts, that though Hooke applied it firft in a ftraight form, yet Huygens firft adopted the fpiral fhape, as being more favourable to ifochronifm; while others are of opinion, with more probability, that Hooke actually applied it in a fpiral form among the *twenty* feveral methods that he faid, in his lectures at Grefham college, in the year 1664, might be ufed to anfwer the fame purpofe (vide "Lectiones Cutlerianæ," 1673.) Indeed the account of the fpiral fpring, adopted by Huygens, was not publifhed in the Philofophical Tranfactions, until the year 1675, N° 112, whereas Hooke had difcovered the ifochronifm of fprings, and regiftered his difcovery by an anagram compofed of the Latin fentence "Ut tenfio fic vis," in the year 1658.

But whoever was the inventor of the fpiral form of the fpring attached to the balance, and making with it a regulator for portable machines, they both ftill remained fubject to alterations in their dimenfions by the fucceffive changes of heat and cold; for, by the former of thefe oppofite temperatures, the fpring became weaker, and the fize and confequent momentum of the balance greater, in confequence of their enlargement, fo as to produce a very fenfible lofs in the daily rate of going of a watch with fuch a regulator; alfo an acceleration beyond a mean rate was foon obferved to be the confequence of increafed cold, which, on the contrary, diminifhed the dimenfions of the metallic parts, and thereby, at the fame time gave additional ftrength to the fpring, and likewife reduced the fize and momentum of the balance. About the fame period Leibnitz attempted to confine the vibrations of the balance with a fpiral fpring, to be of equal extent, by means of an additional fpring to be applied to the balance wheel, and to be, like Huygens' remontoir, wound up by the maintaining power; but his endeavours, whatever ideas they may have fuggefted to Harrifon, Mudge, or Haley, for their auxiliary fprings, were not crowned with complete fuccefs. Hautefeuille alfo, in the year 1674, prefented to the Academy of Sciences, at Paris, a balance with a ftraight fpring, acting fomehow inftead of an efcapement, but how far it refembled the fpring detent of Arnold we know not, nor do we find that it was adopted in practice. This fociety, notwithftanding, thought the fubject of fuch importance, that, in the year 1720, they proposed the following question to be determined for a public reward: viz. "What is the most perfect method of preserving on the sea the equable motion of a pendulum, either by the construction of the machine, or by the suspension?" A memoir written by Massy, a Dutch clock-maker, obtained the prize, but he had not the satisfaction of seeing his plan executed. About a year afterwards (1724) Henry Sully, an English clock-maker, who had settled at Paris about eight years previously, presented the same academy with a marine time-keeper, made in 1721, and published a description of it in French, by the title of "Description abrégée d'une horloge de nouvelle invention pour la juste mesure du temps en mer." Besides the above, Sully made a second marine time-keeper, which was tried at sea in 1726, but the inventor died two years afterwards, a martyr to his horological studies, before he had brought his machines to that state of perfection which their object demanded. His pieces had vertical balances carrying cycloidal metallic pieces, round which a thread, or slender wire, was wound at the upper end, while the lower end was attached to a lever with an adjustable weight to effect the isochronism of the balance, instead of a spiral spring: the horizontal pivots of the balance also moved on the angular point included between two large rollers, which method of lessening friction, we believe, was the invention of this author. He also made a marine watch with a spiral pendulum spring, into which friction rollers, like Mudge's, were introduced, and had he lived longer, chronometry would no doubt have been greatly promoted by his labours.

It was about this period, that jewelling, another essential improvement in time-pieces, was introduced, according to Berthoud, by Mr. Fatio, a native of Geneva, who, not meeting with encouragement in France, came over into England, and brought his invention into notice.

The Academy of Sciences at Paris again proposed a reward for the year 1747: the subject was "The best method of finding the hour at sea, whether by day, by twilight, or at night, when the horizon cannot be distinguished." The reward was obtained by Daniel Bernouilly's memoir, intitled, "Recherches mechaniques, et astronomiques," in which was displayed much science, but the author's want of skill in mechanical operations prevented his labours being attended with complete success.

In the mean time, the changes in the length of the pendulum began to be compensated, first by means of quicksilver contained in a tubular rod, by Graham, and soon after by the opposite expansions of different metals, by Harrison, who, stimulated by the British parliamentary reward that had been previously offered to the public for marine time-keepers, applied the same principle to a watch to effect a self-regulating kirb (or curb), for limiting the effective length of the spiral pendulum-spring to correspond to the successive changes of heat and cold, which changes were now known to alter the force of this spring, and the momentum of the balance. From this origin we may date the beginning of all the different kinds of compensation-mechanism that have proved permanently useful in time-keeping; and if we add to Harrison's invention of the metallic compensation, his remontoir, and his addition of a secondary spring as an equivalent substitute for the maintaining power during the time of winding up, which is an essential requisite in producing permanent motion, he may be fairly considered as the parent of modern chronometry.

The British parliament had, indeed, before the French academy, offered, so early as the year 1714, in the reign of queen Anne, a reward of 10,000l. for any method of determining the longitude within the accuracy of one degree of a great circle; of 15,000l. within the limit of 40 geographical miles, and of 20,000l. within the limit of 30 such miles, or half of a degree, provided such method should extend more than 80 miles from the coast: and after this act, two others passed in the reign of George II. stat. 14 and 26, to promote the same purpose; but an act passed in the present reign, in the year 1774, repealing all the former ones, and offering separate rewards to any person who should invent a practical method of determining, within certain circumscribed limits, the longitude of a ship at sea: for a time-keeper, the reward held forth to the public is, 5000l. for determining the longitude to or within one degree; 7500l. for determining the same to 40 geographical miles, and 10,000l. for a determination at or within half of a degree. This act, notwithstanding its abridged limits and diminished rewards, has produced several candidates since Harrison, who received the whole reward of the first act, for parliamentary remuneration, of whom Mudge, the two Arnolds, and Earnshaw, have had their labours, as will be seen hereafter, crowned with partial success. Besides these, there have been various other chronometer-makers, whose pieces have performed with great accuracy, but whose names we omit to introduce here, lest we should seem partial to some at the expence of the reputation of others. Indeed, the art of constructing chronometers is lately become so general, that it is difficult to decide whose name ought to stand first on the list of excellent makers, and we hope that the spirit of competition for public fame will continue to entitle our English manufacturers to that preference among naval officers, which the excellence of their workmanship entitles them to expect. For, even in a commercial point of view, it was proved to the late Mr. Pitt, when he laid a tax on watches, by the committee of watch-makers convened in the parish of Clerkenwell, that a piece of the value of 500l. had been manufactured out of materials which did not, in their native original state, cost more than *sixpence!* This representation, we are credibly informed, induced the noble statesman to abandon his plan of taxing an article, the value of which depended so much upon ingenuity and labour, and by the manufacture of which thousands of subjects are entirely supported: nay, further, on learning that the French and Swiss could afford to sell three gold watches for the price of one English one, the same minister took off the duty of sixteen shillings per oz. from watch-cases of this metal, and substituted only one shilling, the price of the trial at Goldsmiths'-hall. We have just said that Harrison obtained the first and most ample reward for his inventions, but we are not to conclude from thence, that his pieces excelled all others; they were specimens of great ingenuity and proofs of unwearied industry, which certainly were not overpaid; but the inventor himself was candid enough to confess that the balance, balance-spring, and compensation-curb, were not contemporaneously affected by heat and cold, but that small pieces of metal were sooner affected than large ones, and also pieces in motion before pieces at rest; whence he was led to conclude, that if the provision for heat and cold could properly be in the balance itself, as was the case with his gridiron pendulum in clocks, the time-piece might be made much more perfect.

Harrison's suggestion of a compensation-balance, in place of a compensating curb for the balance-spring, found its way into France, and roused the attention of the watch-makers of that nation; and, to do them justice, we must allow that Peter, the eldest son of Julien le Roy, who was himself an eminent watch-maker, had the honour to be the first who accomplished the suggested desideratum, by means

of

of two thermometers, one of mercury, and the other of alcohol, attached to and carried by the balance itſelf, which contrivance effected the compenſation, by bringing a portion of the mercury nearer to, or by removing it farther from the centre of the balance, according to the different ſtates of the atmoſphere. (See the Deſcriptiou under COMPENSATION-*balance*.) A chronometer on this conſtruction was preſented by Peter le Roy to the king of France, on Aug. 5th, 1766, for which the prize of the Academy of Sciences was awarded him on the laſt day of the ſame month: he alſo publiſhed an account to accompany the piece, entitled, "Memoire ſur la meillure manière de meſurer le temps en mer, &c." in which memoir he aſſerts, a circumſtance very worthy of notice, that he made another compenſation-balance entirely of pieces of different metals; viz. of braſs and ſteel riveted together, like Harriſon's compenſation-curb, but bent into two ſeparate ſemi-circles in ſuch a way, that each, carrying a metallic weight near its extremity, brought it alternately nearer to, or removed it farther from the centre of the balance thus formed, agreeably to the variations of the atmoſpheric temperature; and though the inventor preferred at the time the thermometrical compenſation, yet the metallic one, ſpoken of in the memoir in queſtion, was, no doubt, the archetype of all our preſent compenſation-balances. It might now have been expected that a time-piece, with a movement aided by friction-rollers, or by jewels in the pivot-holes, and with a compenſation-balance regulated by a ſpiral-ſpring, would have performed alike under all circumſtances, but ſtill it was found that, however well the fuſee was ſhapen, and adjuſted to the different intenſities of the main-ſpring, yet ſuch an unequal tranſmiſſion of that power took place, even in the beſt movements, in conſequence of there being alternately favourable and unfavourable poſitions of the acting teeth of the wheels and pinions, and in conſequence of the impediments to free motion occaſioned by the variable denſity of the oil uſed, and by the acceſſion of particles of extraneous matter, that the action of the pallet-wheel upon the pallets then in uſe was found ſufficiently irregular to occaſion an inequality in the impulſes given to the balance, and a conſequent inequality in the magnitude of the arcs of vibration. This inequality in the magnitude of the arcs of vibration would not, indeed, have affected the rate of the going of the chronometer, if all lengths of the regulating-ſpring had been found on trial to be equally iſochronal, but the ſame Peter le Roy diſcovered what Dr. Hooke knew long before, (vide his Poſtſcript to "a Deſcription of Helioſcopes, &c.") that there is a *certain length* in each good uniform ſpring *which only* is iſochronal, or, in other words, which has the property of regulating the balance ſo, that all arcs of vibration, long or ſhort, ſhall be performed in the ſame time. This diſcovery, or rather re-diſcovery, of Peter le Roy, at a time when chronometry had made conſiderable advances towards perfection, was calculated to do away the ſanguine hopes that had been entertained of the good performance of time-pieces on Harriſon's conſtruction, in which the effective length of the regulating-ſpring was conſtantly altering with the variations of temperature; and to this circumſtance principally may be imputed, perhaps, the ſmall number of time-pieces that were manufactured after Harriſon's model, notwithſtanding the large premium which was awarded him. A remedy for the unequal tranſmiſſion of the maintaining power had been, however, adopted by Harriſon, when he introduced the remontoir to produce equable action at the contrate-wheel of his pieces, a contrivance worthy of his genius, whether the idea was original, or borrowed by him from Huygens; but this was a remedy for only one of the two cauſes of irregularity in the momentum of his balance; it might, and probably did, equalize the maintaining power nearly, but would not counteract the iſochronal defect produced in the regulating-ſpring by the compenſation-curb, in all the various arcs of vibration which every piece is liable to experience in their different ſtates of foulneſs.

The obſtacles to equal tranſmiſſion of force in a chronometer, led to the invention of various eſcapements, both on the continent and in England; ſome of which were intended to act iſochronally in concert with the regulating ſpring, and others were ſo conſtructed as to give the impulſe almoſt inſtantaneouſly, and at the moſt favourable inſtant of the vibration of the balance, ſo that the force derived from the maintaining power, to perpetuate the vibrations, might derange the natural iſochronal property of the balance, and its regulating ſpring as little as poſſible.

On conſidering this ſubject, it occurred to the moſt ſcientific artiſts, that the regulating power of the balance and balance-ſpring, which was found to be too much under the dominion of the maintaining power with the common eſcapements, would be the leaſt deranged if the impulſe derived from the maintaining power were momentary, particularly if it were applied at that point of the vibration where the momentum of the balance is a maximum; it alſo occurred, that the momentum of the balance itſelf ought to be as great as practicable, compared with the impulſe given to the pallet-wheel, and likewiſe that a momentum compoſed more of velocity than of weight would be moſt favourable for a balance with ſlender pivots. Theſe, and ſimilar conſiderations, the reſult of much thought and reaſoning, ſuggeſted a great variety of deſigns for new eſcapements, many of which have been brought into practice with an advantage correſponding to the importance of the object; the moſt recent of which promiſes to be of permanent utility in chronometry. Theſe eſcapements have obtained the appellation of *free* or *detached*, from the circumſtance of their being detached from the balance during the greateſt part of its vibration. It has been matter of contention among horological writers, who was really the firſt inventor of a detached eſcapement, but it ſeems now to be pretty generally admitted, that Peter le Roy, whom we have mentioned as the inventor of the firſt compenſation balance, was alſo the inventor of the firſt detached eſcapement. It would lead us far beyond the limits of our preſent article minutely to deſcribe here all the variations in the ſhape and mode of action of the different eſcapements, by Julien and Peter le Roy, Berthoud, and others, that have been made on the continent, as well as of thoſe made in Britain; on which account we ſhall reſume the ſubject under the article ESCAPEMENT, and there give a detailed account of the ſucceſſive eſcapements, as nearly in their order of time as can be aſcertained. In the mean time, the reader will obtain, we preſume, a ſufficient knowledge of the eſcapements at preſent in uſe, from the deſcriptions that are ſubjoined to this article, of ſome of the beſt chronometers of modern makers, where we have given drawings and an account of an entire piece by Brockbank, and of ſuch parts of the pieces of other modern makers as differ from it in conſtruction. We wiſh it, however, to be diſtinctly underſtood, that we diſclaim all partiality to individuals, and give a drawing of Brockbank's chronometer in an entire ſtate, for no other reaſon but becauſe we are unwilling to diminiſh the ſale of the pamphlet containing the drawings and deſcriptions of thoſe by Arnold and Earnſhaw, lately publiſhed by order of the commiſſioners of longitude; and alſo becauſe Meſſrs. J. Brockbank and Co. have been ſo obliging as to allow us to take ſuch original drawings as it is preſumed will ſhew the relative ſituations of the different parts in a favourable point

of

of view, for giving a clear idea of their relative offices and modes of action.

A method having been deviſed of limiting the quantity of impulſe given to the balance, ſo as to be juſt ſufficient to keep it vibrating when put in motion, but not ſufficient to produce motion from a ſtate of quieſcence, as will be ſeen hereafter, and a ſelf-compenſating mechaniſm having been adapted to the balance itſelf, it may now be fairly inferred, that chronometers have arrived nearly at their *ne plus ultra* of perfection, and that they may ſhortly be expected to find the permanent level of their price, uninfluenced by the recommendation of a ſuppoſed ſuperiority ariſing out of the *name* of the *maker*, or rather, as we might ſay, of the *vender;* for it is a fact not to be controverted, that more chronometers have been ſold by one individual than have been or could be made in the ſame time under his own roof. Still, how[illegible]*uſtment* of a chronometer for rate, temperature, heat, and poſition, is an object of the utmoſt importance to the due performance of even the beſt machine of this kind that ever was made; and if improvements are yet neceſſary in this delicate but important branch of our manufactures, they are ſuch as ought, and may reaſonably be expected, to conduce to accuracy and expedition in completing thoſe four kinds of operations; operations which have been found to be very troubleſome in ſome of the conſtructions, inaſmuch as one of the adjuſtments, however delicately made, may not only be over or under-done, but may and frequently does derange another adjuſtment previouſly made. Indeed, in the preſent advanced ſtate of chronometry, one maker's excellence is often diſtinguiſhed from that of another by ſome ſlight deviation from his contemporaries' method of ſhaping certain parts, or of adjuſting the balance according to ſome ſecret method peculiar to himſelf, which he does not chooſe to diſcloſe, and for which, perhaps, he cannot give a good reaſon; hence, an important trifle, no way dependent on or connected with ſcientific principles, has been found, in certain inſtances, to lay the foundation for pretenſions to excluſive merit.

We will conclude our narrative of the improvements in chronometry, by pointing out briefly ſome of the diſtinguiſhing features of the different conſtructions of our contemporaries; and leave to the public the exerciſe of their own choice in the ſelection of a particular maker. Without entering more minutely into a detail of the French chronometers in this place, it may be ſufficient to ſtate here generally, that their detached eſcapements have detents, or pieces to ſuſpend the maintaining power for a certain time, moveable on an arbor with pivots, as will be ſeen under the article Escapement; whereas the Engliſh detents act by means of ſprings without pivots, which conſequently require no oil, and are alſo of a more ſimple conſtruction.

The late Mr. Arnold took out two patents for improvements in his chronometers, the one in April 1776, and the other in 1782. The former of theſe patents was for the invention and application of compenſation bars in the conſtruction of his balance, together with the invention and application of what he calls the helical, but which is properly the cylindrical balance-ſpring. The ſecond patent was for three different ways of applying the compenſation-bars, for an improvement in the balance-ſpring, particularly in the bending of the laſt coil at the end of it, for his invention and application of the ſpring-detent, and alſo for the cycloidal, or more properly epicycloidal ſhape of the tooth of the balance-wheel. It has been already ſaid, that Peter le Roy was the firſt who applied a metallic compenſation to the balance itſelf, but it does not neceſſarily follow from thence, that Arnold did not alſo invent the one he adopted. We are perſuaded that a man of Mr. Arnold's known integrity and veracity would not make oath, in taking out a patent, of an invention which he did not at leaſt conſider as his own; and we ſhall have occaſion to ſhew, under our article Compensation-*balance*, a variety of different ſhapes given by Arnold to his balances, and actually tried in practice *before* he adopted the one in preſent uſe; ſome of which balances are yet in exiſtence. At all events, Mr. Arnold muſt be allowed the merit of having introduced the compenſation-balance into general uſe, when Peter le Roy preferred the thermometrical tube. The late Mr. Brockbank was the firſt perſon who united the two metals by fuſion, which le Roy had united by pins, that muſt have interfered with the regularity of the flexure by different temperatures. Mr. Brockbank was alſo the firſt who uſed the method of turning an expanſion-rim out of a ſolid compound plate, made by covering the ſteel plate in a crucible of fuſed braſs, and of cutting it into portions afterwards, thereby enſuring the uniformity both of figure and weight, which two properties are equally eſſential in any balance, as the name imports; ſo that if it ſhould be contended that the conſtruction of the compenſation-balance was not invented in this country, at leaſt the practical application of the principle is our own; to which conſideration we may add, that Arnold ſenior invented and introduced the uſe of the ſpring detent, which requires no oil. Mr. Arnold was likewiſe the firſt watchmaker in England who laid much ſtreſs not only on the ſhape, but alſo on the particular length of the balance-ſpring in practice, which Dr. Hooke and Peter le Roy had both ſhewn was neceſſary to be attended to in order to render the ſpring iſochronal under all arcs of vibration, which is an eſſential object of adjuſtment, and which no doubt influenced his choice of the ſhape of the ſpring; and we are informed that he was ſo far ſucceſsful in his attempt to aſcertain the preciſe point for limiting the beſt practical length of ſome of his balance-ſprings, that, after the example of Peter le Roy, to whoſe contrivances, it muſt be confeſſed, he ſeems to have paid great deference, he ſucceeded in making a movement go accurately without a fuſee, by the mere regulation of an iſochronal ſpring, which is an indubitable proof that the irregularities of the maintaining power can have but little influence on the rate of a chronometer with an iſochronal balance-ſpring, eſpecially when it has, moreover, a detached eſcapement. Mr. Pennington affirms that there are many iſochronal points in every ſpring, which diſcovery accounts for the different lengths of the various balance-ſprings that are made of the ſame clue.

The late Mr. Mudge laboured to effect an equalization in the impulſe given to the balance by remontoirs of ſpiral ſprings, acting ſo conſtantly at each vibration, that the eſcapement of his time-keepers could not properly be called a detached one; though the one introduced into her majeſty's watch of his contrivance, and copied by the late Margetts, and by Emery, which gives an impulſe at every vibration, ſufficiently great to produce motion from a ſtate of reſt, may be claſſed among the detached kind.

Emery's balance had weights ſliding on its croſſes, and having their poſitions regulated under different degrees of heat by the variable flexure of compenſating bars compoſed of two different metals, in the ſhape of an S, as explained under our article Compensation *balance*, where it will appear that this was one of the varieties invented by Arnold, whoſe workman afterwards went to Emery. The Brockbanks have their chronometers diſtinguiſhed by the poſition of their locking and unlocking ſprings, and alſo by a peculiar method of banking by means of the protruſion of the coils of the balance-ſpring, as will be hereafter explained.

Earnſhaw's

Earnſhaw's chronometers differ from Arnold's in the ſhape and poſition of the detent and ſprings, in the ſhape of the balance wheel, and ſtructure of the balance ſpring and balance, all which will preſently be explained.

Recordon, ſucceſſor to *Emery*, at Charing Croſs, has a compenſation-balance perforated at the circumference with various tapped holes, into which the ſcrews of adjuſtment for temperature and poſition may be ſucceſſively removed, according to circumſtances: this mode of adjuſtment is practiſed by Pennington, and was, we underſtand, originally his contrivance.

Haley, a watch-maker at the corner of Wigmore-ſtreet, Cavendiſh-ſquare, took out a patent on the 17th of Auguſt, 1796, the particulars of which are given in the ſixth volume of the "Repertory of Arts." The principle on which the patent was granted, conſiſted chiefly of a ſecond cylindrical ſpring and ſpring-arbor with pallets, &c. interpoſed between the eſcapement-wheel and the balance to give an impulſe to the balance at each vibration, inſtead of the impulſe uſually given by the force tranſmitted through the train. See ESCAPEMENTS *for Watches*.

Grimalde, in the Strand, who now makes a conſiderable number of chronometers, ſome of which, we learn, have the teſtimony of naval officers in their favour, has informed us, that he places the cock ſo conveniently, and adjuſts for poſition ſo readily, by a particular contrivance, which does not require the cock to be taken off, that it would, we think, contribute to the ſtock of improvements already known, if he would make his method public.

Mr. *Hardy* has lately introduced a new mode of banking, by a lever attached to the exterior coil of an heliacal ſpring, which is thrown out to catch a pin in the balance; and has propoſed a new mode of making the ſpring iſochronal, by making the ſtud moveable on a ſecond ſpring; but experience muſt prove their utility.

We might add a long liſt of the other perſons who make chronometers, not in London only, but at Edinburgh and Liverpool, were we aware that there is any material difference in the conſtruction of their mechaniſm, or methods of adjuſtment, from thoſe, or ſome of thoſe, which we have noticed.

To aid the reſearches of thoſe readers who wiſh to trace more minutely the riſe and progreſs of the art of meaſuring time by mechanical inventions, we ſubjoin a liſt of the principal authors who have, from time to time, written on this intereſting ſubject, viz. Chronometer, or *Time-keeper*, by Harriſon. It was our intention to have given a perſpective drawing of one of Mr. James Harriſon's chronometers, or time-keepers, with a correſponding deſcription, but on an application by our draftſman to the aſtronomer royal to inſpect the interior parts of one of the machines, by the maker in queſtion, placed at the Obſervatory, he was informed that permiſſion to undo any of the covers or other parts of the mechaniſm could not be granted; we muſt therefore ſatisfy ourſelves with a verbal deſcription of the conſtruction, which, indeed, it is preſumed, will be deemed ſufficient, now that preferable conſtructions have been more recently adopted. We might, it is true, have copied the plans given in the ten plates of the pamphlet entitled the "Principles of Mr. Harriſon's Time-keeper," but ſome of them are ſo imperfectly explained, as to be unintelligible to any reader, except perhaps to ſuch as may have had occaſion to examine the original mechaniſm, and therefore would not be ſatisfactory to the public. The following particulars, relating to the dimenſions and other properties of the mechaniſm, apply more particularly to the *fourth* piece made by the inventor, and are extracted chiefly from the pamphlet juſt mentioned. The firſt obſervable diſtinction between Harriſon's train of wheel-work and that of an ordinary watch, is, that the numbers of his wheels and pinions are higher than had been uſual, as will appear from the ſubjoined arrangement, viz.

First or great wheel 96
Center pinion acting
with it - - - 21—120 ſecond wheel, which is concave
Its pinion 18—144 third wheel,
Its pinion 16—120 contrate wheel,
Bal. wheel pinion 12—15 bal. wheel,
2 pallets

If theſe numbers be examined according to our mode of *notation* under the article Clock-*Making*, the value of the train will be $\frac{120 \times 144 \times 120 \times 15 \times 2}{18 \times 16 \times 12} = 1800$ vibrations in an hour, or juſt five vibrations in each ſecond. The firſt or great wheel will revolve in $\frac{96}{21}$ of an hour, or make one revolution, along with the fuſee, in $4\frac{4}{7}$ hours, ſo that $5\frac{1}{4}$ turns or ſpirals on the fuſee will maintain a motion of 24 hours, $6\frac{1}{4}$ will actuate the works $28\frac{4}{7}$, and $6\frac{9}{16}$ juſt 30 hours.

The balance-wheel does not differ eſſentially from that in a common watch, but peculiar care is neceſſary in ſhaping the pallets, as will be ſeen more particularly under the article Escapement.

The bad effect produced in ordinary watches by an irregular tranſmiſſion of the maintaining power through the train, is here guarded againſt by the introduction of a ſlender ſpring, or remontoir, which is wound up eight times every minute by the maintaining power, or main-ſpring, and which actuates the contrate and balance-wheels, and conſequently impels the pallets with a conſtant impulſe, independently of the maintaining power, the latter being employed for no other purpoſe but for winding up the former as before ſpecified. This ſlender ſpring, which is ten inches long, though it weighs only $3\frac{1}{2}$ grains, is coiled in a ſpring barrel, apparently concentric with the contrate-wheel, and has its outer end attached to a hook in the barrel, with its inner end attached to another hook on the contrate-wheel. In order to make this delicate ſpring anſwer its purpoſe perpetually, two wheels, and as many pinions, in addition to the foregoing train, called the fourth and fifth wheel, and fourth and fifth pinion, are introduced in connection with a *fly*; as is likewiſe a detent with five arms, reſembling a ſtar, turning on the pivots of a common arbor. The action of theſe parts is not eaſily underſtood, even from a reference to the original drawings, much leſs from a verbal deſcription; but the intelligent reader will form a general idea from being told, that there are eight pins placed equidiſtantly on the plane of the contrate-wheel in a ſmall circle round the arbor; that one of the five arms of the detent acts with theſe ſucceſſively as the wheel itſelf revolves; that a ſecond arm carries a ſmall roller acting againſt a piece of braſs on the fifth wheel; that a third is bent at the end ſo as to catch a pin in the rim of the fifth wheel; and that the fourth and fifth arms are mere counterpoiſes to the other three, to preſerve an equilibrium. The numbers of theſe wheels and pinions appear to be as follow: of the fourth wheel 112, which ſtands concentrically over the contrate-wheel and ſpring-barrel, of its pinion 14, of the fifth wheel 104, and of its pinion 12; and it is to the arbor of this laſt pinion, we preſume, that the fly is attached, though it does not appear evident either from the drawings or deſcription, at leaſt to our apprehenſion. The mode of applying the three effective arms of the detent bears ſome reſemblance to the action of the detents in the ſtriking part of a clock, in which the count-wheel is uſed inſtead of a ſnail, and where the locking and unlocking are alternately effected at meaſured intervals of time. The detached eſcapements, however, have now rendered this complex mechaniſm ſuperfluous, and, indeed, it is manifeſt that the propoſed object, of having a completely detached power to act alike at all times on the pallets, is not thus perfectly effected; for the locking and unlocking eight times in every minute, to be produced by the ſlender ſpring in queſtion, muſt be ſuppoſed to interfere in a certain degree with its regularity of action on the pallets; and if it ſhould be contended, that the eight deductions from the force of the ſpring are regular and periodical in every minute, and that therefore they produce an equable effect, yet the ſame argument may be uſed in favour of a well made train, in which the irregularities in the tranſmiſſion of force from the main-ſpring may likewiſe be periodical, the wheels and pinions not being compoſed of *prime* numbers.

But it was not enough for Harriſon, that nearly an equable force was applied to maintain the motion of the balance, while the balance itſelf and alſo the balance ſpring were ſubject to alterations in their dimenſions by changes of temperature; he well knew that the ſpiral ſpring uſed in watches, had more power when contracted, and leſs when elongated, than a mean power, and alſo that an enlarged balance has a greater momentum than a diminiſhed one, and *vice verſâ*; the mode alſo of effecting an adjuſtment to counteract the conſequent loſs or gain in the rate of going, was well known not only to him, but to all watch-makers, and mechanically applied with ſucceſs, as at the preſent day, by a moveable ſtud to limit the effective length of the ſpring; but this adjuſtment was not a *ſelf-acting* one, an index was required to be moved by a manual operation, which index was connected with the moveable ſtud, and pointed out the quantity of the adjuſtment; it remained for Harriſon to deviſe a mode of action, entirely dependent on the ſtate of the atmoſphere at any moment, which of itſelf, would produce the requiſite adjuſtment; this he did, as we have already ſaid, by riveting together a ſlip of braſs and a ſlip of ſteel, which two metals are of unequal expanſibilities, to the remote end of which compound bar he attached his clip to hold the exterior thread of his ſpring, after the outer

outer end of it had passed through and been pinned to a stud of brass attached to the upper plate of the frame; the consequence proved, what none but a real genius would have foreseen, that the brass elongating and contracting alternately in opposite temperatures more than the steel, produced a curvature in the compound piece, the concave side of which was always occupied by the metal least elongated, that is, by the steel in hot, and by the brass in cold weather; hence the compound piece, which carried the stud backwards and forwards, was called a *kirb*, a Lincolnshire word for *curb*, which contrivance is destined to curb or command the effective length of the regulating spring. The only material objection that experience has pointed out against this self-compensating mechanism, is, as we have before observed, that small pieces of metal and pieces in motion do not alter their temperature at the same time with large pieces and pieces in motion; nor yet steel so soon as brass, even in similar circumstances; which consideration constitutes an objection to the use of the thermometrical curb; an objection first raised by Harrison himself, when it was greatly his interest to have suppressed such a suggestion, as he was a candidate for the parliamentary reward. Vide COMPENSATION-*balance*.

Harrison had besides remarked that in an ordinary watch the power which the main spring has over the balance, through the medium of the train, compared with the power that the regulating spring has over the same, is as *one* to *three* generally; this power from the main spring, he observed, being sufficient to put the watch in motion from a state of quiescence, must be too imperious for the balance, small and light as it was, to control it; accordingly he proposed, reasoning thus *a priori*, to give an additional momentum to his balance, compared with his maintaining power: but momentum was to be attained in three different ways, namely, by additional weight given to a balance of the usual diameter, by enlarging the diameter without increasing the weight, or lastly, by increasing both in a certain degree: the first mode was objectionable on account of the friction likely to be produced on the balance-pivots by a heavy balance; the second was also objectionable on account of the resistance of the air it was likely to experience; and therefore he fixed upon the last mode of gaining momentum, by partly enlarging the diameter, and partly increasing the weight of the balance in use; by which means he constructed a balance over which the force from the maintaining power of the remontoir has not more than *one-eightieth* part of the dominion that the balance-spring has. Hence in the time-keeper there is not force enough in the maintaining power to excite motion from a quiescent state, though there is power enough to overcome all the obstacles to continued motion, and to keep the piece going, when put in motion.

The balance of the time-keeper before us is described to be of more than three times the weight of that of a large ordinary watch, and of three times its diameter; for, according to the notes taken by Dr. Maskelyne, at the time of its examination, its diameter was $2\frac{1}{4}$ inches, and that of the plate $3\frac{8}{10}$; hence a point in its circumference will pass through 24 inches, or about four times the space of an ordinary watch, in each second, as Harrison calculates from the arc of its vibration; an advantage which has not been lost sight of by some of the modern makers of chronometers; and it may be considered as an axiom in chronometry, that the perfection of a balance, considered simply as a regulator, independently of its compensation-mechanism, consists in its having the greatest possible quantum of momentum with the least force from the train, and smallest quantity of friction and resistance from the air.

Notwithstanding, however, the above-mentioned contrivances in the construction of the balance, others were still wanting. Harrison inferred that large arcs were described in less time than small ones, from the circumstance of the piece going slower in a vertical position than in a horizontal one, where the vibrations were observed to be visibly longer, before any correction was applied; he therefore wanted, moreover, a compensation for the errors of position. The time-piece, he observed, did not go alike when in a vertical position, the hours III, VI, IX, and XIII, were successively uppermost, which defect he remedied by making the relative weights or dimensions different, at different sides of the balance, thereby equalizing the arcs of vibration in each vertical position. Again, to render the time of an horizontal vibration equal to that of a vertical one, he introduced a contrivance which he calls a cycloid-pin, which, when in contact with the regulating spring, quickens its vibrations; but as the longest vibrations seemed to require such secondary assistance the least, in those the spring left the pin for a longer time than in the smaller arcs of vibration, and therefore they were less affected by it. This cycloid-pin is very imperfectly described in the account of the plates, and, it appears, was added to the piece sent on trial to Jamaica, after its return; and it appears by no means certain, that any good end was obtained by its adoption. The idea of using adjustments for position, however, has proved of permanent utility. It may be necessary to add here, what will appear extraordinary, that there was no adjustment for mean time in Harrison's time-keeper, the compensation curb having usurped its place; but he professed to be able in general to ascertain its comparative rate of going by his regulator, or gridiron pendulum clock, near enough in three hours; and to apply the daily error in seconds to the time indicated, plus or minus, as the case might be; of course a longer trial was necessary for a very nice rate, before a voyage was commenced. Still it was necessary in a machine professing to measure the constant lapse of time perfectly, that it should not cease to go while the main-spring was in the act of being wound up; here was another field for our artisan's ingenuity; but with a great genius, as with a great warrior, or statesman, difficulties thrown in the way only tend to call forth the resources of an active and inventive mind; the auxiliary spring was the result of our inventor's sagacity, and the fusee itself, which before had been shapen to equalize the varying force of the main spring in its different states of tension, was now made to contain moreover within it a second spring, so bent in a contrary direction, that the force exerted by the first or main-spring wound it up to a resisting force exactly equal to the power necessary to be exerted on the train, before this power began to be transmitted further along the train. The contrivance will not be easily understood by a verbal description, except by men conversant in watch-work; it is thus; a concave ratchet with 55 teeth, is fixed to the inside of the large end of the fusee, the concavity of which is sufficiently large in diameter to admit the secondary spring-barrel within it, into the cavity of the fusee; a second ratchet of 75 teeth, at the outer edge, inclined in an opposite direction to those of the ratchet 55, and having the secondary spring-barrel attached to it, is placed contiguous to the great wheel of 96, plane to plane, and revolves on a tubular piece projecting from the plane of the great wheel; it does not appear how the click of the concave ratchet is placed to act with its teeth at the inner edge, but this click is no doubt placed on the plane of the large ratchet of 75, or on the barrel; the inner end of the secondary spring is hooked to the tubular piece on which the barrel and large ratchet attached to it revolve, and the outer end,

end, as uſual we preſume, to the ſide of the barrel within. There are two clicks to the large ratchet, one on each of its circumferences, which clicks are faſt to the plane of the frame-plate, together with their reſpective ſprings. The parts being thus connected, and the barrel inſerted into the cavity of the fuſee, the effect produced is this: ſuppoſe the key applied to the ſquare of the fuſee arbor to wind the piece up, the inclined teeth of the ratchet ſlide along the end of the click in this retrograde motion of the fuſee, during the act of winding, and no impediment occurs to free motion of the fuſee until the *garde* (or guard,) gives notice of the concluſion of winding; but let the key be withdrawn, and it will be obſerved, that the main-ſpring by its effort to relax, will urge the fuſee, in a direction contrary to the motion of winding, till ſome obſtacle oppoſe its motion; that obſtacle is the click of the concave ratchet, which if fixed in a ſtationary ſituation, would inſtantly arreſt the ſaid returning motion of the fuſee; but we have ſaid the click is fixed to the large ratchet or attached barrel, which contains, we will ſuppoſe, a relaxed ſpring; the returning motion of the fuſee, therefore, goes on, after the ratchet of 55 has caught its click, until the ſecondary relaxed ſpring in the little barrel is wound up as far as the ſtrength of the main-ſpring will wind it; the inner end of the ſecondary ſpring at that inſtant begins to act on the tubular projection of the great wheel, which may be called the barrel arbor, and urges it on as though the click had been fixed to the great wheel, and as though there had been no large ratchet, which Harriſon calls the perpetual ratchet, nor any ſecondary ſpring interpoſed between the firſt ratchet and the great wheel; and thus it is that the power is continually tranſmitted through the medium of an *intenſe* ſpring, after it has been firſt wound up from a ſtate of relaxation. Conceive again the key applied for the ſecond winding as before; the returning motion of the fuſee will now be but little, becauſe the ſecondary ſpring has been already wound up; but the effect of the contrivance here becomes evident; the ſecondary ſpring being previouſly wound up, the two clicks of the large ratchet of 75, to which the ſecondary ſpring-barrel is attached, keep it from relaxing, while the preſſure of the main-ſpring is taken off by the act of winding; the force of this ſecondary ſpring, however, will exert itſelf ſomewhere to return to its natural ſtate, and becauſe the motion of the ſpring is ſtopped at the outer end, by the juſt mentioned clicks preventing the returning motion of the large or perpetual ratchet, the inner end of it will exert its whole force on the pin of the tubular part of the great wheel, conſidered as the barrel's arbor, and will thus impel the great wheel for a limited time with the ſame force with which it was acted upon itſelf, when wound up to the extreme, that is, with the whole force of the maintaining power to which it becomes a temporary equivalent. Thus we ſee four ſprings were uſed by Harriſon, which we are told were all made by Maberley, except the balance-ſpring that required rubbing away till it was found of a proper ſtrength to regulate for mean time nearly; the temper was given to this ſpring and the ſteel pinions by a melted mixture of one pewter and fixteen lead; and to the balance-ſpindle by a mixture of one pewter and twelve lead, the latter of which mixtures, in a ſtate of fuſion, the author ſays, is equal to 567° of Fahrenheit.

The effect of the thermometrical-curb was increaſed by rubbing the ſides thinner, and decreaſed by thickening the edge with a burniſher.

The fuſee has $6\frac{1}{2}$ turns; the pivot-holes are all buſhed with rubies containing pieces of diamond at the bottom of each; and the pallets are of diamond. The fly at the fifth pinion is uſed to regulate the velocity with which the ſpring at the contrate-wheel is wound up every eighth part of a minute by the main-ſpring when unlocked. The dial-work is $\frac{112}{28} \times \frac{96}{32} = 12$, and the ſeconds are concentric by means of a wheel of 104 attached to the contrate-wheel driving another of the ſame number round an outer cannon in the centre.

The firſt time keeper which Harriſon made was in 1726, which Dr. Hutton aſſerts, did not err a ſecond in a month for ten years together; but the firſt time that one was publicly tried, was in a voyage to Liſbon, in the year 1736, which, being placed in a box, hung in gimbols, anſwered his expectation, and corrected the dead reckoning about a degree and a half; in conſequence of which, according to Dr. Mackay, the board of longitude granted him a gratuity, and deſired him to proſecute his labours.

In 1739, he finiſhed a ſecond piece more perfect than the firſt, and in 1749, according to Dr. Mackay, (but according to Dr. Hutton, in 1758,) a third, which was pronounced more ſimple in its conſtruction than either of the former; but his labours did not ſtop here; in 1761, his fourth piece, of which we have given a deſcription as nearly as we could without perſpective drawings, was produced for trial, and Mr. William Harriſon, the ſon, offered to take charge of it, in a voyage to and from Jamaica, which was accordingly performed in this and the following years. Mr. Robertſon, maſter of the Academy at Portſmouth, was fixed upon to take the rate of this piece, which he did, and reported that, on the 6th of November, 1761, at noon, it was 3^s ſlow after having loſt 24^s in nine days on mean ſolar time. The Deptford, in which ſhip the voyage was made, left Portſmouth on the 18th of the ſame month, and arrived at Madeira on the 9th of December following, when it was found that the reckoning was corrected by the time of the piece about a degree and a half. In the run from Madeira to Jamaica the reckoning was corrected 3°: and at the ſeveral iſlands, where the ſhip touched, the known longitudes agreed very nearly with thoſe given by the time-keeper. On Jan. 19th, 1762, the ſhip arrived at Jamaica; the time of mean noon was obſerved, by equal altitudes, at Port Royal, on the 26th of the ſame month, which, according to the piece, was $4^h\ 59^m\ 7^s.5$; but the original error on the 6th of November, 81 days, 5 hours before, was 3^s ſlow, this quantity, therefore, was to be applied as a correction, together with the accumulation of the daily error of $\frac{24^s}{9}$ in $81^d\ 5^h$, viz. $3^m\ 36^s.5$; this ſum of $3^m\ 39^s.3$ added to the time indicated, which, it has been ſaid, was $4^h\ 59^m\ 7^s.5$, make $5^h\ 2^m\ 47^s$ for the difference of longitude between Portſmouth and Port Royal; which determination was only 4^s of time leſs than the determination at Kingſton of the ſame, from the tranſit of Mercury over the ſun's diſc. This ſmall error in time correſponds to leſs than one nautical mile in the parallel of Jamaica.

The Merlin, on board of which the piece was now put, ſet ſail from Jamaica on the 28th of January, 1762, and experienced ſuch a violent ſtorm in the paſſage, as obliged young Harriſon to remove his piece into an expoſed ſituation; however, the ſhip arrived at Portſmouth on the 26th of March, and on the 2d of April the time of mean noon was found, from equal altitudes, to be $11^h\ 51^m\ 31^s.5$, to which its former error of 3^s, together with the accumulation of the daily error, viz. $\frac{24^s \times 147^d}{9} = 6^m\ 32^s$ being added, make the time of mean noon by the time-keeper $11^h\ 58^m\ 6^s.5$. From

From this report it appears, that from Nov. 6th, 1761, to April 2d, 1762, though the piece had experienced many violent agitations at sea, and had been exposed to great changes of temperature, the whole error amounted to only $1^m\ 53^s.5$, or $28\frac{1}{3}'$ of longitude on the equator, which quantity, (one second less than Dr. Hutton has stated), is not quite 18 nautical miles in the parallel of Portsmouth.

Though various objections were made to this trial, principally arising from the observations by which the longitude of Portsmouth and Jamaica had been ascertained, yet Harrison, we are informed, obtained a reward upon it from parliament of 5000l., and was ordered to make a second trial to Barbadoes. But previously to the second trial to the West Indies, the Board of Longitude, on the 17th of August, 1762, wished to place Harrison's piece in the hands of the astronomer royal, at that time Mr. Bliss, for trial at the Observatory, which wish was not complied with, by reason of some alteration to be made, probably by adding the cycloid-pin to aid the regulating spring; the same wish was repeated by the Board at their sitting on the 4th of August of the year 1763, which was again not complied with by the jun. Harrison, by reason of his not being yet sufficiently rewarded; however, on being desired to send the rate of going of his time-keeper, sealed up, to the secretary of the Admiralty, previously to his sailing, he consented to this request, and proposed to abide by the sealed rate on the trial to Barbadoes, which had been proposed. The annexed is a verbal copy of Mr. W. Harrison's declaration of the rate of going, or, more properly speaking, of the daily error of the time-keeper, to the Board of Longitude, dated Portsmouth, March 26th, 1764.

"My Lords and Gentlemen,

In obedience to your instructions, dated the 9th of Aug. 1763, I humbly certify that I do expect the rate of the going of the time-keeper will be as followeth; viz.

When the thermometer (Fahrenheit's, no doubt,) is at 42° it will gain 3 seconds in every 24 hours.

When the thermometer is at 52°, it will gain 2 seconds in every 24 hours.

When the thermometer is at 62°, it will gain 1 second in every 24 hours.

When the thermometer is at 72°, it will neither gain nor lose.

When the thermometer is at 82°, it will lose 1 second in every 24 hours.

Since my last voyage we have made some improvement in the time-keeper; in consequence of which, the provision to counterbalance the effects of heat and cold, has been made anew; and for the want of a little more time, we could not get it quite adjusted; for which reason the above allowances are necessary. This is its present state; and as the inequalities are so small, I will abide by the rate of its gaining, on a mean, one second a day for the voyage. I would not be understood, that it will always require so long time to bring those machines to perfection; for it is well known to be much harder to beat out a new road, than it is to follow that road when made. During the time of this experiment, the mean height of the thermometer shall be each day carefully noted down, and certified, which I will lay before the Board at my return. I am, &c.

WILLIAM HARRISON."

After having compared the time-piece with Mr. Short's regulator, in Surry-street, London, which had its error newly ascertained by an excellent transit instrument, Mr. Harrison junior went on board the Tartar on the 13th of February 1764, and proceeded to Portsmouth, where he again compared it with an astronomical clock in Mr. James Bradley's temporary observatory. It may not be foreign to our purpose to mention here, that the observatory just spoken of, was fitted up for the express purpose of observing the eclipses of Jupiter's satellites, as well as of keeping the clock in just time, in order that, to avoid future objections, the observations to be made by Messrs. Maskelyne and Green, at Barbadoes, on the same satellites, particularly the first, when compared with Bradley's, might ascertain the comparative longitudes of these two places, which was accordingly determined to be $3^h\ 54^m\ 20^s$.

Before leaving Portsmouth, which took place on the 28th of March 1764, Mr. Harrison took the rate of his time-keeper by equal altitudes, employed between the 29th of February and the 26th of March; and on April the 18th found, from comparing his observations of the sun at 4 P. M. at the ship, with the corrected time given by it, that the ship was at that instant only 43 miles eastward of Porto Santo, in consequence of which determination, sir John Lindsay, the master, steered accordingly, and saw the island in question before him at one o'clock the next morning, agreeably to expectation. On the 13th of May, the vessel arrived at Barbadoes, and on the four following days its error was ascertained by Messrs. Maskelyne and Green by equal altitudes of the sun, and also by a comparison with the astronomical clock at the observatory near Bridgetown; and it was found that the amount of the daily deviations from mean time was only 43^s in excess, or $10\frac{3}{4}'$ of a degree in longitude. Mr. Harrison set out on his return from Barbadoes in the New Elizabeth on the 4th of June; and, arriving at Surry stairs on the Thames, on July the 18th, found, from a comparison with Mr. Short's clock, the error of which had been ascertained on the very day, that the whole gain in the 156 days was only 54^s, allowing the sealed rate, of one second gain per day, as a correction: and it has been observed, that, if the allowances had been moreover made for the state of the thermometer, as stated in the declaration, the piece in that case would have been found to have been about 15^s only at variance with mean time, and this in the opposite extreme. Soon after this very satisfactory trial, a committee of seven scientific gentlemen and mechanicians were appointed by the Board of Longitune for examining the principles of Mr. Harrison's time-keeper, whose report was as follows: viz. "That Mr. Harrison has taken his time-keeper to pieces, in presence of us, and explained the principles and construction thereof, and every thing relative thereto, to our entire satisfaction; and that he also did, to our satisfaction, answer every question proposed by us, or any of us, relative thereto; and that we have compared the drawings of the same with the parts, and do find that they perfectly correspond." The committee were the Rev. N. Maskelyne, Rev. John Mitchell, Rev. William Ludlam, Mr. John Bird, Mr. Thomas Mudge, Mr. Larcum Kendal, and Mr. William Matthews. Mr. Harrison had then another 5000l. ordered him, with a promise that the residue of the whole parlimentary reward; which, by the act of queen Anne, was 20,000l., should be given him when a proper person could be found to execute his plan with equal success. Mr. Larcum Kendal, one of the committee already alluded to, undertook the task, and finished a time-piece on the same construction, or at least on the same principles, which was approved by Mr. Wales, in his voyage in company with captain Cook in the years 1772, 1773, &c. and which Dr. Hutton says performed even better than Harrison's, allowing for an accelerstion in its rate. In consequence of this success, the parliament, to which an appeal was made, ordered the residue of the proposed reward

 to

to be paid; in addition to which, the gratuities of the Board of Longitude, of the Eaſt India company, and of others, contributed to augment the whole ſum to about 24,000l.

It ſhould ſeem from Dr. Hutton's account, under the article *Longitude* of his Mathematical Dictionary, contrary to Dr. Mackay's authority in his book on the longitude, that the parliamentary rewards were made to the Harriſons by two equal payments of 10,000 l. each; to reconcile which accounts, we applied to Dr. Maſkelyne for authentic information, but, with his uſual reſerve, the Doctor declined giving us any information on the ſubject. The diſcrepancy in the dates of our two authorities, which agree in the whole amount, is not, however, of much importance. The compliment of the 20,000 l. was granted by parliament in the year 1774, and at the ſame time the new act paſſed for regulating the future rewards. For the credit of our ingenious countryman, we ſhould have been happy to cloſe our narrative of Mr. Harriſon's fourth time-piece here, but, as we profeſs to give an impartial detail of all the facts that have come to our knowledge, relative to the different trials made of it, we are under the neceſſity of adding a further notice, which is calculated to detract conſiderably from its merit, that might ſeem to have been already indubitably eſtabliſhed. Though the piece had agreed with the longitudes of Portſmouth, Jamaica, and Barbadoes, to a great nicety, and had alſo accorded very well with the known longitudes of ſome intermediate iſlands, yet it was by no means certain that the reſults would have been ſo exact if taken on intermediate days; or, in other words, a coincidence of the rate with mean time at the end of the voyage, was no proof that there muſt have been the ſame coincidence in every part of it: to put the piece, therefore, to a more rigorous teſt, the Board of Longitude, held April 26, 1766, came to a reſolution to have it examined at the Royal Obſervatory from nearly the beginning of May of that year, to the end of February of the year following; accordingly, Dr. Maſkelyne received the piece from the hands of Philip Stephens, Eſq. now Sir Philip Stephens, who was at that time ſecretary to the Admiralty, on the 5th of May, and, in the preſence of Captain Thomas Baillie, of the Royal Hoſpital, Greenwich; of Mr. John Ibbetſon, ſecretary to the Board of Longitude; and of Mr. Larcum Kendal already mentioned, it was depoſited in a deal box made purpoſely to contain it, with a glaſs cover made ſecure with putty. The box had two locks of different wards, and two keys to each lock; alſo a pane of glaſs in the ſide ſecured with putty; and whenever the piece was afterwards wound up, one of the keys was uſed by Dr. Maſkelyne, or one of his aſſiſtants, Joſeph Dymond and William Bayly, and the other by Captain Baillie, or one of the officers at Greenwich Hoſpital; and the conſtant formality of a written teſtimony was uſed, we are told, not only when the piece was wound up, but alſo when a compariſon of the rates of it and the obſervatory regulator was taken and regiſtered. Dr. Maſkelyne afterwards publiſhed the reſults, under the title of "The original Obſervations of the going of the Watch from Day to Day," in a quarto pamphlet, from which we have extracted, or rather deduced, the ſubjoined notices. The trial commenced on the 6th of May, 1766, and ended on the 1ſt of March, 1767, including a ſpace of 298 days, in which period the piece gained on mean ſolar time $1^h\ 10^m\ 27^s.5$; this accumulated error, divided by 298, gives $14^s.2$ very nearly, for the rate, or mean daily gain. On examining the different columns of the pamphlet, and the calculations grounded thereon, to aſcertain the daily errors, both of the regulator and time-piece, as compared with the ſolar tranſits properly equated, we find a daily gain of the piece on mean time, on June 8th, amounting to $30^s.2$, or more than half a minute; which greateſt deviation was when it was in a vertical poſition with XII. higheſt, and the thermometer at 60°; the barometer being at the ſame time at 29.9; but on ſome other days the piece was, on the contrary, loſing, particularly in January 1767, when the thermometer was down at the freezing point; on one day in particular, the 4th, the daily loſs was as much as $6^s.5$, when the poſition was horizontal with the face upwards. Dr. Hutton, ſpeaking of this trial, has ſaid in his Dictionary, that "the watch was now found to go faſter than during the voyage to and from Barbadoes, by 18 or 19 ſeconds in 24 hours;" this obſervation, however, is only accurate for the months of May, July, and about the end of October and beginning of November, and that when the poſition was horizontal and face upwards; but, even in this poſition, the temperature, in other months, produced conſiderable irregularity in the daily rate. Whenever the poſition was vertical, or inclined 20° from a horizontal line, the rate depended greatly on the hour of the dial plate that was uppermoſt, independently of temperature: from all which deductions, it is evident, that the time-piece wanted three adjuſtments to be made at the time of its trial at the obſervatory; viz. firſt an adjuſtment for an error of $14^s.2$ in the mean rate, ſuppoſing the gains to have been equable at equal intervals of time; ſecondly, an adjuſtment for poſition; and, thirdly, an adjuſtment for temperature; and, indeed, we find, according to Dr. Hutton, that Harriſon "had altered the rate of its going, by trying ſome experiments, which he had not time to finiſh before he was *ordered* to *deliver up* the watch *to the Board.*" Thus this trial, with all its precautions and formalities, was more calculated, perhaps, to prejudice the public opinion reſpecting the future dependence to be placed in a time-keeper, than to appreciate the intrinſic value of a well-regulated and well adjuſted machine; and we cannot forbear adding, as our concluding remark, that Kendal's time-piece, tried and approved by Mr. Wales, was made after Harriſon's model during or after this trial; and that the inventor's ſubſequent appeal to parliament was attended ultimately with the deſired ſucceſs.

CHRONOMETER, or *Time-keeper*, by Mudge. *Plate* XIII. of *Horology*, contains ſo much of the eſſential parts of Mr. Thomas Mudge's time-keeper, as will enable the reader to form a competent idea of its conſtruction and manner of performance. In the "Deſcription of the Time-keeper," publiſhed in 1799, by Mr. Thomas Mudge, Jun. there are nine plates, eight of which are taken up in exhibiting the different plans and ſections of the various parts ſeen in different points of view; they were drawn by Mr. Pennington, the original workman employed by the two Mudges, father and ſon; but inſtead of copying any of the plates, except our figures 6 and 7, which are from his Plate II., we have judged it to be more deſirable to procure original drawings of a time-keeper, from one in the poſſeſſion of the ſaid Mr. Pennington, who now lives at the corner of Orchard Row, Camberwell, and who has obligingly given us his aſſiſtance as well as permiſſion to analyſe the piece. It is not neceſſary to give a particular account of the calliper of Mudge's time-keeper, as it does not differ in any material particular from that of the chronometers by other makers; nor is there any thing worthy of particular notice in the fuſee, different from that of an ordinary watch, except that there is the auxiliary ſpring making with it a *going fuſee* of the ordinary conſtruction. (See the deſcription of Brockbank's *Chronometer.*) The barrel however, which contains the main ſpring, is very ſimilar to Harriſon's, and differs from ordinary barrels. *Fig.* 6, repreſents this barrel with the chain coiled round,

round, as it appears before it is wound up. A is the edge of the upper plate, and B of the pillar plate of the frame; the barrel is compoſed of two diſtinct parts, C and D, which together may be denominated an entire box, of which D is the body or box portion, and C the cover or lid; this lid C, which is attached to the arbor EF, is of itſelf, by Mr. Mudge, called the chain barrel, becauſe the chain is wound round it; and the box part, D, is alſo of itſelf called the ſpring barrel, becauſe it contains within it the main ſpring. A ſection of this *fig.* 6. is ſeen parallel to it in *fig.* 7, where the ſame letters imply the ſame parts; from the latter of which it appears clearly that the portion C of the greater diameter may revolve with its arbor EF, ſeparately from the other portion D. G in both *figs.* 6 and 7, denotes a ratchet-wheel made in form of a rim or broad ring, with its inclined teeth on the outer or convex circumference, and is ſoldered, or ſcrewed, to the lower end of the rim of the box D, in ſuch a way, that a very ſmall portion of the interior, or concave part, projects inwards into the box: this projecting part has a ſhoulder turned away in the lathe from its upper plane, which makes the part within the box thinner than the part without, as may be ſeen in *fig.* 7; the bottom of the box *a a* is detached, and is of a diameter juſt ſufficient to allow it to enter the inſide of the box; it has a correſponding ſhoulder turned in the lathe at the circumference on its lower plane, which ſhoulder reſts on the above deſcribed ſhoulder in the concave projecting part of the ratchet; the uſe of this contrivance is this; the box, with its looſe bottom in it, is placed on the plane of the plate A, and the bottom *aa*, perforated in the centre for the revolving arbor, is ſecured to it by two ſcrews or more, entering from the plate, ſo that though the box may be ſaid to be attached to the plate by its bottom, yet its rim is at liberty to turn along with the ratchet firmly faſtened to it, while the bottom is at reſt ſcrewed to the plate, and the motion of the ratchet will be free or impeded in proportion to the quantity of preſſure which the fixing ſcrews occaſion on the two ſhoulders already deſcribed. The parts being thus arranged, it is eaſy to conceive that a click, ſcrewed to the plate A at any convenient part of it, and taking into the teeth of the ratchet G, will hold the box, or ſpring-barrel, from going in a retrograde direction, as well as if the box itſelf had been ſcrewed to the plate A, but it will ſtill be at liberty to revolve in the contrary direction on the application of any external force to it. Suppoſe now the outer end of the ſpring, hooked as uſual, to the interior ſide of the barrel or box oppoſite D, while the inner end is hooked on a pin in the arbor within the box alſo; the conſequence will be, that the chain, which is coiled round its barrel or lid C, being wound away by the fuſee, in the act of winding, will pull the arbor round, and its force will apply directly to the interior end of the main ſpring firſt, becauſe this is hooked to the arbor, and the coils of the ſpring will follow one another ſucceſſively up to the centre, as the intenſity of the ſpring is increaſed by winding; whereas, in ordinary watches, where the ſpring-barrel itſelf revolves without the arbor, the outer end of the ſpring is firſt acted upon in winding up, and the coils near the centre are laſt affected by the force that winds. When the ſpring requires to be ſet up or down, it is done by turning the ſpring-barrel and ratchet together with the contained ſpring, while the click is raiſed from the teeth of the ratchet, the arbor of the chain-barrel then being ſtationary, or revolving no otherwiſe than according to the ſlow motion which the train regulates. The chain is wound round the fuſee in a direction which actuates the wheels of the train in a backward manner, compared with the motion of an ordinary train, which direction of motion requires an additional wheel in the dial-work; for a ſmall wheel of 45 fixed to the arbor of the contrate wheel drives another of the ſame number of teeth in a proper direction for indicating ſeconds, on a ſeparate graduated circle, at a diſtance from the centre of the face; nor is the ſecond, uſually called the centre wheel, placed in the centre of the hour and minute circles, as is common in watches; though oppoſite the centre of the face; but its prolonged pivot bears a minute wheel of 52, driving a ſimilar detached minute wheel, and alſo an attached pinion of 8 driving an hour wheel of 96, both which driven wheels have cannons to carry their reſpective hands round two concentric circles, placed at the other ſide of the centre of the dial. This method of placing the hands allows the contrate and centre wheels to have ſmall pivots. The numbers of the movement publiſhed by Mudge are as follow: viz. the great wheel has 100 teeth, the pinion acting with it 20, the centre wheel or ſecond wheel 120, the next pinion 16, the third wheel 120, the pinion driven by it 15, the contrate wheel 120, the pinion driven by it 12, balance wheel 15, pallets 2; whence it ſeems that the fuſee revolves in $\frac{100}{20}$ or 5 hours, and the contrate wheel in $\frac{120}{16} \times \frac{120}{15} = \frac{60}{1}$, or 60 times in the hour, and the value of the train is, according to our method of eſtimating Harriſon's train, $\frac{120 \times 120 \times 120 \times 15 \times 2}{16 \times 15 \times 12} = 18000$ vibrations in each hour, or five in each ſecond. With this movement a fuſee with $7\frac{1}{5}$ turns or ſpirals in the groove, actuates the piece 36 hours; but there is a face laid down in Mudge's book for a continuance of eight days, the circles for the hours and minutes in which are at oppoſite ſides of the prolonged pivot of the centre wheel arbor, and the hour circle counts up to 24, which is certainly more convenient for aſtronomical calculations, than one with only 12 hours. On ſearching for an account of the train of this conſtruction, we are only informed, by Mr. Mudge, jun. that ſuch of the time-keepers as went eight days, were charged higher than thoſe which continued at one winding only 36 hours; but the numbers of the movement are not given by him; on application to Mr. Pennington, however, we have been favoured with them, which are as follow, viz. great wheel 108, pinion on the centre wheel 12, centre wheel 128, pinion following 12, ſecond wheel of the train, or third of the whole movement 120, pinion driven by it on the next arbor 12, contrate wheel 120, pinion following on the balance wheel arbor 12, crown wheel 15, pallets 2; ſo that the value of the train is $\frac{128 \times 120 \times 120 \times 15 \times 2 = 55296000}{12 \times 12 \times 12 \; 1728} = 32000$, on a ſuppoſition that the centre wheel revolves in an hour; but we find from the dial-work, which has what is called *borrowed minutes*, that this wheel revolves in $\frac{112}{63}$ of an hour or in 1.7 hours, therefore $\frac{63}{112}$ of $32000 = 18000$ is the true train by the wheels and pinions before us; the hour hand revolves in $\frac{135}{10}$ of $1^h.7 = 24^h$; and the fuſee revolves in $\frac{112}{63} \times \frac{108}{12}$ of an hour, which is $= 16$ hours; therefore a fuſee with juſt 12 turns will continue to go eight days, as was intended.

Fig. 1. of *Plate* XIII. is a perſpective view of the cock of Mudge's time-piece, ſuppoſed to be detached from the upper plate of the frame: the dotted ſpiral round the centre is the balance regulating-ſpring, to which there is a correſponding one underneath, called the compenſation-ſpring.

Directly over these springs is placed a smaller concentric frame supported by three pillars, *a, a, a*, on the principal cock, and bearing four friction-rollers, of which the centres are marked by four points at the extremities of the dotted spiral; these points are here supposed to be demitted from the same plate to the large cock, as the former is taken off to show the spiral-spring; the pivot of the balance-arbor runs in the central point where the four rollers nearly meet, and touches the circumference of each, so as to produce a rotatory motion in each that lessens the friction at the pivot; *b b* is a metallic sliding-piece filed away on the side next the centre, to avoid the regulating-spring, and placed on the plane of the cock, to adjust one of the curb-pins for regulating the piece, which it carries underneath it; the cock has an oblong slit in it near the screw at *b*, for the pin to move backwards and forwards during the act of adjustment, and the slider itself has two oblong slits, one at the said screw, and the other at one of the little frame pillars, which slits not only admit of a longitudinal motion of the slider, but also keep it in its due line of position during the motion of adjustment: at *c* is an arbour, square at the end to admit a key, but round below, and has a fine screw at the remote end, which presses against a stud *d* in the cock, where is a third opening for the stud, thereby moving the slider in consequence of the part *e*, which is turned up at its end, being tapped to suit the screw of the arbor of adjustment: on the middle of the said arbor is a nut between *e* and *c*, divided into 30 on its edge, which is pointed to by a fixed line on a stationary piece adjoining, through which the arbor passes. There is, moreover, a scale, *f*, attached to the large cock, to which a line on the slider near *e* points as an index of adjustment, and moves one space for every entire turn of the screw, which is an addition of Pennington's to the original construction. *g* is an horse-shoe-spring placed on the cock to force back the slider, when the screw has a retrograde motion. These parts and their uses, it is presumed, will be easily apprehended from our drawing, without the variety of views which Mr. Mudge has given in his plates. The slider is held down to the plane of the cock by the screw near *b* at the curb-pin, and also by a collet going over the stud *d*, and pinned on. There is a second curb-pin fixed on a detent, or straight piece of steel, riveted to the under side of the piece *h*, and crossing the slider at right angles; this curb-pin is borne by the interior extremity of the detent, and the adjustment is made by the screw and studs *i* screwed into the cock, and fitted sideways into two notches in the piece *h*; the screw on *h*, which holds the whole down, passes through an oblong hole, covered by its head, to admit of the adjustment of distance. The mechanism of this second curb-pin, we fear, will not be very intelligible, as some of the parts are necessarily out of sight: *k* is the stud of the regulating spring, and *l* a piece made purposely to cover the second screw of the large cock, which screw, therefore, cannot be taken out for dismounting the cock until this cover is taken off, and the cover itself cannot be removed till the regulating spring-stud is previously taken off: this precaution was necessary to prevent the derangement or breaking of the balance regulating-spring, one of which would follow, if the cock were dismounted without the stud being first unscrewed; the nature of the precaution is this; the cover *l* moves on its centre, below *b*, as on a pivot, and the round part at the upper end covers one of the two screws of the cock, until the stud, embraced by the semi-circular fork of the other end, is removed, when the cover *l* then is at liberty: the other corresponding screw for fixing the cock is visible at the opposite projection above *c*. *Fig.* 2, represents the second balance-spring and mechanism of compensation for the effects of heat and cold, as they appear when the cock in *fig.* 1. is removed from the upper plate of the frame; *a a* is a piece of brass screwed to the plate by the three screws *d, d, d*; *e* and *f* are two similar compensation-bars, composed of brass and steel soldered together, with their positions reversed; that is, the piece *e* has the brass side next to *c*, and the piece *f* has the steel side next to *f*: these compound pieces, seen in a detached state in *fig.* 3, with their interior curved ends passing each other, are screwed, each by two screws, at their outer ends, to the similar pieces *g* and *g*, which are themselves screwed to the long piece *a a*, but in such a way that they are adjustable, when their fixing screws are not home; the adjustment is made by the two similar horizontal screws at *h* and *h*, which fit the studs that appear at *i* and *i* in the oblong apertures of the pieces *g* and *g* left for the studs; and by these, together with the narrow apertures, and two other smaller studs *k* and *k*, one at each interior end of the said pieces *g* and *g*, is preserved the parallelism of the motion of adjustment: *l l* is a lever or detent, carrying a curb, or piece with two pins at the upper end, a little distance from the stud *m* of the regulating spring, and having a little curve to avoid the balance-verge, together with two short levers or tails, near the rounded projection of the cocks *b* and *c*; this detent is fixed on an arbor, which is pivoted above into the cock *b*, and below into the foot *n* of the cock *c*, which is let down, out of sight, through an aperture in the plate; the lever of the detent, however, is prolonged back to a considerable distance behind the cock to the end *q* of the cross-piece of *a a*, on which is described a portion of a circle divided into 20 equal spaces, to indicate, as a thermometer, the situation of the curb at any particular time; which is another addition contrived by Pennington. Now the action of the compensation-bars in the time-keeper, denominated *blue*, is this; because brass is more elongated by heat, and also more contracted by cold than steel, the former will be longer in summer and shorter in winter than the latter; the consequence of which will be, (as we have already said, when speaking of Harrison's compensation mechanism, from which it should seem the principle of this is borrowed,) that the metal most elongated will become convex in hot, and concave in cold weather; for instance, the compound bar *e*, with the brass side next to *e*, will become concave in cold weather on the brass side, and, its remote end being fast by the screws to the fixed piece *g*, the interior end will move forward to form the curve and press below the remote tail-piece of the detent, which detent will therefore move and bring the curb towards *o*, the other compound bar *f* in the mean time becoming convex on the side *f*, will make way for the motion of the other tail-piece that points to *e*, by falling back at the same rate with which the other bar moves forward; but in hot weather the contrary will take place, i. e. the interior end of the piece *f* will come forwards and press on the other remote tail-piece, and the end of the piece *e* will give way for the backward motion of the tail-piece pointing to *f*, the curb in the mean time having its motion in a direction towards *p*: the former of these two contrary motions of the curb will shorten the spiral-spring, or, at least, the effective portion of it, as the curb limits its action, and the latter will lengthen the same: but it is well known, that a short spring has greater force than a long one, *cæteris paribus*; likewise, that the altered momentum of the balance retards the rate in hot weather, and *vice versâ*; hence, the increased force of the spring in cold weather thus becomes a compensation for the sluggish motion of the balance occasioned by the same natural cause, and the contrary in the opposite extreme of temperature. Mr. Mudge junior might seem to have been guilty of an error

error in his "Defcription, &c." page 169, of this part of his mechanifm, but he is there defcribing the time keeper *green;* the compenfation-bars in which were made to act with the tail-pieces of the detent, which point refpectively *towards* them inftead of thofe which point *from* them : the nature of the action of the tail-pieces in *blue*, is, on the contrary, as we have defcribed, and as is clearly feen by the view we have given of the pofition of thefe bars in *fig.* 3. There is an error in the account by Mudge of this part of his mechanifm, where he afferts, that "the natural effect of heat is to leffen the momentum of the balance: and of cold to increafe it." We beg leave to obferve on this, perhaps unguarded, affertion, that whatever caufe enlarges the dimenfions of the balance muft undoubtedly increafe its momentum; and that heat has this effect is evident from the curve formed by the fuperior elongation of brafs compared with the lefs expanfible metal, fteel. Hence, the fpiral is fhortened by the curb in fummer and lengthened in winter.

In *Fig.* 4 (*Plate* XIII.) *a* is a cock in which the upper pivot of the upper pallet runs; the cock *b* is that in which the lower pivot of the lower pallet runs; *c* is the cock, on the nofe of the potence, on which both thofe pivots run that are near the axis of the balance-wheel; *d* is the cock in which one of the balance-pivots runs; *e* the cock for the other pivot of the balance-wheel; and *f* the potence fcrewed to the under fide of the upper plate, and bearing the fmall cocks, nearly in the relative pofitions in which they ftand in the figure; it may be proper to add, that the femicircular vertical excavation in *e* is to admit the arbors of the pallets within it, and that the pivot holes on thefe cocks are all jewelled.

Fig. 5 (*Plate* XIII.) exhibits a perfpective view of the balance, on an enlarged fcale, which is in the original of half an inch diameter, together with the auxiliary fprings which are fubftituted for the maintaining power, the balance-wheel, and the pallets. A B is the balance, and E F its verge, fhaped like a crank, of which the pivots I and K run in two fyftems of rollers, that have each a little frame, one of which has already been defcribed under our defcription of *fig.* 1, to which the lower one, placed at K, and fupported by a pillar fixed to the upper plate, is fimilar: one of the croffes of the balance bears a piece, M, to counterpoife the crank of the verge, and to keep the balance in equilibrio. C is the ftud of the regulating fpring, placed, as we have already feen, on the cock of the balance; and D is the ftud of the compenfation-fpring, fcrewed to the upper plate of the frame; thefe two fprings are both attached by their interior ends to the upper part of the verge above the crank, and have thin helices wound in the fame direction. The reafon why the verge has the fhape of a crank, is, that the little cocks or bearing pieces, reprefented in *fig.* 4, may have room for being fixed in their refpective fituations to catch the pivots of the balance-wheel arbor, and of the two pallet arbors, *c d* and *g h*, which arbors are exhibited in *fig.* 5, without their cocks, in order that the acting parts of the efcapement may be prefented to view; *a* is a pin, projecting from the upper bend of the crank verge, which in its motion meets with another longer pin, *b*, made faft to the arbor of the upper pallet, which pallet is feen a little curved with a fmall bend or hook at the outer end, between the letters *c* and *d*: this pallet-arbor has the upper auxiliary fpring fixed to it by its interior end, the outer end being pinned to the ftud at H; G is the pallet-wheel with its arbor difcontinued near the place where the contrate-wheel pinion is fixed. Mr. Nicholfon has given a very good account of the action of Mudge's efcapement in the 2d volume of his Journal, 4to feries, page 57, but has reprefented the fhape of the tooth in this balance-wheel fimilar to that in an ordinary watch, which, indeed, Mr. Atwood had done before him in the Philofophical Tranfactions of 1794; thefe authors have alfo omitted to mention the fpring of compenfation, which we here notice, becaufe their readers would otherwife be at a lofs, from the view of the figure, to know how the compenfation for temperature is effected, or, indeed, whether there is any at all; their object being only the account of the fprings as they related to the balance and efcapement. Pennington, who made the drawing for Mr. Atwood's paper, tells us, however, that the fhape given to the teeth is not of much importance. There is another pin, *e*, at the bottom of the crank, fimilar to *a* above, and alfo a fecond pallet-arbor, *g h*, carrying another pin, *f*, and a fecond auxiliary fpring, the outer end of which is pinned into the ftud I: the helix of this fpring is wound in a direction contrary to that of the upper auxiliary fpring. We have endeavoured to give fuch a perfpective reprefentation of the mechanifm of efcapement, together with the balance and compenfation, in one figure, as might exhibit to view all the parts of action; and the effect produced when the time-keeper goes, may be thus defcribed.

There are fix fprings employed in the time-keeper: the main fpring, the fpring of the going-fufee, the regulating or pendulum-fpring pinned at C, the fpring of compenfation pinned at D, and the two auxiliary fprings on the two pallet-arbors; let us fuppofe all thefe fprings exactly in their natural ftate of quiefcence, and that the crank verge, and pins on the two bends of it, are fo adjufted as to reft quietly againft the pins *b* and *f* of the pallet-arbors: alfo let the two pallets be at liberty, one remaining in the fpace diametrically oppofite the acting tooth which refts againft the other, which will be the cafe as the number of teeth is an odd number (15); in this fituation all the arbors will remain at reft till fome force is impreffed on the balance-wheel, provided the piece be fuffered to lie on a table; now wind up the main-fpring, and the fpring of the going-fufee will be firft put into a ftate of intenfity, and then the power will be tranfmitted through the train, with fome occafional variations of intenfity, arifing from the unavoidable friction of the teeth of the train, up to the balance-wheel, which will be impelled forward, till, pufhing againft one of the pallets, fay the upper one, it meets with fome refiftance from the auxiliary fpring on the pallet-arbor; however, the power of the main-fpring is fufficient to wind this auxiliary fpring up till the tooth of the balance-wheel, fliding on the concave fide of the pallet, is ftopped by the little hook at its extremity, which hook of the pallet now acts as a detent, and arrefts the further motion of the pallet-wheel as urged by the main-fpring; the quantity that the pallet-arbor revolves during this fhort action of the pallet-wheel, we are told, is about 27°. Now all is at reft again, and would continue fo, if no external force were to put the balance in motion: let therefore an impulfe be given to the balance fufficient to make it move through a femi-vibration, which in one of the original machines was 133° with one of its balances, and 119 with another; during this femi-vibration, the pin *a* of the crank catches the pin *b* of the pallet-arbor at the 27th degree from the ftate of quiefcence, and confequently difengages the pallet, and goes on winding up the auxiliary fpring the remaining 106°, the balance-wheel in the mean time running on, on being difengaged from the detaining pallet, by the impulfe of the main-fpring, till it arrives at the hook of the lower pallet; but during this unreftrained motion, it has no connection whatever with the balance; on which account it is that the efcapement is called a detached one; detached, as it relates to the main-fpring, except for the moment of unlocking,

locking, which is not more than $\frac{1}{25}$th part of the time of a vibration, but not detached, as it relates to the auxiliary ſpring, which is uſed as a ſubſtitute for the maintaining power; for we have ſeen that the pin in the crank of the balance verge impels the pin in the pallet-arbor all the time that the auxiliary ſpring is wound through a ſpace of 106°. The balance wheel by the impulſe of the main-ſpring having now urged the lower pallet till it is detained by the bend in its extremity, the pin *f* in the lower pallet-arbor has alſo in its turn been moved 27° from the place of reſt, in which ſituation it is now ready to be caught by the pin *e* in the lower bend of the crank verge; at length the balance begins to return from the point at 133°, the extremity of its vibration, and in its turn is impelled by the pin *b*, acting againſt the pin *a* of the crank, during the whole ſemi-vibration of 133°, ſo that it is itſelf impelled 27° more than it impels the pin, and the difference of the continuation of the two alternate impulſes conſtitutes the quantum of maintaining impulſe, that keeps the piece in continual motion; which quantum, in fact, is a deduction from the retarding force in the latter ſemi-arc of vibration, rather than an addition to the impulſive force in the firſt ſemi-arc. The balance-crank in its return on paſſing the point of original quieſcence, has done with the ſpring of the upper pallet, which now remains in the poſition we at firſt found it; but when the crank has paſſed the point of original quieſcence the ſpace of 27°, its pin *e* meets with the pin *f* of the lower pallet-arbor, which is in its turn impelled by the ſaid pin *e*, the ſpace of 106°, exactly as the former one was; the former, or upper pallet, in the mean time being again carried forward 27° by the next following tooth of the wheel; at length this ſemi-vibration is complete, and the balance-crank returns, driven by the pin *f* through the whole 133° to the point of its ſpring's quieſcence as it was before by the pin *b*, and thus the proceſs is finiſhed through two ſucceſſive excurſions; which proceſs may be conceived to continue for months, or even years, without interruption. Some of the balance-wheels were made of tempered ſteel and ſome of braſs, and the acting portions of the pallets of flint, agate, ruby, or ſapphire. The two ſlender ſprings within the crank, which have been juſt deſcribed, are denominated *auxiliary* ſprings, becauſe they *aid* the two other ſprings in the reſpective returning parts of each vibration, and in this point of view may be conſidered alſo as regulating ſprings, but, being only $\frac{1}{20}$th of the ſtrength of each of the others, are too weak of themſelves to perform this office without the addition of the other more powerful ones, one of which has its effective length conſtantly, though very ſlowly, changing by the ſucceſſive changes of atmoſpheric temperature, which is the reaſon why we called it the compenſation-ſpring.

It is of the utmoſt importance that all the four ſprings of the balance ſhould be at their reſpective points of quieſcence when the balance is at reſt, otherwiſe the law of their forces, which is aſſumed to be directly as their tenſions, will not be the ſame in all, and ſome may be accelerating while others are retarding, whereas they ought all, like one ſpring, to accelerate and retard the balance conjointly in every part of the vibration, unleſs, indeed, the large ſprings are found not to be iſochronal, and the ſmall ones have their points of quieſcence ſo placed as to effect a compenſation, which Mr. Atwood, in his ingenious paper of Feb. 27, 1794, in the Philoſophical Tranſactions, has ſhewn to be a feaſible adjuſtment. For inſtance, if the point of quieſcence of each of the auxiliary ſprings, or even of one of them, be placed ſomewhere in the firſt ſemi-arc of vibration of the balance, the acceleration effected thereby will be leſs in this than the retardation will be in the following ſemi-arc; in conſequence of which the time-keeper will go ſlower; but if the point of quieſcence of the auxiliary ſpring be in the latter ſemi-arc of vibration, the contrary will be the caſe, that is, the time-keeper will accelerate its rate; nay, if the quantity of deviation from the exact point of quieſcence be only one degree of a circle, the ſame author has calculated that where the balance is of one inch radius, and of a correſponding given weight, the daily gain or loſs will be about $19\frac{1}{2}^{s}$, and the quantity increaſes with the diminution of the arc of vibration; ſo that if the arc of vibration were to become 60°, in one caſe the daily loſs would be $44^{s}.33$, and in the other the daily gain would be $43^{s}.6$; which conſideration ſhews the imperious neceſſity of having the points of quieſcence of all the ſprings exactly adjuſted; and alſo that the pins in the pallet-arbors be ſteadily fixed; for an alteration in their poſitions is in fact an alteration in the quieſcent points of the auxiliary ſprings.

If we were to reaſon from theory, we ſhould be diſpoſed, from the conſideration we have given this mechaniſm, to ſay, that the principle upon which it is conſtructed is excellent, inaſmuch as the impulſes given to the balance, and the oppoſitions made to it during its vibrations, are in proportion to the diſtance from the point of reſt at all times, agreeably to the laws of gravity in a pendulum; the diſcontinuance of the retarding force for a ſpace of 27° in each excurſion, deranges as little as may be the ſcale of varying forces by which the regulation is effected; whereas in the other detached eſcapements, where the impulſe from the train is momentary, ſuch impulſe, to be powerful enough to maintain the continual motion of the balance, may be ſuppoſed to partake of the nature of a *jerk*, and to derange the regularity of the ſcale of forces, according to which, the balance-ſpring ought naturally to act; however, in practice it has not been proved that this conſtruction exceeds ſome of the more ſimple ones; but we will not undertake to affirm, that the aſſertion is quite accurate which ſays, that the great number of pivots requiring oil, and the various ſprings that require adjuſtments for time, temperature, power, and poſition render it extremely difficult to obtain a permanent rate. It is ſaid by the younger Mr. Mudge, that his father conceived the idea of making a time-keeper, and had organized his notions reſpecting its conſtruction, ſo early as Auguſt 1771, before he knew the conſtruction of Harriſon's; which ſeems probable, from various obſervations made in his "Thoughts on the Means of improving Watches," publiſhed in 1763, and written ſome time before; but were we diſpoſed to judge alone from a compariſon of the principles of his and Harriſon's time-keepers, we ſhould at leaſt ſay, that there is a remarkable reſemblance, almoſt too great for accidental coincidence; the principle of the compenſation mechaniſm is preciſely the ſame, and the auxiliary ſprings, though greatly different in their mode of acting, the one being before and the other behind the balance-wheel, the one wound up eight times in a minute, and the other once at each vibration, yet the object is the ſame in both, namely, to give a regularly modified impulſe to the balance, which balance again has a great momentum in both conſtructions, in conſequence of its enlarged dimenſions. Mr. Mudge, in a letter dated Plymouth, Oct. 5, 1775, and addreſſed to his excellency count Bruhl, his friend, ſays, "I do not think it difficult to deduce from reaſons, *a priori*, that there is one diameter (of a balance), with a proportionable weight, by which a greater momentum will be procured than by any other; and that you will loſe momentum either by increaſing or diminiſhing that diameter;" he does not, however, give thoſe reaſons, but has recourſe to experiment. The original balance was ſuppoſed to be too heavy in proportion to its diameter, a larger but lighter one

was

was therefore made and tried, but the alterations neceſſary to be made in the cock rendered the trial doubtful, though the opinion entertained was in favour of a diminiſhed momentum being occaſioned by the alteration; a third was then made, one-tenth of an inch bigger than the firſt, and nearly four-tenths leſs than the laſt, " and I find (ſays our author) upon comparing the diameters, vibrations, and weights of the two (laſt made) that the momentum of the leaſt is to the momentum of the biggeſt as 9 to $7\frac{2}{3}$ nearly." The ſubjoined are the data and calculations on which the above concluſion was founded; viz.

leaſt balance
Inches
Diameter 2.15 × 266° = 571.9 = the velocity
Vibration 266°
Weight 56.5 grains
Then 571.9 × 571.9 = 327069.61 × $56^{gr}.5$ = 18479433 = momentum.

Inches
Diameter 2.47 × 238° = 587.86 = the velocity
Vibration 238°
Weight 45.5 grains
Then 587.86 × 517.86 = 345579.3796 × $45^{gr}.5$ = 15723862 = momentum.

Let it be remarked here, that Mr. Mudge has ſuppoſed all the weight at the circumference of the balance, and has aſcertained the velocity from the diameter, which we apprehend ſhould have been from the radius or diſtance from the centre of motion, which mode would not indeed affect the relative, but would double the real velocities; alſo the ſquare of the velocity is multiplied by the weight, contrary to the opinion of thoſe who aſſert that the ſimple velocity ſhould be uſed as a multiplicand for the weight uſed as a multiplier, in order to effect a product equal to the momentum. According to this latter rule, if we take the double velocity as before, the reſpective momenta will be 371.9 × 56.5 = 32312.35 and 587.86 × 45.5 = 26747.33, which reſults are very nearly as 6 to 5.

It does not appear, notwithſtanding the above calculation, what was the relative power derived from the auxiliary ſprings, conſidered as a maintaining power, compared with the regulating power, which we have ſeen was 1 : 80 in Harriſon's time-keeper; nor is it quite certain, though very probable from the account, that the balance, with the greateſt momentum, was uſed in the trials of the going of the firſt time-keeper, on which an application was made for the parliamentary remuneration. Pennington found, from ſome experiments on a time-keeper that ſtopped in a voyage, that the neceſſary force of a main-ſpring ſhould be to the force juſt ſufficient to keep the piece in motion at firſt, as $17\frac{1}{2}$ to $10\frac{1}{2}$: i. e. when $10\frac{1}{2}$ oz. will produce a continuance of motion at firſt, 7 oz. more muſt be added for foulneſs in wear. Theſe were the exact proportions in *green*, though in *blue* they were found ſomewhat different.

Though Mr. Mudge had made and approved his firſt time-keeper, previouſly to Harriſon's having obtained his laſt 10,000l., the complement of his rewards, which ſum was granted by parliament in 1774, yet he was unfortunate enough to omit making application for the trial of his time-keeper till the act had paſſed, which limited the whole reward to 10,000l., or one half of that propoſed by the act of queen Anne, and alſo rendered the limits of trial more circumſcribed; the latter of which circumſtances rendered the attainment of even a portion of the diminiſhed reward more difficult, than the attainment of the whole great reward which Harriſon was fortunate enough to obtain by his indefatigable perſeverance. The act of queen Anne allowed to Harriſon's trial a voyage of only ſix weeks, at the end of which, if his time-keeper was found to have kept time within four minutes of error, or one degree of longitude, he might claim a portion of the reward thereon; but the time ſpecified in the act of 1774 was ſix months, during which, the error was not to exceed four minutes, for the ſmalleſt portion of the reward. In the four trials made of the time-keepers of Mr. Mudge by Dr. Maſkelyne, from the years 1776 to 1790, the firſt of which trials was of N° 1, in 1776, 1777, and 1778, and the ſecond, third, and fourth of the pieces denominated *blue* and *green* in 1779 and 1780, again in 1783 and 1784, and again in 1789 and 1790, it appeared from the Doctor's reports to the Board of Longitude, that none of the time-keepers had kept time within the limits preſcribed by the act of Geo. III. On the 1ſt of March, 1777, however, the aſtronomer royal reported to the Board, that the (1ſt) watch made by Mr. Mudge had gained only 1^m 19^s in 109 days, in conſequence of which, it was reſolved, that a letter be written to the Navy Board to pay Mr. Mudge 500l. to enable him to finiſh two more watches on a ſimilar conſtruction, which was deemed preferable to any other that had been previouſly tried; but after this, the main-ſpring of this piece broke, and on being replaced, the piece was found, on a trial of 15 months, commencing on Nov. 11, 1776, to have gained daily $8^s.6$ at the end, more than at the beginning of this ſecond portion of the trial. With reſpect to the three trials of the time-keepers, *blue* and *green*, we ſhall have occaſion to ſpeak of them hereafter. Since the publication of the " Narrative" by Mr. Thomas Mudge junior, it is well known what the difficulties were that Mr. Mudge encountered from the oppoſition which the Board of Longitude raiſed againſt him in his appeal to the Houſe of Commons, after his memorial to the Board had been unſucceſsful on the 11th of June, 1791. To inquire into and aſcertain the comparative merits of Mr. Mudge's time-keeper, however, a committee was appointed by the houſe in conſequence of the appeal conſiſting of the following honourable members: viz. Mr. Pitt, Mr. Fox, Mr. Ryder, Mr. Bragge, Sir Gilbert Elliot, Mr. Gregor, Sir George Shuckburgh, and Mr. Windham, of whom Sir George Shuckburgh was conſidered as the friend of the Board of Longitude, and was therefore candidly propoſed by Mr. Windham to witneſs all the meaſures about to be taken. The committee very properly directed their attention, in the firſt inſtance, to two material objects; 1ſt, to appoint a ſub-committee of ſcientific gentlemen, and men of practical ſkill in mechanics, to examine and report their opinion of the principles upon which the conſtruction was founded; and ſecondly, to aſcertain by a compariſon with other chronometers the accuracy which Mr. Mudge's time-keeper had given proof of in its actual meaſurement of time. The ſub-committee nominated was compoſed of the following liſt: viz.

The Biſhop of St. David's, Mr. Atwood, Mr. De Luc.	Scientific Gentlemen.
Mr. Ramſden, Mr. Ed. Troughton.	Mathematical Inſtrument Maſters.
Mr. Holmes, Mr. Haley, Mr. Howells.	Watch Makers.

This ſub-committee after due examination made the ſubjoined report to the ſelect committee, viz.

" We whoſe names are underwritten, to whom it hath been referred, by a Select Committee of the Honourable Houſe of Commons, to receive confidentially from Mr. Mudge, a communication of the principles of his time-keeper, and to report thereon, being aſſembled at the houfe of his Excellency Count Bruhl, in Dover Street, on Tuefday the 14th inftant, did caufe a time-keeper, which was produced to us as one of the two made by Mr. Mudge, and fubmitted to trial at the Royal Obfervatory at Greenwich, for twelve months, from June 1789 to June 1790, to be taken to pieces in our prefence, by Mr. Matthew Dutton; and having carefully examined the parts of the fame, we find a contrivance in it for deftroying the inequalities of the maintaining power derived from the main fpring, which as far as we know and are informed is altogether new; and having confidered the fame, and put many queftions concerning it to Mr. Mudge, jun. and Mr. Matthew Dutton, we are of opinion, that the faid contrivance is well calculated for producing the defired effect, and that a difclofure of it may conduce to confiderable improvements in the art of making time-keepers. We moreover declare that we find great fkill and ability difplayed in every part of the workmanfhip, as well as much ingenuity in this particular invention. At the fame time it is our opinion, and we think it our duty to declare it fo to be, that no judgment can be formed of the exactnefs of any time-keeper by theoretical reafoning upon the principles of its conftruction, with fuch certainty as with fafety to be relied upon, except it be confirmed by experiments of the actual performance of the machine.

Samuel St. David's,
George Atwood,
Jesse Ramsden,
Edward Troughton,
John Holmes,
Charles Haley,
William Howells,
J. A. de Luc."

Dover Street,
the 20th of May, 1793.

Notwithftanding this report and the teftimonies produced by Mr. Mudge in favour of his three time-keepers, one made in 1774, and the other two in 1777, from regifters kept by Doctor Mafkelyne, Doctor Hornfby, Count Bruhl, Doctor (now Baron) Zach, of Saxe Gotha, and Mr. Dutton, who had been partner with Mr. Mudge, yet the committee, at a lofs for an unerring rule by which to afcertain at all times an exact rate to be depended upon in future trials, declared it as their opinion that fome of Mr. Arnold's chronometers, particularly No. 36 and No. 68, "had gone with a degree of accuracy greater than could be fhown on any correfponding trial of Mr. Mudge's;" but in another part of the report of the felect committee, which is too long to be copied at full length, it is faid, alluding to the foregoing report of the fub-committee that "in virtue of this report, and of fuch other evidence as the inquiry has furnifhed, your committee have no difficulty in declaring, that they confider the improvement in queftion fufficiently afcertained, and as likely to conduce to advantages fufficiently important to attract the notice of Parliament;" then, after the attention of parliament had been directed to the circumftances of a life, fpent in hope of benefiting the public, more than of enriching the individual, the report concludes with thefe words; viz. "For thefe confiderations, joined to thofe above fet forth, your committee think themfelves authorized to recommend the petitioner to the attention of the Houfe, conceiving that the circumftances attending his cafe give him a ftrong plea to favour; and that the invention of which he is the author, contains an important improvement in the art of conftructing time-keepers, fuch as the Houfe might well wifh to fecure to the public, as well as to reward the perfon by whom it was produced." Accordingly, in the year 1793, the Houfe of Commons, after the examination of various witneffes, notwithftanding the oppofition of the Board of Longitude, granted to Mr. Mudge, in addition to the 500l. previoufly received by way of encouragement, the further fum of 2500l. under the act of 1774.

We have faid that the felect committee were without a certain rule that would apply in all cafes to afcertain the true rate of a time-keeper at each fucceffive period of trial, a ftandard rate previoufly obtained being in point of accuracy no longer applicable than while the piece conforms to that rate in going. The rule called "Dr. Mafkelyne's method" is this; when the period of obfervation, or trial, continues many months, he takes a mean rate from the going in the *firft month*, and applies it as the ftandard to any fix fucceffive months after, mediate or immediate, which method allows of fix periods in a year of fix months each, or twelve in a year and half; and when a mean rate taken from the firft month was thus applied, whether it was additive or fubtractive, the aggregate amount of the daily errors thus equated, taken on any day of a period, is called *the error* of that day, and the evidences brought againft the going of Mudge's watches were the *greateft error*, and alfo the *mean error*, on an average of the whole period. Mr. Mudge, on the contrary, wifhed the mean rate to be taken on a period of at leaft fix months, as Harrifon's had been on fix weeks, or whole time of trial, and produced as evidence in favour of the going of his watch, the rate taken from a mean of the daily errors during fix months of the trial, and alfo the greateft deviation from that rate on any two fucceffive or remote days, without regarding the aggregate of the daily errors, or what is called *the error* at any particular part of the trial, it being contended that *the error* would never be very great if the rate were properly taken. In confequence of thefe different opinions in refpect to the mode of judging of the performance of a time-keeper, fome of the members put queftions to the witneffes, particularly to Dr. Mafkelyne, tending to afcertain, whether or not a rate could be taken at fea as well as by land? and, on being anfwered in the negative, in what time, on touching at any known point of land, the longitude of which is known, a rate could be obtained? to which the Doctor's reply was "a month:" and his reafon for requiring fo long a time to get a rate, was, that in a voyage only the rates on the firft and laft days can, he fays, be afcertained accurately, but by land the fucceffive daily errors can be compared together, fo that if a fudden change takes place in the rate, the date of that change can thus be afcertained, which he contends is not the cafe on a trial at fea. It would fwell our prefent article too much were we to infert here all the trials in favour of and againft Mudge's time-keepers, and alfo of thofe with which they were contrafted; fuffice it therefore that we refer the reader, who wifhes to know all the particulars, to the "Narrative" publifhed by Mr. Mudge, to Dr. Mafkelyne's "Anfwer to the Narrative," and Mudge's "Reply to the Anfwer." It will fatisfy the ordinary reader, we prefume, to know the annexed particulars refpecting the moft and leaft favourable trials. In the firft trial by Dr. Mafkelyne, made during 15 months; from April 20, 1779, to July 17, 1780, the errors obtained by Dr. Mafkelyne's method of the time-keepers denominated *green* and *blue*, eftimated from eight periods of fix months each, were thefe; viz.

Of *green* the mean error of eight periods was	11′	1″
The greateft - - -	16	25
The leaft - - -	7	20
Of *blue*, the mean error of the fame periods	22	30
The greateft - -	36	26
The leaft - - -	5	53

In

In *green*, the daily error, or rate, was altered at the end of the trial $11^s.3$ which was in excefs.

In *blue* the fame was more in excefs, viz. 18^s.

This trial was the leaft favourable to both time-keepers.

The moft favourable trial of *Green* feems to have been from 21ft July 1783, to 12th Sept. 1784, by Dr. Mafkelyne, in which its mean error on feven periods was $3^m\ 8^s$, the greateft $7^m\ 10^s$, and the leaft $1^m\ 25^s$, the rate at the end having become fafter by 3^s.

But the moft favourable trial of *Blue*, feems to have been its laft under Dr. Mafkelyne in the years 1789 and 1790, in which the leaft error, eftimated on fix periods of fix months each, was $3^m\ 5^s$, and the greateft $6^m\ 0^s$, the acceleration of the rate being at the end $2^s.5$ per day. The proof in favour of Arnold's No. 36 was, that the greateft variation in its daily rate on a trial of 15 months by Dr. Mafkelyne was 7^s; that its greateft error on eleven periods of fix months each, was $2^m\ 31^s$, and its mean error only 54^s. The proof of Mr. Arnold's No. 68 was from a trial of Mr. Everard, of Lynn, in Norfolk, from which it appeared, from 46 periods of fix months each, that the mean error was, according to Dr. Mafkelyne's method, only $2^m\ 33^s$, in only eight of which periods the error exceeded 4^m, and that the greateft variation in its daily rate was 5^s taken on any two parts of its trial. To thefe and other comparative proofs againft Mr. Mudge's time-keepers, the inventor oppofed various trials, as we have before faid, under Doctor Hornfby, Count Bruhl, Admiral Campbell, and Baron (then Doctor) Zach, as well as fome under Mr. Dutton, but as the difference in the daily rates, and not the aggregate, or what is called *the error* is chiefly given as the refult of each trial, we cannot well make a comparifon of refults comprifed in terms of different denominations.

Mr. Mudge junior, previoufly to his father's death, eftablifhed a manufactory for time-keepers, and employed Meffrs. Howells, Pennington, Pendleton, and Colman, to make them for him; fome few of which performed in a way that merited the approbation of certain naval officers of great refpectability, particularly lord Keith Elphinftone, and lord Hugh Seymour, but the difficulty of making the adjuftments fo accurately as Mr. Mudge fen. had done, and the high price put upon them, about 150 guineas each, (which indeed was too fmall, as the younger Mudge was a great lofer by the manufactory) induced the Admiralty to decline giving any other than occafional orders for his majefty's navy; the chronometers of Arnold and Earnfhaw, which were deemed equally good by the Board of Longitude, being fold at an inferior price; though Kendal's price for making a time-keeper after Harrifon's model was 400l. We decline accompanying Mr. Mudge through his complaints againft his opponents, particularly againft Dr. Mafkelyne, whom he has accufed of being too partial to his own darling child, the *lunar method*, to do juftice to any method purely mechanical for anfwering the fame important purpofe; a ferious complaint this, which is corroborated by an affertion, that Meffrs. Harrifon and Arnold fenior, made fimilar complaints: but be this as it may, it is a fact that the younger Mudge has only fold *eleven* time-keepers of his father's conftruction at the time his book was publifhed in 1799, though he had others finifhed, or nearly fo, and that Barraud and Jamefon, as we are informed, made propofals to the Admiralty for finifhing Mudge's time-keepers at the reduced prices of ninety guineas each, though it is well known that they cannot be afforded for this fum. In juftification of the Aftronomer Royal, we will conclude our account of Mudge's time-keeper with the concluding paffages of his own "Anfwer" to the "Narrative;" "the ufefulnefs of the Board of Longitude is too well known to the public, and acknowledged by all but a difappointed artift, to require my pointing out inftances in which they have materially ferved the public and done honour to the nation. Doubtlefs they deferve commendation in another refpect for having been careful concerning the diftribution of the public money. They might indeed have been properly cenfured, if they had given it away to a perfon not legally entitled to it by the act of parliament, or by a partial preference of the lefs deferving perfon to the more deferving ones."

Chronometer by *Meffrs. John Brockbank and Co.* Among other chronometer makers of reputation we have already had occafion to mention the Brockbanks, of No. 6, Cowper's Court, Cornhill, London, fome of whofe chronometers have performed with a degree of accuracy equal to that of perhaps any other maker, though they never applied for any parliamentary remuneration; the original firm of the houfe was Meffrs. John and Miles Brockbank, the former of whom lately died, and the latter is juft gone out of the bufinefs, and is fucceeded by his nephews, Meffrs. John and William Brockbank, fo that the firm is now Meffrs. John Brockbank and Co. On our applying for permiffion to take one of their chronometers to pieces, in order to give a full defcription of all its parts, the requeft was politely and readily granted. *Plate* XV. contains perfpective views of the different portions of the Brockbanks' chronometer, with the exception of the cafe or box, dial-work, face and hands, guard, fpring-ratchet, and fuch other fubordinate parts as are common to an ordinary watch, which may be feen more particularly under the article Watch-work. *Fig.* 1, exhibits the upper plate of the frame, feen a little obliquely, together with the balance, regulating cylindrical fpring, and the three different cocks for holding refpectively the balance verge, upper pivot, the ftud for the outer end of the balance-fpring and the mechanifm for banking. A, B, C, and D, are four circular holes perforated through the plate, juft large enough to receive the ends of the four pillars, denoted by the fame letters in *fig.* 2; E is a hole fomewhat lefs, to receive the end of the fpring-barrel arbor, and is at the place where the ratchet and click are placed to regulate the main-fpring, and preferve its intenfity when regulated: *a* is the compenfation balance, at prefent feen in the form of an ellipfe, as placed on its verge; but in *fig.* 3 is feen in its true fhape of a circle, where the eye is fuppofed to be perpendicularly over it; *b* is the cylindrical balance fpring, with its coils equal in diameter to the radius of the balance, having ufually from four to nine folds, attached at its lower extremity to the balance verge, by means of a collet and pin, and at its upper extremity to a ftud at the extreme end of cock *d*, which is compofed of two parts, fcrewed together by two fcrews, the heads of which appear near *d*; this cock is then fcrewed to the plane of the upper plate by a fingle fcrew, which fcrew, by the aid of two little fteady pins, faft in the cock near the fcrew hole, one of which is reprefented by a diminutive circle, and inferted into fmall holes in the plate, holds the cock firm in its proper fituation; *c* is the principal cock, the end of which has a jewelled hole that receives the upper pivot of the balance, the correfponding pivot is hid, being fupported by the crank part of the potence, which is reprefented by D E F in *fig.* 6, and is fcrewed to the under fide of the upper plate by a fcrew at E, aided by three fteady pins; the pivot hole in this potence is alfo jewelled. The third cock, *e*, is feen on an enlarged fcale in *fig.* 4, where it will be defcribed by and by. The cock, *c*, alfo appears to be compofed of two pieces joined together by two fcrews above the bend, the heads of which appear near *c*, but *c*, but it is in one piece, and theſe ſcrews fix it more firmly to the plate. The fuſee guard, as in common watches, is placed under this upper plate, and is therefore out of ſight.

Take the upper plate from the frame now, by unſcrewing the four ſcrews that go into the ends of the pillars, a contrivance of Meſſrs. Brockbank's, and *fig.* 2 will be preſented to view, in which are contained the main-ſpring, fuſee, and chain, with the mechaniſm of the perpetual ratchet, ſeen ſeparately in *figs.* 7 and 8, the movement of the piece, and the lower or pillar plate with the four pillars, one of which has indeed been purpoſely left out in the drawing, that it might not intercept the view of the movement. A, C, and D, are the three pillars alluded to in our deſcription of *fig.* 1, and B the place in the lower plate, where the fourth pillar ought to be ſcrewed. or riveted, which we have ſaid is left out of the drawing; E is the ſpring barrel, containing a well tempered main-ſpring, ſtronger than the ſpring of an ordinary watch, becauſe the eſcapement is a detached one, requiring the momentary impulſe given to it to be pretty ſtrong; there is nothing particular in the conſtruction of this barrel, except its ſize, which is proportioned to the ſpring it contains; one of which, for a large box chronometer, has been found equal to ſupport a weight of 11 lbs. or upwards; the chain is alſo of the uſual conſtruction, except that it is ſtronger than is neceſſary in a common watch; it is repreſented as partly wound on the fuſee, and partly on the barrel, which is generally the caſe when a watch or chronometer is going, ſo that, in this ſituation, if ſome obſtacle to motion were not preſented to ſome one of the wheels of the train, before the balance is taken out, the piece would run rapidly down, and be in danger of breaking ſome of the pivots or other delicate parts, on which account a briſtle is uſually put through the croſſes of the third or fourth wheel to prevent ſuch accident, while the balance is taken out, a ſmall obſtacle being ſufficient to arreſt the motion when applied near the top of the train, where the maintaining power is diminiſhed in proportion to the number of wheels and pinions in the train that it has paſſed through; the reaſon of which is more particularly explained under our article Clock Movement, where the obſervations we have made are equally applicable to the movement of a clock, chronometer, or ordinary watch. F is the fuſee grooved in ſuch a way, after being made of the ſhape of the fruſtum of a paraboloid, that the decreaſe of the acting radius is always inverſely proportional to the intenſity of the main-ſpring; by which admirable contrivance the effective power of this ſpring is at all times very nearly alike; the adjuſtment of the varying levers, or points of action, of the fuſee, is made very conveniently by a long lever with a moveable weight, like a ſteel-yard, being inſerted on the ſquare of the fuſee arbor made for the key, as will be explained more particularly in its proper place. (See Fusee and Clock-tools.) The number of turns of the fuſee, it has been already ſaid, depends on the number of hours it is intended to be actuated by the ſpring at one winding up, and this number again depends on the ratio between the great wheel and the centre pinion, as has been mentioned in our deſcriptions of Harriſon's and Mudge's time-keepers. The angular point of the cap, at the ſmaller end of the fuſee, near F, is to catch the ſhoulder of the guard, when the chain has filled all the turns of the ſpiral groove; otherwiſe the chain would wind back again a little way, and the power of the main-ſpring would become too great, or perhaps the ſpring might even break by being over ſtrained. Concentric with the fuſee at the large end, contiguous to the pillar plate, are the great wheel, two ratchets, and a ſecondary ſpring to keep the chronometer going while it is wound up; this idea, and alſo the mechaniſm proper for effecting ſuch purpoſe, originated, as we have ſeen, with James Harriſon; but the preſent application of his principle is much more ſimple than his was, inaſmuch as the ſpring is ſo conſtructed, as not to require a barrel or box to contain it. The particulars will be more minutely detailed when we come to *figs.* 7 and 8. In the pocket chronometer before us, the great wheel, which is moveable round the fuſee arbor in one direction only, like that of a common watch, has 60 teeth: *a* is the centre wheel arbor, on which is a pinion of 12 leaves revolving in an hour; this arbor is ſtronger than any other arbor in the train above, not only becauſe more power is impreſſed on its pinion than on any other pinion higher in the train, but alſo becauſe the minute hand is borne by it, and alſo motion given to the hour hand from it; the centre wheel fixed on this arbor has 64 teeth, which impel the pinion of eight leaves on the ſecond arbor *b*; the ſecond wheel of 60 teeth is faſt alſo to this arbor, and impels the third pinion of eight leaves faſt on the third arbor, *c*, which is the arbor for the ſeconds hand, which hand moves in a circle of 60 out of the centre of the face, therefore cannot be miſtaken for the minute hand, which is a matter of ſome importance in a chronometer: on this arbor of the ſeconds hand, a contrate wheel is uſually placed in a common watch, for the ſole purpoſe of altering the direction of motion, that the balance or crown wheel may have an horizontal arbor, but here the caſe is different, the balance wheel, or more properly ſpeaking the eſcapement wheel, has a vertical arbor like the reſt of the train; the third wheel therefore is here like the reſt in poſition, and has 80 teeth driving its pinion of eight on the fourth arbor, *d*, which alſo carries the eſcapement wheel with 15 teeth. From this account of the movement, we now know that the fuſee revolves in $\frac{60}{12}$ of an hour, or in five hours, and alſo that, as there are $6\frac{1}{4}$ turns in it, the whole period of continued motion, at one winding up, will be 32 hours; alſo by our former method of eſtimating the value of a train exemplified in Harriſon's and Mudge's trains; we know that $\frac{64 \times 60 \times 80 \times 15 \times 2}{8 \times 8 \times 8} = \frac{921600}{512} = 18000$ are the number of vibrations in an hour, or five in a ſecond; but as it will be ſeen preſently that there are only half as many audible beats as vibrations in this detached eſcapement in a ſecond, this circumſtance would induce any perſon, not previouſly acquainted with it, to conclude that the train is a lower or ſlower one than is uſed in an ordinary watch, though the reverſe, in point of fact, is the truth. In ſome of the beſt box chronometers, the pinions are 10, and the train = 14400, owing to the large ſize of the balance. At *e* is a ſlender ſpring ſcrewed to the pillar plate, and preſſing againſt the tail of a lever or detent, fixed to the arbor, *f*, and reſting like a click in the inclined teeth of the large or perpetual ratchet, the edge of which ratchet wheel is juſt viſible above the large wheel under the fuſee, but is ſeen better in *fig.* 7; the little ratchet and its click are not ſeen in this 2d figure, but is ſeen alſo within the perpetual one in *fig.* 7.

Fig. 3 repreſents the balance detached from its verge and regulating-ſpring after being taken from its collet on the verge; there are three radial arms meeting and uniting at the centre, which carry each a third part of a circle; this circle is at firſt turned in a lathe out of a ſolid compound plate of ſteel and braſs, a circular plate of ſteel of the required diameter being covered with braſs by immerſion in a crucible of this metal melted previouſly by heat, after which it is divided into three equal portions, which will, by theſe operations, be of ſimilar dimenſions and weight when nicely divided;

divided; this method of uniting the metals, and of forming the balance in a lathe, was the invention of Mr. J. Brockbank senior, though never before publicly known; at the outer end of each of the three radial bars, which are of steel, are three screws of adjustment for time, and also for position, at *a*, *a*, and *a*, where the three portions of the compound circle are supported by their respective radial bars, or sometimes a little at one side. When the chronometer gains considerably, each of these three screws are screwed back or outwards, to increase the momentum of the balance by enlarging its effective dimensions, but the quantity of adjustment must be precisely the same in each of the three screws, supposing the balance previously in equilibrio in all positions. On the contrary, when there is a considerable loss in the rate, the three screws must be alike screwed in a certain quantity, depending on the quantity of the daily error, which a little practice only will determine; but when one of the three screws is screwed in for position, each of the other two must be screwed half the same quantity out, and *vice versâ*, the taps being the same in all. The convex side of the rim of the balance is brass, and the concave side steel; the superior expansibility of the former, therefore, will occasion the remote ends of each of the three expansion pieces, forming the circle, to approach the centre of the balance in high temperatures, by reason of those ends being at liberty, and the opposite ends being fixed to the radial bars; but in cold weather the contrary will be the case; the brass, being more liable to contract with cold, as well as more liable to elongate with heat, than steel, exerts a natural effort, in low temperatures, to straighten the expansion bar, and therefore makes the remote end, in each of the three, recede from the centre of the balance; again, the same heat that makes the remote end of each expansion piece approach the centre of the balance, makes, at the same time, the radial levers elongate, and consequently removes the fixed end of the same expansion pieces from the centre a certain quantity, and *the compensation* consists in a due balance of the two opposite and contemporary motions of the opposite ends of each of the three expansion bars. It is found from experience that the momentum of the balance is best preserved in an equable state by loading each expansion piece with a metallic weight of similar dimensions, and so contrived that they may slide along the expansion pieces, by adjustment, till the exact point is found such in each, that the equipoise of the whole is not destroyed, and yet that the momentum will remain the same in the opposite extremes of temperature, as well as at a medium. The additional weights are denoted by the letters *b*, *b*, and *b*, which have a groove and a screw each, to fix them to the expansion rims. If the additional weights of compensation, *b*, *b*, *b*, were screwed close to the screws of adjustment for rate and position at *a*, *a*, and *a*, it is evident that, as the radial bars are there elongated by heat, these loads would thereby be carried outwards so as to increase the momentum of the balance sufficiently to make the chronometer retard, being an effect similar to that produced by turning the screws *a*, *a*, and *a*, back from the centre; also if the said weights were fixed at the remote ends of the expansion rims, which ends move inwards with the greatest velocity, while their fixed ends are moving but slowly outwards, it is equally evident that, if the weights are too large, which are thus made to approach the centre with the greatest possible velocity, the momentum of the balance will thereby be diminished too much, and the chronometer will have an accelerated rate; there is, consequently, a certain load, which, being fixed in a certain point between the opposite ends of each of the three expansion rims, will render the momentum of the balance least liable to vary in the different degrees of temperature; for if the weight is comparatively small, it must necessarily be fixed near the end at liberty, but if comparatively large, it must necessarily be fixed at some distance from the said end; but until it has been determined in practice, or by experiment, what diameter is best for a given weight of a compensation-balance, with a given escapement and maintaining power, it is not easy to assign the precise quantity of each weight, and the corresponding point in its expansion piece where it ought to be fixed, in order to produce the best practical effect, i. e. the greatest quantum of invariable momentum with the least possible friction and resistance from the air. Various experiments, no doubt, have been tried in the adjustments of the balance, to effect this purpose in the best manner, taking into consideration, moreover, the relative thickness of the brass and steel of the expansion rims; though scarcely any thing has yet been published on the subject; to aid the views of those who are thus laudably employed, we presume to suggest, that the *shapes* of the loading pieces, and of the adjustment screws at present in use, are calculated to meet with too much resistance from the air; and if clock-makers wish to avoid such resistance, by a proper shape given to their balls or bobs in a pendulum, where the momentum is very great, surely the same object is worthy of the notice of the makers of chronometers. Mr. Brockbank once used weights shaped like a double cone, but laid them aside again, supposing it to be a matter of indifference. How far our suggestion may prove useful may be proved experimentally by trying the variation of rate of any machine, small enough to admit of being put under the receiver of an air-pump, whilst it is kept in a complete vacuum, or nearly so; this experiment, however, should not be attempted where there is not a syphon or other gage, to indicate to the eye the state of exhaustion during the trial. A gentleman who tried this experiment, informs us, that the variation in the rate of one of Brockbank's chronometers, was only about one second per day minus.

In the balance before us there is a pin screwed into the remote end of each expansion-piece, exactly opposite to as many projecting pieces of metal borne by the radial arms at *c*, *c*, and *c*, which additions might appear to have something to do with the compensation, but they are only precautionary contrivances, called guard-pieces, to prevent the bending of the expansion-rims too much inward or outward by any jerk or other accidental cause. In the most modern of Messrs. Brockbanks' chronometers, the load of the expansion-pieces is shaped as at *d*, in *fig.* 3, where a third additional screw is put in the direction of a tangent, to adjust for small errors in temperature, where the screws only are moved without the loads, which otherwise might be moved too much, so as to effect more than the desired quantity. *Fig.* 4, is the cock of the banking, marked *e*, in *fig.* 1, but on an enlarged scale; it is screwed down to the plane of the upper plate by the screw A, and kept immoveable by the steady-pin, denoted by a diminutive circle near the screw: B is a small piece of metal borne by a light arm that has a joint, the centre pin of which is seen represented by a dot on the end of the cock near the screw C; this screw is so placed on a side-piece fastened to the cock, that the end of it bears against the side of the joint-piece, and acts as a rest to prevent the joint from opening further than the adjustment requires: D is a very slender straight piece of balance-spring, not blued, with one end in the piece B, and the other in the cock, so that if any slight force is applied on the side of piece B, this piece will have a motion on its centre towards D, but will return to its original position by the force of the flat spring D. E is an erect pin attached to the radial arm, marked *f* in the balance, as exhibited in *fig.* 1, which pin has a triangular head that remains contiguous to the projecting pin in the piece B, and very nearly touches it in the present position in both figures: now the cylindrical spring of the balance may be so adjusted, that the pin E shall be a quarter of a circle, or any given number of degrees, from the piece B, when this spring is in its quiescent state. Suppose it to be a quarter of a circle; and suppose the balance put into a forward motion by any accidental external force; if this force should be great, the balance would revolve, perhaps, two whole revolutions in its circle without any obstacle to stop it, which would overset it, and endanger the teeth of the escapement wheel, which would hobble on irregularly; to avoid such effect, Mr. J. Brockbank sen., having observed that the coils of his spring enlarge their diameters, particularly near the upper end, when wound up by one entire revolution of the balance, ingeniously hit upon the idea of making this protrusion of the coils of his spring subservient to the purpose of limiting the extent of the vibration of his balance, or of constituting the contrivance called the *detached banking*. In an ordinary watch a pin is put into the rim of the balance, which projects sufficiently to prevent its passing two little studs, placed at equal distances from the point of quiescence of the said pin, which studs, therefore, limit the quantity of the whole arc of vibration: this quantity, consequently, when two studs are used, must necessarily be less than a circle, even if the common escapement would admit of such a long vibration; and if one stud only were placed just a semicircle each way from the pin's quiescent point, the limit would then be an exact circle, after deducting the thickness of the stud; but in a chronometer one entire vibration generally exceeds a circle, when the piece is clean; a circumstance which constitutes one of its excellencies, by augmenting its momentum; hence the contrivance wanted was to allow the balance to vibrate more than an entire circle, and then to stop it at a given part of the second revolution: to effect this purpose, the late Mr. J. Brockbank invented the mechanism already described in *fig.* 4, which acts thus; when the balance first begins to vibrate, the coils of the spring do not alter their shape, and the pin E of the balance passes the piece B attached to the cock untouched, the position of B not having been altered by any external force; but when the balance comes round a second time, the protrusion of the coils becomes great enough to strike against the piece B, placed near the spring; it now yields to the impulse of the protruding part of the spring, and moves towards D, taking its pin along with it; and in this new situation it is that the pin of B is presented to the head of the pin E, carried by the balance, and acts as a banking-stud to prevent the further vibration, or, perhaps, we should say rotation, of the balance; in the contrary motion of the balance it cannot be overturned, by reason of the locking-spring not being moved by the backward motion of the lifting pallet. The contrivance before us is certainly an ingenious one, and, we understand, answers its intended purpose very well. The weight of the pin E is, of course, counterpoised in the adjustment for position.

Figs. 5 and 6 represent the escapement-wheel, pallets, and springs used in the business of alternately locking and unlocking the teeth of the pallet-wheel, on an enlarged scale, and as they would be seen by an eye placed over the principal cock, if the upper plate were transparent; but they are hid by this plate in *fig.* 1; the wheel, however, may be seen on its arbor projected on the fusee in *fig.* 2, and the pallets may easily be conceived to be put under the upper plate, through an aperture in the plate, and to be attached to the lower part of the balance-verge above the lower pivot, which pivot, we have said, rests on the crank part of the potence DEF, beneath the said plate, which potence is also supposed transparent. The shorter, or inner slope of the tooth is directed, not to the centre of the wheel, but to a point in the radius, about $\frac{1}{4}$ from the centre, which mode of shaping is called under-cutting. The same letters of reference apply to both the *figs.* 5 and 6, in which A is the escapement-wheel of 15 teeth, (but of 13 in a box-chronometer,) and B the large pallet of polished steel, first made circular, but afterwards notched, to make way for the teeth in passing, and to receive a piece of finely polished diamond, *c*, at that part of the notch where the end of tooth 1 nearly touches it in *fig.* 5; the little dotted piece *d*, like a bird's head, placed on the balance-verge, concentric with the large pallet, but below it, so as to be covered by it, is the lifting or unlocking-pallet made of steel, set with sapphire: C is a long slender spring, screwed to the under side of the upper plate, carrying a protuberance, *a*, called the locking-pallet, and embracing at its loose end, by a semicircular bend, the verge of the balance, the bent part of which, being hid under the large pallet B, is represented by a curve line of double dots: D is another very slender spring fixed by a pin at *c* into a hole in the end of the bar *c d*, which is elastic, and screwed to the potence at *d*; the screw *c* is tapped into a stud in the potence, and bears against the bar *c d*, and adjusts the length of D, which reaches a little beyond the curved end of the locking-spring, called also sometimes the detent-spring; this slender spring D is denominated the unlocking-spring, because the lifting or unlocking-pallet, hitting it on the end, drives it against the crooked end of the locking-spring, and thereby forcing the pallet *a* from a tooth of the wheel, unlocks the wheel and leaves it under the controul of the maintaining power; lastly, *b* is a screw, which, supported by a little tapped cock, constitutes a rest for the detent-spring, when it has returned, in consequence of its elasticity, from the situation it was driven to by the lifting pallet. The two slender springs C and D point in the same straight line through the centre of the balance-verge; and the action of the escapement-mechanism is this: suppose the balance to be at rest in the first place, and the respective positions of the parts as in *fig.* 6, the circular side of the large pallet nearly in contact with tooth 1, and the tooth preceding it; the lifting pallet must be as in *fig.* 5, a little short of the end of the unlocking-spring D, and tooth 2 resting on the locking pallet *a*; while every thing remains in this state, the maintaining power is suspended by the tooth 2 being detained by the locking-pallet *a*, and the machine will not have power to put itself into motion; but let some external force be applied to put the balance in motion, by turning the chronometer suddenly round horizontally, or otherwise, and, supposing the motion impressed to be in a direction from B towards the lifting-spring D, the angular point of the lifting-pallet, moving along with the balance and large pallet B, strikes the extreme end of the locking-spring D, and drives it, and also the bent end of the locking-spring C, against which the other rests, far enough to disengage the locking-pallet *a* from tooth 2 of the escapement-wheel; which wheel, therefore, instantly runs on by the impulse through the train, in a direction towards *b*; but in the mean time the sapphire face of the pallet, moving with the balance, has got before tooth 1; this tooth, therefore, now strikes the said face of the large pallet and urges it on, we will suppose, till it arrives at the line joining the centre of the wheel and great pallet, as is represented in *fig.* 5; in this situation, it will be seen, the lifting-pallet has quitted the end of the lifting or unlocking-spring, and the

the locking-pallet *a* is about the mid-way between tooth 2 and tooth 3: during the continuance of this portion of the wheel's impulfe on the face of the large pallet, the extreme end of tooth 1 has flided forwards along the plane of the pallet's face, which we have faid is fapphire, and, therefore, produces but little friction; but now, as the tooth 1 advances in its revolution beyond the line joining the centres of the wheel and large pallet, it proportionably returns along the face of the fapphire, till, at length, it completely efcapes the pallet, in which fituation it would run on violently, but by this time the locking-fpring has returned to the end of fcrew *b*, and has prefented its locking-pallet to receive tooth 3, which has juft arrived at this pallet, when tooth 1 drops from the large pallet; the train, confequently, is again detained, and the balance proceeds in its vibration, together with the large and lifting pallets, in a ftate completely detached from every obftacle, except the balance-fpring, which fpring, by being wound up, oppofes its free motion, and, at length ftops it; the ftation, however, is but of fhort duration, as the balance-fpring conftantly exerts its power to bring back again the balance; it returns; the back or curved part of the lifting-pallet ftrikes the end of the lifting fpring D at the inner fide, which being very flender gives way, and the locking fpring, not being difturbed, remains in *ftatu quo*. The returning force of the flight fpring, D, is exhaufted at the inftant of its arrival at its point of former quiefcence, and the balance proceeds in its retrograde vibration, by the accelerated force it has acquired on its arrival at this quiefcent point, until the oppofition of its fpring renders it again ftationary for an imperceptible moment, after which the original procefs, which has been defcribed, is refumed, and an alternation of backward and forward vibrations is perpetuated by means of one little impulfe, given by each fucceffive tooth of the wheel, as long as the maintaining power continues in a ftate of fufficient intenfity. With a given maintaining power and a given efcapement-wheel, the momentary impulfe given to the balance, in any chronometer of this conftruction, has its intenfity meafured directly by the effective length of the large pallet, in any fituation of the acting tooth; whence the intenfity of the impulfe would be a minimum in the fituation exhibited in *fig*. 5, in a point lying in the line of the centres, if this fituation were not the moft favourable to the tranfmiffion of the impulfe; but as the wheel here impels the pallet in the direction of a tangent from its point of action, and as this tangent is alfo perpendicular to the face of the pallet, the effect on the balance is here the greateft, independently of the force from the accelerated velocity. The lifting-pallet makes its ftroke at that part of the balance's vibration, when it has come within 20° of its original point of quiefcence, and as the fcale of forces may be confidered as changing foon after this point from an increafing to a decreafing one, there will here be very little difturbance produced in that fcale; befides, the continuance of the faid ftroke will be fmall as well as its force great by being near the point where the velocity is a maximum.

Again, in any chronometer of this conftruction, the arc of continuance of the wheel's action on the great pallet is inverfely proportional to the diameter of it, compared with that of the efcapement-wheel; therefore the larger the pallet the fmaller is the arc of action, and *vice verfâ*; but then, we have faid, that the impulfe is proportionably larger or more intenfe; it is probable, therefore, that there is a medium between a large impulfe given in a fmall arc of action and a fmall impulfe continuing during a larger arc of action, which medium may produce an effect moft fteady and moft in concert with the varying fcale of momentum in the different parts of the total vibration. Mr. Earnfhaw has laid much ftrefs on the circumftance of his large pallet being of half the diameter of the efcapement-wheel; but the inference does not appear to have been the refult of any nice calculations or varied experiments of his; for before him his mafter, the fenior Mr. Brockbank, ufed a pallet in his pocket chronometer, exactly fimilar, though it was a trifle lefs in his box one: but Mr. Arnold's large pallet, in general, is much fmaller, though fome of his chronometers have had as large pallets as thofe of either of the other two. Mr. Miles Brockbank informs us, that his brother and he found from experience, that a fmall pallet does not produce fo large a vibration as a large one with the fame maintaining power.

Fig. 7 exhibits a view of the great wheel, and two ratchets with their clicks fitted to the large end of the fufee, and conftituting, with it, what is called the *going fufee*; the conftruction is more fimple than that of Harrifon's, which we endeavoured to defcribe without a drawing, and anfwers its purpofe equally well. The ratchet, *a*, or fmall ratchet, is fixed by two fcrews or pins to an excavation in the large end of the fufee, the central part being left perforated for the fufee-arbor to pafs through, and its plane lying in the plane of the end of the fufee; its click and fpring, *b*, are fcrewed to the plane of the large or perpetual ratchet, *c*, which has its teeth inclined in a direction contrary to thofe of the fmall ratchet, *a*, and are bedded in a groove turned in the end of the fufee, between the fmall ratchet and great wheel; we have fhewn but one click for the fmall ratchet, but generally there are two, one at each fide of it; the click-fpring of the perpetual ratchet is fcrewed to the upper plane of the pillar plate, as feen at *e* in *fig*. 2, where it will be feen that the click turns on an arbor, and acts as a detent; *e* (*fig*. 7.) is the great wheel, and *fig*. 8 is a horfe-fhoe fpring, bedded between the perpetual ratchet and the great wheel, a circular groove being turned in the plane of the large wheel, or it might be in that of the large ratchet, or partially in both, to form a bed for this fecondary fpring; the pin, *a*, at one end of the fpring, is inferted into a correfponding hole in the bed of the wheel, and the other pin, *b*, into a fimilar hole perforated through the perpetual ratchet at *f*; this fpring, thus connected with both the great wheel and perpetual ratchet, would produce no other effect than to attach them together, and make them like one wheel, if the horfe-fhoe piece were not elaftic, in which cafe the large ratchet would be fuperfluous, and the effect produced would be that of an ordinary fimple ratchet; but the piece in *fig*. 8 is of a fpring temper, and its elafticity fmall enough to be acted upon by the main-fpring, fo as to make the two pins, *a* and *b*, at the ends approach each other; and in this fituation it is that the fecondary fpring is faid to be wound up, and in which it continues whenever the chronometer is going. When the key is applied to the fufee-arbor to wind up the piece, the click, *b*, will flide over the ferrated teeth of the fmall ratchet, *a*, which revolves with the fufee, and the large ratchet, *c*, would alfo revolve a little way with it, to let down the intenfity of the fecondary-fpring, which now exerts its force to remove its ends apart from each other to their natural ftate as they are feen in *fig*. 8.; but the click or detent, held to its teeth by the fpring *d*, prevents this little motion from *b* towards *a*, which otherwife would have taken place from the pulling of the pin *b* inferted into its little hole; in confequence of this oppofition to the great ratchet's temporary motion by the action of its detent, the pin, *a*, at the other end of the fecondary-fpring pulls at its hole in the great wheel, and draws it towards *b*, or, in other words, draws the great wheel round in a contrary direction, and with a force equal for a time to that of the original maintaining power by which the two pins were made to approach each other. The reafon of pin *b*, in *fig*. 8, being made to project both ways acrofs the end of the fecondary

condary ſpring, is, that the remote end beyond b may move in a circular little aperture made through the plane of the great wheel behind f in *fig.* 7, which aperture allows the two ends of the ſpring to approach and recede ſteadily, and the length of the aperture is determined by the quantity that pin b is drawn by the main-ſpring towards pin a before there is an equipoiſe in their intenſities.

Some years ago Mr. Ed. Troughton contrived a jambol or gimbol for preſerving the horizontal poſition of a pocket chronometer at ſea, which is loaded with a weight, turning on the point of a pin, like the card of a compaſs, and continues to be made by Meſſrs. Brockbank and Co. with conſiderable advantage to the going of the chronometer. The order of the adjuſtments is this: firſt the adjuſtment for temperature is made in heat of from 90° to 120° of Fahrenheit, and alſo in as great a degree of cold as can be obtained; ſecondly, the chronometer is cleaned anew, and has freſh oil put on; thirdly, the adjuſtment for rate and poſitions is made; and, laſtly, the rate is taken. There are, beſides the three pallet-faces of ſapphire, eight jewelled holes in the beſt chronometers; viz. two at the balance verge pivots in the cock and potence, two at the pivots of the eſcapement-wheel, and two for each of the two next wheel pivots, called the fourth and third wheels of the movement, beginning with the great wheel as firſt, but the third and ſecond of the train, if we count from the centre or hour-wheel. The pivots are tapering, in the form of a cone, and bear on their ends in action, which ſhape gives ſtrength, without adding to the friction.

It cannot be expected that the beſt chronometers will ever be manufactured at ſo low a price as watches without the compenſation and detached eſcapement; but when, as many different hands are employed in making their ſeveral parts, as are employed in the making and finiſhing of an ordinary watch, we may expect that the price will be proportionably reduced; the loweſt price that we have been informed of, as the price of any good maker for a pocket chronometer, is forty guineas, but in general they cannot be afforded for ſo little when all the adjuſtments are well made, which take up much time as well as patience. At preſent the *movement*, that is, the frame containing the barrel, fuſee, wheels, and pinions, all but the eſcapement-wheel, is made, like the movement of a watch, by the different workmen employed for this purpoſe in Lancaſhire; the motion or dial-work is next added by a workman in London, who has the main-ſpring, chain, face, and hands, from the reſpective makers in town; then the eſcapement-maker and the jeweller are employed to finiſh their departments; and, laſtly, the *maker*, as he is called, finiſhes the adjuſtments, and puts the works into the box, or caſe, or both, as may be required. In the progreſs of theſe different ſtages, or even after the adjuſtments are begun, it is frequently neceſſary to alter, and many times to change certain parts, as the ſprings, compenſation-rims, adjuſtable weights, &c. which neceſſarily enhance the price the chronometer might otherwiſe be afforded for.

The teſtimonies, both public and private, of the accuracy of ſome of Meſſrs. Brockbanks' chronometers in meaſuring time, are ſufficiently numerous to eſtabliſh their credit. Several letters from naval officers and rates were delivered to the Board of Longitude during the time of Mr. Earnſhaw's application for remuneration, which cannot be reſtored without an order from the Board; otherwiſe it would have been in our power to have laid ſome of them before the public. Governor Hunter, in his publication, has given a teſtimony ſo extraordinary, that we cannot, in juſtice, with-hold it; he has aſſerted, that, from the time of his ſetting out from Port Jackſon in New Holland, on a twelve months voyage round a great part of the globe, in the courſe of which he remained ſome time at the Cape of Good Hope, to the time of his return to the ſame port, a time-keeper or chronometer by the Brockbanks was found to have gone ſo well, that the error, at the end of the voyage, did not exceed *one ſecond* of time. This, however, will be conſidered rather as an extraordinary coincidence of the ſtate of the watch at the beginning and end of the voyage, than as a proof that its accuracy was thus great at all the intermediate parts of the voyage. Mr. Gavin Lowe, of Iſlington, has a pocket chronometer, the rate of which was given to Sir Joſeph Banks to be laid before the Board of Longitude, which, we have heard, exceeds, in accuracy, the rate of any other pocket chronometer that has been made, inaſmuch as that the rate in it is not ſenſibly affected by cleaning in the courſe of many years wear. But, as we have ſaid, it is not our intention to preſs upon the public attention the merits of any individual maker excluſively, we ſhall ſatisfy ourſelves with copying only one additional teſtimony in favour of our preſent maker, from the report of lord Hugh Seymour, who tried three of Mr. Mudge's time-keepers againſt one of Mr. Earnſhaw's and one of Meſſrs. Brockbanks' chronometers, in a cruiſe from the 18th of May, 1796, to the 19th of Auguſt following.—The report was this: viz.

"At noon, May 31ſt, the town of St. Mary, on the iſland of that name, bore N. 10° W. diſtance 30 miles. The longitude of the ſhip, at that time, taken from the requiſite tables and corrected by the above bearings, gave 25° 3′ 15″ W. Mr. Mudge's watch, called No. 4, gave 1′ 45″ W. Mr. Mudge's watch, called *green*, gave 1′ 45″ E. Mr. Mudge's watch, called *blue*, gave 9′ 15″ E. Theſe watches were taken from the academy at Portſmouth, May 10. A watch made by Mr. Earnſhaw gave 3′ 45″ W. and one made by Mr. Brockbank gave 15′ 45″ E. of the ſhip's place. The mean of all gave 4′ 18″ E. Theſe two laſt watches were too ſhort a time on board at Spithead to obtain their rate exactly, *but were given a new rate this day.*

"At noon, June 4th, the town of Delgada, on the iſland of St. Michael's, bore N. 5 miles. The ſhip in the longitude of 25° 42′ W. No. 4 at that time gave 11′ 15″ W.; *green*, 5′ W.; *blue*, 5′ E.; Earnſhaw, 2′ 15″ E.; and Brockbank, 1′ 45″ E. The mean of all 1′ 30″ W. of the ſhip's place.

"At noon, July 16th, Cape St. Vincent bore N. 81° E. 4 miles. The ſhip in the longitude of 9° 7′ W. No. 4 at that time gave 3′ 15″ E.; *green*, 10′ 30″ W.; *blue*, 13′ 30″ E.; Earnſhaw, 16′ 30″ W.; and Brockbank, 2′ E. The mean of all 1′ 39″ W. of the ſhip's place.

"At four in the afternoon, Auguſt 12th, the light-houſe of St. Agnes was ſeen bearing N. diſtance 19 miles. The longitude of the ſhip at that time was 6° 28′ W. and ſuppoſing Scilly to be in *that* longitude. No. 4 gave 27′ 30″ E.; *green*, 8′ 30″ W.; *blue*, 18′ 15″ E.; Earnſhaw, 56′ 30″ W.; and Brockbank, 6′ 15″ E. The mean of all 2′ 30″ W. of the ſhip's place.

"At noon, Auguſt 13th, the Start bearing N. 28° E. diſtance 19 miles: the longitude of the ſhip was 4° 5′ 15″ W. No. 4 at that time gave 28′ 15″ E.; *green* 9′ 15″ W.; *blue* 17′ 15″ E.; Earnſhaw 59′ 15″ W. and Brockbank 6′ 45″ E. The mean of all 3′ 9″ W. of the ſhip's place.

"At Spithead, Auguſt 18th, the ſhip in the longitude of 1° 7′ 20″ W. No. 4 gave 30′ 20″ E.; *green*, 12′ 10″ W.; *blue*, 15′ 50″ E.; Earnſhaw, 1° 11′ 10″ W.; and Brockbank, 7′ 20″ E. The mean of all, 5′ 55″ W. of the truth."

From this report it is evident, that, after a proper rate was aſſigned, Meſſrs. Brockbanks' chronometer performed with a degree of accuracy which far exceeded any one of the other four, indeed, we may ſay, which has ſeldom been equalled by any other chronometer.

 After

After being apprifed of thefe and other teftimonies, we inquired why the Brockbanks never applied to parliament for a public trial of any of their chronometers, with a view of obtaining the premium under the act of Geo. III., and received for information, that, after having been refufed a private trial at the Royal Obfervatory, and on finding that much trouble was likely to attend the application to the Board and fubfequent public trials, the idea at one time entertained was given up; which circumftance is our reafon for having troubled the reader with lord Hugh Seymour's report at full length.

CHRONOMETER by *Mr. Arnold.* After the minute defcription of all the parts of Meffrs. Brockbanks' chronometer, it would be fuperfluous to repeat here an account of fuch parts as are common in all the modern chronometers; we therefore propofe to omit the drawings of the movement and other portions of the mechanifm contained within the frame of both Mr. Arnold's and Mr. Earnfhaw's chronometers, and beg leave to refer thofe readers who wifh to fee all the individual portions of each of thefe two, to a pamphlet lately publifhed by the Hon. Commiffioners of Longitude, which is charged five fhillings, and in which are contained three plates of each author, together with the defcriptions of the plates, and the queftions put by the Board of Longitude relative to each conftruction, together with the anfwers. This pamphlet is entitled, "Explanations of Time-keepers conftructed by Mr. Thomas Earnfhaw, and the late Mr. John Arnold," Payne and Mackinlay, Strand, 1806. The movements are made with pinions of 8 or 10, according as they are intended for pocket or box-chronometers, to which the correfponding wheels for trains of 14,400 or 18,000, may be had by infpection in our tables under our article CLOCK-MOVEMENT, calculated on purpofe for the workmen who are movement-makers, and who chiefly refide in Lancafhire. It may be neceffary to mention, that Mr. Arnold's box-chronometers have very ftrong main-fprings requiring a deeper barrel than is neceffary for the length of the frame pillars, on which account there is a cap fixed on the plane of the upper plate, to receive the lower pivot of the barrel arbor, and to hold the click and click-fpring of the ftrong ratchet, as placed on the fquare of this projecting arbor; but there is no occafion for fuch addition in the pocket-chronometer. The efcapement-wheel A, fhown in *fig.* 1, of *Plate* XIV. of *Horology*, is Mr. Arnold's, on an enlarged fcale, and, like Meffrs. Brockbanks', is placed near the lower end of its arbor, within the frame, fo as to have only a fmall portion of it feen by an eye placed over the cock, when the piece has its natural pofition reverfed: this wheel is what is called a *funk* one; that is, it has its teeth, like thofe of a cylinder-efcapement-wheel in this refpect, projecting from the plane of the wheel, as feen in *fig.* 2, which reprefents a fide-view of the fame wheel. The fhape alfo of the teeth of the wheel before us differs from that of Meffrs. Brockbanks' and Mr. Earnfhaw's in another refpect: the triangular acting part of each tooth, which is raifed from the plane of the wheel, is bounded by two ftraight lines and a curve; the curved portion, which acts with the jewelled face of the large pallet B, and which Mr. Arnold jun. in his defcription calls a *cycloidal curve*, is defcribed as being generated by the revolution of a fmall circular piece of metal with a tracing-pin in its circumference, while it rolls on the circumference of a larger metallic circle, as a bafe, and is, therefore, properly fpeaking, *epicycloidal*; a cycloid being generated by a circle rolling on a ftraight line: the proportions of the generating circle, and its bafe are ftated to be as the diameter of the large pallet to that of the efcapement-wheel; but, by confulting what we have faid on the proper fhape of acting teeth in an impelling-wheel in our article CLOCK-MOVEMENT, the reader, we prefume, will agree with us, that, to have as little friction as poffible, the fmall circle with the tracing-point, called the generating circle, ought to be equal to the *radius*, not the *diameter*, of the large pallet; which pallet may properly be confidered as a pinion for the fhort time it is impelled by a tooth of the efcapement-wheel; in the fame place, above referred to, it will be feen, indeed, that the difference of the curves, generated by a tracing-piece equal to the diameter, and by a tracing-piece equal to the radius of the fame wheel or pinion, will fcarcely be fenfible till the two curves have been carried on farther than is neceffary for forming a fmall tooth; fo that the diftinction in theory makes no confiderable difference in practice, which we here mention, left an unfavourable opinion fhould be entertained of the teeth in queftion: but, what may feem to fome of our readers a curious circumftance, when the epicycloidal tooth in any wheel is formed by a generating circle of double the fize it ought to be from theory, the friction of the parts in wear will ultimately produce the curve that ought to have been originally formed by a generating circle of a due fize, provided the tooth of the wheel acting with it is of a proper fhape, and of a more durable metal; becaufe, when the teeth of any two wheels that act together are both formed truly from proper generating circles rolling on proper bafes, thefe teeth will roll over one another without, or nearly without friction, and preferve their original figure unimpaired; but if one of the two fhall happen not to have the exact curve, the friction in the action will wear away the fuperfluity of fubftance beyond what ought to have been there to conftitute the true curve; and as a large generating circle gives a fuller tooth than a fmall one, there will neceffarily be that fuperfluity in its fize which we have fuppofed to exift, when the diameter is ufed for radius in the generating circle. Thus a flight deviation from the true epicycloidal fhape of the tooth of any wheel will be rectified by its action with a lefs deftructible body of an exact fhape for true action, and it will be feen, under the article to which we have already referred, that a *ftraight line*, the particular fhape of the jewelled face of the large pallet, is one of the varieties of an interior epicycloid generated by any generating circle revolving on the concave fide of a circle of *twice its diameter* ufed as a bafe of generation.

We made thefe obfervations under an impreffion that Mr. Arnold's tooth *rolls* over the furface of the face of the pallet during the time of its impulfion, in which cafe the friction and deftruction of the parts of contact would have been the *leaft poffible*; but on examining his drawing more minutely, and on adverting to the queftions put to Mr. Arnold, junior, by the Board of Longitude, we find that the tooth of the wheel always continues to act at the extreme point of the pallet's face, over which angular point, probably rounded a little, the curved part of the tooth *flides* inftead of rolling, by reafon of every acting part of the tooth coming in fucceffion to the fame point of the pallet. This mode of action does certainly require that the ratio between the generating circle and its bafe fhould be exactly as ftated by Mr. Arnold; it being that particular cafe where a wheel drives a lantern pinion with fmall fpindles, as may be feen by the reference we have more than once given to CLOCK-MOVEMENT. However, we are ftill perfuaded, that to give an impulfe to the large pallet without friction, would be more defirable than the method before us, if it is equally practicable. An adoption of the mode we have propofed would, we think, on mature confideration, require either the wheel to have more teeth than has been uſual, or the pallet to be larger, to which we ſee no objection, as the arc of action would in either caſe be diminiſhed.

"The ſize of the pallet depends upon the number of teeth in the eſcapement wheel, ſays Mr. Arnold, in his Deſcription of his father's eſcapement. The radius of the pallet ſhould be equal to the diſtance between any two teeth of the wheel, and then their relative motions will be equal. If the wheel has twelve teeth, the radius of the pallet will be thirty degrees, meaſured on the circumference of the wheel, and its diameter ſixty degrees (nearly), meaſured in the ſame manner, which will make it half the ſize of the wheel. If it has thirteen teeth, the pallet will, in diameter, meaſure fifty-five degrees and a half; if fourteen teeth, fifty-one degrees and a half; and if fifteen teeth, which is the number generally applied to pocket time-keepers, it will be forty-eight degrees. The marine (or box) time-keeper is made to beat half-ſeconds, the balance making 240 vibrations both ways in a minute; for if the balance-wheel has 15 teeth, the fourth wheel 80 teeth, and the balance pinion 10 teeth, there will be 120 beats, or half ſeconds, in one minute. It is alſo made with the eſcapement wheel of 12 teeth, the balance pinion having 7, and the fourth wheel 70 (counting from the great wheel); conſequently there will be 120 beats or half ſeconds in one minute, as before. It has been already remarked that the pallet for 12 teeth muſt be half the diameter of the wheel, and for 15 teeth five-twelfths, or fifty degrees.

"The pocket time-keepers, that they may not be diſturbed by motion, have what is called a quicker train, the ſeconds hand making 150 beats upon the dial, or 5 beats in two ſeconds. The eſcapement wheel has 15 teeth, the balance pinion 8 teeth, and the fourth wheel 80; conſequently there will be 150 beats in one minute, the pallet being 50 degrees in diameter, meaſured upon the diameter [ought to be circumference] of the balance-wheel. No mention has been made of the numbers of the teeth in the other wheels and pinions, as they are of little or no importance, and may be varied conſiderably."

We beg leave to differ here from Mr. Arnold, being decidedly of opinion that pinions of 6, 7, and even 8, are by no means ſo well calculated to tranſmit the maintaining power equally, as pinions of 10 and upwards; indeed Camus has demonſtrated in his chapter on the proper ſhape of teeth of "*Cours de Mathematique*," lately tranſlated into Engliſh, that no ſtrong pinion with a number of teeth under 10 will act with a wheel of ordinary ſize, entirely on one ſide of the line joining the centres of the acting wheel and pinion; therefore will not act without much friction; beſides, the more numerous the teeth are in a given wheel, provided the ſtrength of the tooth be ſufficient for its purpoſe, the leſs the teeth take into thoſe of the pinion, and conſequently the leſs the friction, in this ſecond point of view; if pinions of 12 or upwards were to be adopted in watch-movements and clock-movements, the advantage accruing from the adoption would be conſiderable, provided the weight of the wheels, towards the third and fourth wheels, were as little as their requiſite ſtrength will admit.

Mr. Arnold has given four poſitions of his eſcapement wheel in *Plate* III. of his deſcription, delivered to the Board of Longitude; figure one ſhows the wheel locked, and the balance returning in a detached ſtate from its ſecond excurſion; the ſecond figure ſhows the ſituation of the three pallets at the inſtant of unlocking; the third, which is our *fig.* 1, of *Plate* XIV., ſhows the ſituation of the different parts when the impulſe is half given, the jewelled face of the large pallet being in the line that joins the centres of the eſcapement wheel and pallet; and his figure four exhibits the parts at the moment when the impulſe ceaſes to be given by the acting tooth of the wheel. After what we have ſaid of the mode of acting in Meſſrs. Brockbanks' eſcapement, it will eaſily be apprehended what thoſe relative poſitions are from a verbal deſcription; particularly as we have put the ſame letters to the correſponding parts of both eſcapements, to aſſiſt the reader in comparing what we have before ſaid with our preſent deſcription. A is the eſcapement-wheel of Mr. Arnold's marine or box chronometer, made of braſs, and having 12 teeth, with their triangular ends projecting upwards, or rather downwards, when the face is up, from the plane of the wheel; B is the large impelling pallet of ſteel, at firſt made circular, like Meſſrs. Brockbanks', but having its notch terminated by two ſtraight lines pointing to its arbor, in one of which its jewel *c* is fixed; C is the locking ſpring, ſcrewed at its remote end to the under ſurface of the upper plate, and playing in a notch, or ſtraight groove made in the plane of the plate to receive it; its weakeſt part is about C, or between C and the fixing ſcrew, about which point it may be ſaid to turn as on a centre, but having no pivot, it requires no oil; about the middle of this ſpring, C, is a ſecond weaker ſpring, D, attached to it, which, in Meſſrs. Brockbanks', is a detached ſpring lying at the oppoſite ſide of the great pallet, and pointing to its centre; the end of this ſlender ſpring, which is called the unlocking ſpring, comes nearer towards the centre of the large pallet than the ſame end of the ſpring C; the ſaid two ſprings, thus attached together, have a great reſemblance, as they are ſeen in the figure, to a metallic pen in a pocket caſe of inſtruments, when one of the nibs is longer than the other; nearly at one third of the ſpring C, from this interior end, and on the ſide next to the wheel at *a*, is the locking pallet, the acting portion of which is a jewel; this jewelled pallet reſts againſt the heel of the tooth, or neareſt angular point towards the centre of the wheel, and in the act of unlocking is driven *inwards*, to allow the projecting portion to move *behind* it, when the wheel is unlocked; but, leſt the locking ſpring ſhould yield to the preſſure of the wheel when locked at any time, a ſcrew *b*, tapped into a ſtud in the upper plate oppoſite the pallet, *a*, bears againſt the exterior ſide of the locking ſpring, to prevent its falling back beyond a certain limit. In the drawing, the pallet appears to be a continuation of the ſcrew through the ſpring, on account of being placed over, or very nearly over it: the centre of motion of the unlocking ſpring, D, is near the ſcrew we have juſt deſcribed, from which it is free, by being narrower than the locking ſpring, C, and conſequently alſo weaker, when equally thin; the unlocking ſpring, D, therefore, is at liberty to move back towards the ſcrew-head without affecting the poſition of the locking ſpring, C, but when, by an impulſe received, it moves in a contrary direction, it muſt neceſſarily take the locking ſpring along with it, and conſequently the pallet, *a*, attached to this locking ſpring alſo. The lifting, or unlocking pallet in Mr. Arnold's conſtruction, is a ſtraight piece of ſteel, *d*, carrying a jewel, pointing not in a direction nearly oppoſite to the face of the large pallet, as is the caſe in Meſſrs. Brockbanks', but in one vibration follows the face of the large pallet a very little, and in the other precedes it as much: if two lines were drawn along the acting faces of theſe two pallets, which are fixed by friction on the verge of the balance, the angle contained would be very ſmall in the figures given by Mr. Arnold, in conſequence of his locking on the ſecond tooth, but we have not exact data whereby to calculate it, as will be ſeen more particularly in our account of Mr. Earnſhaw's chronometer, which

which follows, becaufe we are not informed by Mr. Arnold where the unlocking pallet refts when the regulating fpring of his balance remains quiefcent. Meffrs. Brockbanks' efcapement wheel, like Mr. Arnold's, locks, as we have feen, at the neareft tooth behind the face of the large pallet, whereas Mr. Earnfhaw locks at the third, counting the tooth of action one, as will be feen by and by; but, unlike all the others that we have feen, Mr. Arnold's locking fpring receives an impulfe *inwards*, to ftrike the locking pallet from the tooth of its wheel: we pretend not to affert, from theory, that this kind of action is either more or lefs favourable to the efcapement than when the locking pallet is driven *outwards*; in either cafe, if the face of the tooth is fuch, that the efcapement wheel has no recoil during the difengagement, the total refiftance will be nearly fimilar; for though that part of the tooth, which is neareft the arbor of the wheel, preffes on the pallet more than the extreme points would do of the *fame wheel*, under the fame circumftances, in confequence of which, the preffure is here greater near the termination of the impulfe given to the locking pallet than at its beginning, yet we do not conceive this to be any difadvantage, becaufe the locking pallet may thus be fuppofed to be unlocked gradually, rather than by a fudden jerk, which muft be partly the cafe, when the preffure of the wheel's tooth againft the pallet is a maximum at the commencement of the impulfe that detaches the locking pallet. When, however, a comparifon of this kind is made between two efcapement wheels, we ought to take into the account their relative diameters, the relative maintaining powers as exerted at thefe wheels, the relative ftrengths of the regulating fprings, as well as of the locking fprings, and alfo the relative points in the arcs of vibration where the unlocking pallets ftrike, compared with the relative points of quiefcence of the balance fprings; all of which are data, involving a complexity of calculations not entered into, we prefume, by the chronometer maker, when he feels difpofed to prefer one conftruction to another, on views more fuperficial.

We have already faid, that in our *fig.* 1., the wheel is at the middle point of its arc of action, confequently, the lifting pallet *d* has let go the contiguous end of the unlocking fpring D, and the pallet *a* has returned to the fcrew point, to be ready to receive the next following tooth 3.; the direction of motion being fuch, that the teeth, 1, 2, 3, &c. follow one another in fucceffion. In this fituation, it appears to us, that the heel of tooth 2, which is now moving, is too near the pallet *a* in the figure; for, when the other half of the impulfe has been given, and the tooth 1 has efcaped the pallet, the tooth 3, which is now nearly two-thirds of a fpace from the pallet *a*, will have one-third drop before it arrives at it, which muft be prejudicial to the fteady motion of the balance. It is eafy to fee, that, during this vibration of the balance from D towards *c*, the unlocking pallet *d* muft have hit the projecting end of D before it paffed it, and alfo muft have carried it and the fpring C, together with the pallet *a*, towards the wheel, until the pallet *d* cleared the extreme end of D; alfo that the impulfe given in paffing muft have been of a continuance depending on the quantity that the end of the fpring D prefents of its length to the paffing pallet *d*; in the returning vibration, there will be the fame continuance of the impulfe given by the pallet *d* to the fame fpring D in a contrary direction, but then the flender fpring is the only one to be moved, and it yields to the flighteft impulfe, thereby occafioning no fenfible derangement in the fcale of forces by which the regulating fpring controuls the balance: hence one impulfe received from the maintaining power through the medium of the train, by the face of the great pallet during the angle of its action, or rather of the efcapement wheel's action on it, is fufficient to overcome all the friction and refiftance the balance meets with, from whatever fource, and to perpetuate its vibrations. From the prefent pofition of the refpective parts of action, it is alfo eafy to fee, that the impulfe given to the end of fpring D muft have taken place a very fhort time before the tooth 1 caught the face *c* of the large pallet, on which time depends the quantity of *drop* of tooth 1, before it comes into action; which drop ought to be very fmall, left an accelerated force fhould impel the large pallet with a jerk, and endanger fome of the finer pivots. Mr. Pennington tells us, that the prefent pofition of pallet *d* is very nearly that in which the balance fpring ought to be quiefcent, in order that the chronometer may be well in beat, a circumftance not noticed in Mr. Arnold's account, but a very effential circumftance to be known, when we judge of the fitnefs of the efcapement for anfwering its purpofe for a long continuance; for, as the momentum of the balance is always a maximum when it paffes the quiefcent point of its regulating fpring, or, in other words, when the force of this fpring ceafes to be accelerated, and begins to be retarded, it is acknowledged, we believe, univerfally, that the nearer this point of greateft momentum the balance is, when the unlocking pallet makes its ftroke, the lefs is the derangement in the uniformity of the balance's motion, which its regulating fpring is intended to produce: but, it has been faid, that the prefent pofition is that of original quiefcence of the regulating fpring; and it will be obferved, that there is an arc of feveral degrees contained between the extreme ends of pallet *d*, and fpring D, if a circle were defcribed to touch them both; whence, it might be concluded, that the pallet *d* ought to touch the end of fpring D, when the regulating fpring is at its quiefcent point, for then the ftroke would be made exactly at the moment of its having the greateft momentum: fuch conclufion might be good in theory, and, indeed, this is the pofition which Mr. Earnfhaw has given in his drawings, when he defcribes his balance as being in a ftate of quiefcence; but we fhall referve what we have to fay further on this important point, till we come to fpeak more particularly of Mr. Earnfhaw's efcapement in our following fection. In the mean time, we will only generally obferve, that, to put a chronometer, with a detached efcapement, *into true beat*, the pallet *d* muft be in the middle of the arc of efcapement, which we fuppofe to be nearly in the pofition of our figure, when the balance-fpring is quiefcent. Any further notice here on the mode of acting in this efcapement, we think unneceffary. *Figs.* 3 and 4, exhibit Mr. Arnold's balance; the former fuppofes the eye placed over the centre, and the latter at one fide in a line paffing through its plane. The circular bar of metal *a*, *b*, carrying three weights of adjuftment for pofition, within the expanfion pieces *c*, *d*, in *fig.* 3, we underftand, were added to the original balance by Mr. Arnold junior; but the generality of his chronometers have not had fuch addition, being capable of the neceffary adjuftment without.

The expanfion rims, which are about the third portion of a circle each, were originally foldered together by an intermediate mixture, and bent into the requifite fhape by a pair of pliers fhaped on purpofe to give the defired curve regularly; and, in fome of the *beft* chronometers, Mr. Arnold informs us himfelf, that he ftill continues this practice, which is greatly reprobated by Mr. Earnfhaw; we will not undertake to decide the practical queftion, which, in theory, we fhould have lefs difficulty to decide; the regularity of weight and fhape enfured by turning in the lathe, which was at firft the fenior Brockbank's practice, and is fince that of

Mr.

Mr. Earnſhaw, who formerly worked under him, ſeems to promiſe fairly for anſwering the purpoſe beſt, particularly when two metals only are united by fuſion; but, it is contended by Mr. Arnold, that the true figure given in the lathe no longer remains when the ring is cut into portions, ſuch as halves or thirds; for he ſays, the ſeparate parts aſſume, by their elaſticity, an inſtantaneous alteration in their figure, generally becoming portions of a circle of ſmaller radius than that of the original ring, and the ſeparate portions do not always undergo a change exactly ſimilar, owing to circumſtances which cannot be eaſily detected. To ſatisfy our doubts reſpecting this objection to turning an expanſion ring in a lathe, we applied to Mr. Pennington, who is allowed to be inferior to none of his contemporaries in practical ſkill, in all the different conſtructions of modern date, and we find it to be his practice, like Mr. Arnold's, not only to bend his expanſion pieces with pliers, but alſo, to ſolder them previouſly, as he formerly did thoſe of Mr. Mudge's; and he is convinced that his balances, though perforated in many places to receive various ſcrews of adjuſtment, are as ſenſibly and regularly obedient to the changes of temperature as thoſe of any other maker: it may be proper to add here, that Mr. Pennington has an excellent regulator, with a compenſation pendulum of a peculiar conſtruction; and that he has lately fitted up a little room with an inſulated brick and ſtone pillar for his tranſit inſtrument; of which he is fully acquainted with the uſe and neceſſary adjuſtments.

The ſcrews *d*, *d*, in *figs.* 3 and 4, are for rate; the cylindrical pieces, *c* and *c*, tapped for the ſcrews at the ends of the expanſion pieces, and having little holes at their exterior ends for a fork ſcrew-driver, are for the adjuſtment for temperature; and the two additional ſcrews, *e* and *e*, are for the adjuſtments for poſition, particularly when the interior ring *a b* is not introduced: theſe laſt ſcrews, *e*, and *e*, when uſed for poſition, will alter the momentum of the balance, and conſequently the rate of going, if one of the two is not juſt as much ſcrewed in as the other is ſcrewed out, when the rate is previouſly adjuſted, unleſs, indeed, there is a difference in their relative dimenſions and weights, which, in this caſe, would interfere with the adjuſtment for temperature.

Mr. Arnold uſes a cylindrical ſpring with his balance, and is very particular in aſcertaining the exact effective length that ſhall produce the ſame rate, whether the arc of vibration be long or ſhort; the trial of this adjuſtment is made by uſing the main-ſpring greatly relaxed, or let down by its ratchet, and again when it is ſet high, or has its intenſity increaſed; which alteration is equivalent to an addition or ſubtraction of weight in the maintaining power of a clock in order to increaſe or diminiſh the arc of vibration in a pendulum. When the chronometer is new, or clean if uſed ſome time, the ſemi-arc of vibration varies according to circumſtances from 180° to 230°, making in the whole vibration from a circle to 460°; but, when the oil grows thick, or when dirt has obtained admiſſion into the upper part of the train, the arc will ſometimes be reduced to 240°; ſo that, if the long and ſhort arcs were not performed in the ſame time preciſely, an alteration would take place in the rate, which might be conſiderable enough to do away all dependence on an accurate meaſurement of time. The balance-ſpring is uſually made by Mr. Arnold of ſteel wire hardened and tempered, though he ſays that wire hard rolled, or wire made of gold with a mixture of from one-eighth to one quarter of copper, will do; but the two latter are leſs permanently elaſtic, and the hard rolled wire will ſometimes require to be tapered, at that end which is next the balance ſtud: the beſt length of a balance-ſpring, which is longer in box than in pocket chronometers, lies between 5 and 20 inches to become iſochronal; but Mr. Arnold does not ſeem to apprehend, that there are various intermediate lengths, as Mr. Pennington aſſerts, which are equally iſochronal. In the box chronometer, which has a heavier balance than the pocket one, and a ſlower train, the weight is taken from the ſupporting pivot of the verge, by an ingenious application of the cylindrical regulating ſpring thus; when the ſpring is wound round a cylinder, to be blued, the coils are put contiguous, which ſhape would be afterwards preſerved from the elaſtic temper then given to it, if no force were to ſeparate them; but when one end of the ſpring is attached to the verge collet, and the other to the ſtud, theſe oppoſite ends are forcibly removed from each other to ſuch a diſtance, that the coils are ſeparated from contact, and the effort, exerted to bring them again into contact by their elaſticity, lifts nearly the whole weight of the balance. Formerly, there was a contrivance for banking in Mr. Arnold's chronometers, but the banking pin or lever rubbing between two coils of the ſpring, was found to be injurious, and was therefore laid aſide; and we do not learn that any other banking has been ſubſtituted. Mr. Arnold lays great ſtreſs on his ſtud being placed ſo as to fix the end of his balance-ſpring at half the diſtance between the centre and circumference of the coils, ſo that the laſt coil, at each end, is made ſo much ſmaller than the reſt, as prevents any protruſion of the large coils, and preſerves the cylindrical ſhape apparently unaltered by the action.

We underſtand, that neither of the two Arnolds ever placed a chronometer for trial at the Royal Obſervatory, for the expreſs purpoſe of applying for parliamentary remuneration; but we have ſeen, under our account of Mr. Mudge's time-keeper, that Nos. 36 and 68 were tried againſt his, and pronounced to be ſuperior, both with reſpect to their accurate going, and alſo in regard to the ſimplicity and practicability of their conſtruction; ſo that 1322 l. were given to Mr. Arnold ſenior by the Board of Longitude at different times by way of encouragement, and 1678 l., its complement to 3000 l., were given in December 1805 to Mr. Arnold junior, being at the ſame time that 2500 l. were given to Mr. Earnſhaw, in addition to the 500 l. which he had previouſly received. When the queſtion was difficult to decide, whether Mr. Arnold's or Mr. Earnſhaw's chronometers were moſt worthy of public reward; the Board of Longitude very properly rewarded the labours of both theſe makers.

Mr. Arnold, like Meſſrs. Brockbanks, was deſired to lay before the Board of Longitude ſome of the rates of chronometers made by his father and himſelf, which have not been returned to him, but the public are in poſſeſſion of the certificates of ſeveral rates which Mr. Arnold publiſhed in the year 1791; which rates are copied into Mr. Dalrymple's publication, together with ſome additional teſtimonies, which are too long for us to introduce here, and which, therefore, we muſt requeſt thoſe readers to refer to, who wiſh to be informed of all the particulars ſtated in the certificates; it is ſufficient, for the purpoſes of the general reader, that we have given him the peculiarities of the conſtruction of the chronometer itſelf, together with an hiſtorical notice of Mr. Arnold's inventions, and an account of the mode of action of the eſcapement; the general merit of chronometers of this conſtruction no diſintereſted perſon, that we know of, has yet denied.

Chronometer by *Mr. Earnſhaw.*—For the ſame reaſon that we have not given the movement and parts of the chronometer contained in the frame of Mr. Arnold, we think it

G not

not necessary particularly to describe all the parts of Mr. Earnshaw's that are common to the other modern chronometers. The peculiarities of the construction are confined to the balance, the balance-spring, the escapement-wheel, and the acting parts of the escapement. To these parts, therefore, we propose to confine our account. Mr. Earnshaw says, that his train is the best possible, viz. 1800 vibrations of the balance in an hour, which, we have seen, has always been the train of the other chronometer-makers, particularly for the pocket ones; his box pieces have 13 teeth each in the escapement-wheel, and his pocket ones 15, like those of Messrs. Brockbanks'; we are not told what pinions are used in the movements; nor is it said, in Mr. Earnshaw's account delivered to the Board of Longitude, that this is a consideration of any moment. *Fig.* 5 of *Plate* XIV. is an exact copy of Mr. Earnshaw's *fig.* 1 of his *Plate* III., which was taken from his model laid before the Board of Longitude on June 7th, 1804, at the same time that Mr. Arnold's model was produced; the plate and cocks, being not necessary for explaining the mode of action, are in our figure omitted. Mr. Earnshaw has given so minute an account of his escapement accompanying the model, that we cannot describe it better than by copying his own words, which are nearly these: viz.

"The small wheel M S K is called the large pallet; it is a cylindrical piece of steel, having a notch or piece cut out of it at *l h r;* against the side of this notch is a square flat piece of ruby, or any hard stone, *h l*, ground and polished very smooth, and fixed fast into the pallet. The cylinder is so placed, with respect to the balance-wheel, that it may not be more than just clear of two adjoining teeth. E F is a long thin spring, which is made fast at one end, by being pinned into a stud, G, and made to bear gently against the head of an adjusting screw, *m:* the other end is bent a little into the form of a hook; to this spring there is fixed another very slender spring at *y*, which projects to a small distance beyond it. This small spring lies on the side of the thick spring nearest to the balance-wheel. The adjusting screw, *m*, takes into a small brass cock, at *a p*, which is screwed fast to the upper plate by a strong screw. Upon the spring E F there is fixed a semi-cylindrical pin, which stands up perpendicular upon it, and of a sufficient length to fall between the teeth of the balance-wheel A B C D. This pin is called the locking-pallet, and is placed on the opposite side of the spring represented to view. Through the centre of the cylindrical pallet M S K, a strong steel axis passes, called the verge; the pallet is made fast to this axis, which also passes through the centre of the balance, and is made fast to it; it has two fine pivots at its extremities, upon which it turns very freely, between two firm supporting pieces of brass, screwed firmly, and made as permanent as possible, by steady pins, to the principal plate. A little above the cylindrical pallet M S K is fixed a small cylindrical piece of steel, *i n*, having a small part projecting out at *i*, through which the verge also passes; this is called the lifting pallet, (and is from $\frac{1}{3}$ to $\frac{1}{2}$ the diameter of the large pallet); it fixes upon the verge like a collar, and is made fast by a twist, so as to be set in any position with respect to the large pallet M S K. The end E G of the long spring E F being made very slender, if a small force be applied at the point *o* to press that end out from the wheel A B C D, it easily yields in that direction, turning, as it were, upon a centre at G; it is also made to slide in a groove made in this stud, in such a manner that the end *o* may be placed at any required distance from the centre of the verge. Having described the several parts as they appear in the figure, we next come to their connection or situation with respect to each other. Let the long spring E F be supposed to be so placed, that the end of the slender spring *y i* may project a little way over the point of the lifting-pallet *i n*, but not so close but that the point of the pallet may pass by the hooked end of the spring E F without touching it; the head of the adjusting-screw *m* is also supposed to bear gently on the inner side of the said spring E F, or that nearest to the wheel, and at the same time the locking-pallet is so placed, that one of the teeth, D, of the balance-wheel may just take hold of it. This pallet is not visible in its proper place in the figure, being covered from sight by the screw *m*, and part of the spring E F; its position is therefore represented by the dot *k*, on the opposite side of the wheel, having the tooth A just bearing up against it. From the above description of the several parts of the escapement, and their connection with each other, it will be easy to see the mode of its action, which is as follows:

"A force being supposed to be applied to the balance-wheel, so as to cause it to move round in the direction of the letters A B C D, one of the teeth, as D, will come against the locking-pallet (as represented at A, and the locking-pallet by *k*). The wheel is then said to be locked, being prevented from moving forward by this pin. Let the balance be now supposed to rest in its quiescent position, and it will have the situation represented in the figure; the lifting-point *i* of the pallet *i n* will be just clear of the projecting end of the slender spring, the face *h l* of the large pallet M S K will fall a little below the point of the tooth B, and the balance having its spiral or helical (meaning cylindrical) spring applied to it remains perfectly at rest in this position. Now, as the balance and the two pallets M S K and *i n* are fixed fast to the verge, it is plain they must all move together; let, therefore, the balance be carried a little way round in the direction of the letters M S K; by this motion the end *i* of the lifting-pallet *i n* will be brought to press up against the projecting end of the slender spring, and as this spring is fixed on the side of the spring E F, nearest to the balance-wheel, the point *i* will press the two springs together out from the balance-wheel; then, as only the point of the tooth D (see its position at *k*) touches the locking-pallet, when the spring E F was at rest against the head of the screw *m*, it will, by the spring being pressed out from the tooth, have slipt off (for the locking-pallet which was before supposed at *k*, will now be at *a*, clear of the tooth A of the balance-wheel); the wheel being now at liberty will move round by the force supposed to be applied to it; but as the point *i* of the lifting-pallet moves on and presses out the spring, the point *l* of the large pallet approaches towards the point of the tooth B of the balance-wheel, so that when the spring E F is sufficiently pushed out to unlock the wheel, the point *l* of the large pallet will be got to *d*, and in this position the point of the tooth B of the balance-wheel will fall upon it, at the same time the point of the tooth D has just dropped off from the locking-pallet *m;* the force of the wheel being by this means applied to the top of the pallet *h l*, gives an increased momentum to the balance, and assists it in its motion in the same direction, and by the continued motion of the large pallet in the direction M S K; the point of the tooth B, which keeps pressing and urging it forward, moves up towards the bottom of the face of the pallet towards *h*, until the plain flat surfaces of the tooth and pallet come into contact; by this time the end, *o*, of the slender spring has dropt off from the point, *i*, of the lifting-pallet, and the two springs have returned again into their quiescent position, the spring, E F, gently bearing against the head of the adjusting screw, *m*, and the locking-pallet in a position to receive the next tooth,

C,

C, of the balance-wheel. When the two furfaces of the tooth and pallet are thus in contact, the greateft force of the wheel is exerted upon the pallet, and of courfe upon the balance moving with it. The tooth ftill preffing againft the face of the pallet, and the pallet moving in the direction MSK, it at laft drops off, leaving the balance at perfect liberty to move on in the fame direction in which it was going. Juft as the point of the tooth B, which has been preffing the large pallet round, is ready to leave it, the next tooth, C, of the wheel is almoft in contact with the locking pallet m, fo that the inftant the tooth B drops off, the wheel is again locked, and the action of that tooth upon the balance is finifhed. As the balance moves with the greateft freedom upon its pivots, the force of the tooth has given it a confiderable velocity, fo that the balance ftill keeps moving on in the fame direction, after the preffure of the tooth is removed by flipping off from the pallet, until the force of the pendulum-fpring (which is not reprefented in the figure) being continually increafed by being wound up, overcomes the momentum of the balance, which, for an inftant of time is then ftationary, but immediately returns by the action of the pendulum-fpring, which exerts a confiderable force upon it in unwinding itfelf. As the balance returns, the point i of the lifting pallet $i\,n$ paffes by the ends of two fprings, EF, γ o, and, in paffing by, pufhes the projecting end, o, of the flender fpring in towards the balance-wheel, until it has paffed it; after this, the projecting end o again returns and applies itfelf clofe to the hooked end of the fpring EF, as before. The fpring $\gamma\, o$ is made fo flender, that it gives but little refiftance to the balance, during the time the point i of the lifting pallet is paffing it, and of courfe caufes but little (if any) decreafe in its momentum. During the time the point i of the lifting pallet is paffing in the fmall fpring $\gamma\, o$, the long fpring EF remains fteadily bearing againft the head of the adjufting fcrew m, as the hooked end at o juft lets the end of the lifting pallet pafs by without touching of it. As the fpring has now been continually acting upon the balance, from the extremity of its vibration in the direction MSK, it has given it the greateft velocity, when the point i of the lifting pallet is paffing the end o of the flender fpring; for at this inftant the fpring which was wound up by the contrary direction of the balance, is now unwound again, or in the fame ftate as it was in its quiefcent pofition at firft, and of courfe has no effect upon the balance at all in either direction; but the balance, having now all the velocity it would acquire from the unwinding of the fpring, goes on in the direction SMK, until the force of this fpring again ftops it and brings it back again, moving in the fame direction as at firft, with a confiderable velocity. By this return of the balance, the point i of the lifting pallet comes up again to the projecting end o of the flender fpring, pufhes back the long fpring EF, and unlocks the wheel; and another tooth falling upon the face of the pallet $h\,l$ gives frefh energy to the balance; and thus the action is carried on as before."

In this quotation we have given the original letters of reference, but as the balance and cocks are left out in our *fig.* 5, the direction of the balance has been indicated by the letters referring to the large pallet, which, being placed on the fame verge, has the fame motion. We have added two dotted lines in the large pallet to fhew that the direction of the lines, bounding the notch in the circumference, is towards a point in the radius of it, equally diftant from its centre and circumference; alfo we have added two fimilar dotted lines from two feparate teeth, to fhew that the undercutting or floping of the interior fide of the tooth is likewife directed to a point equally diftant from the centre and circumference of the wheel, which point is at double the diftance from the centre compared with the point guiding the undercutting flope in Meffrs. Brockbanks' chronometers; for the interfecting dotted lines form tangents to the dotted circle defcribed with half the radius of the wheel. The locking fpring points directly to the balance arbor, but is laid in fuch a way as not to be an exact tangent to a radial line drawn from the centre of the wheel to the locking pallet, the angle formed at the pallet being fomewhat lefs than a right angle, in order, as Mr. Earnfhaw fays, "that the wheel may have a tendency to draw the fpring into it," for fafe locking. The efcapement wheel, balance, balance-fpring, pallets and fprings for locking and unlocking are at the outfide of the upper plate, and are prefented to view when the cock is taken off. We hardly underftand Mr. Earnfhaw's reafoning, when he fays that his fcape wheel "unlocks in a fimilar circle which the wheel makes, which renders it a perfect dead fcape," and that "Mr. Arnold's is locked on the other fide of the wheel, and in the act of unlocking the fpring moves in towards the centre of the wheel, which is a different direction to that which the wheel takes, and produces a recoil." In the firft place we are at a lofs to conceive how the pallet on the detent-fpring and the point of a tooth in the wheel can move in a *fimilar circle*, to fize, or direction of motion, unlefs the radii are alike, and the centres of motion coincident; and in the next place, we fee no reafon to conclude that a pallet carried *directly from* the centre of the wheel's motion fhould be confidered in the fame direction as that of a tooth in the wheel, any more than a pallet carried *directly towards* the centre of the fame, in the act of unlocking; in both cafes, if the detent fpring is a tangent to the tooth of the wheel that holds the pallet, the motion *in* or *out* will be at right angles to the circumference of the wheel, and if the tooth is confiderably undercut there muft neceffarily be a recoil in both cafes. The only correction for this is, to make the angle formed by the detent fpring and radial line of the wheel at the refting pallet, to be as much lefs than a right angle, as the angle of undercutting is; accordingly Mr. Earnfhaw fays he has made this angle a little lefs than a right angle, but then he has undercut his tooth much more than the difference, and therefore, as appears to us, there muft be recoil, or a little backward motion in the fcape wheel, in the act of the detent pallet's efcaping; whereas Mr. Arnold's locking pallet refts againft a ftraight line directed towards the centre, which is alfo the direction of the pallet's motion in unlocking, confequently there can be no fenfible recoil in his efcapement. In our defcription of Mr. Arnold's efcapement the reader may recollect that he was referred to this place for fome further account of the proper *adjuftment for beat* in a chronometer of the modern inftruction, we here refume the fubject with an obfervation of Mr. Earnfhaw himfelf which we have already quoted; "let the balance, fays he, be now fuppofed to reft in its quiefcent pofition, and it will have the fituation reprefented in the figure," alluding to the figure which we have copied: we prefume not, merely upon the ftrength of our theoretical reafoning, to affert, that the adjuftment for beat is improper, if the balance fpring is quiefcent when the face of the lifting pallet i is in contact, or nearly in contact with the end of the unlocking fpring $i\ \gamma$, but we are affured by workmen well qualified to judge, and who give fcientific reafons for the affertion, that the lifting pallet is not only about 24° on one fide of the requifite point of pofition, but is actually at the wrong fide of the unlocking fpring; the reafon given us is this, whenever a chronometer is in *true beat*, the quiefcent point from which the excurfions of the balance commence is is in the *mean point* of the angle of escapement; this is obviously the case in the anchor escapement of a pendulum clock, and requires a necessary adjustment when the clock is at first fixed up; and a little consideration will prove that an attention to this adjustment, though not equally obvious, is equally desirable in a chronometer. What is called the angle of escapement differs from what is called the angle of action, or angle of impulse, in a chronometer; the former is included in the arc comprehended between the point where the unlocking spring lets go or escapes the face of the lifting pallet, and the point where the impelling tooth of the wheel drops off or escapes from the face of the large pallet; but the second, or arc of impulsive action, is comprehended, between the point where the impelling tooth commences, and the point where it terminates its action; this second arc is smaller than the former, and is always contained in it; the two have indeed one common termination, but each has a separate commencement; for the wheel must necessarily be unlocked before its action on the large pallet can begin, and the unlocking takes place previously to the unlocking or lifting pallet's quitting the end of the unlocking-spring: if we suppose that the slender spring *i q* bends back, the space of 4°, more or less, before the unlocking-pallet *n i* quits it, after the wheel is unlocked, this quantity will constitute the difference between the arc of escapement and the arc of the wheel's action, provided there be no drop of the impelling-tooth on the heel of the large pallet after the wheel is unlocked, and before the action commences; but if we suppose the said drop to be also 4°, then will the whole arc of escapement exceed the whole arc of action on the pallet by 8°. Admit now that the escapement-wheel and large pallet have their diameters to each other as 2 : 1, which is the ratio Mr. Earnshaw in general adopts, and that this wheel have 13 teeth, which is the number in his box-chronometer; then $\frac{360°}{13} = 27°.7$ nearly, is the distance between the points of two successive teeth; admit also that there be a second drop of 2° from the tooth to be locked to the locking-pallet after the arc of action is finished; then the sum of the two drops, $4 + 2 = 6°$, that precede and follow the arc of action, being subtracted from 27°.7, or whole distance between the two nearest teeth, leaves 21°.7 measured on the circumference of the wheel for the total arc of action on the pallet; but the wheel is double the diameter of the pallet, therefore, the same quantity is $21°.7 \times 2 = 43°.4$ measured on the circumference of the large pallet, and the arc of escapement exceeds the arc of action, on our supposition, by 8°, consequently, $43°.4 + 8° = 51°.4$ will be the arc of escapement: now it will be seen, on referring to the plate, that Mr. Earnshaw has placed his lifting-pallet in the figure within less than 4° of one of the two extremities of the arc of escapament, and on that side of the unlocking-spring *i y*, towards which this spring bends at the instant of the lifting-pallet's final escape; and yet he says that this is its situation when the balance-spring is in a state of quiescence; let us try what will be the consequence of such a position; the chronometer will measure time very well, and the impulse of the lifting-pallet, we allow, will be given at the most favourable instant, namely, at the instant of the spring's quiescence, or point of the balance's greatest momentum, which, it is evident, was Mr. Earnshaw's reason for fixing his lifting-pallet so; but then, which is our objection, as one excursion of the balance from the point of rest must necessarily be 47°.7 (51°.4 − 4°) before it clears the arc of escapement, and as the excursions must be similar to the right and left, when the balance vibrates freely, the whole arc of vibration can never be diminished to less than 95°.4, in this case, without the chronometer's stopping, which, as the chronometer has not the power of commencing motion of itself, is a very serious objection to the present position of the lifting-pallet; it may, indeed, be said, in reply, that the chronometer must be very dirty before its arc of total vibration becomes so much diminished as to be little more than a quarter of a circle, but this is not the only predicament in which the stoppage will take place; any sudden check, or quick horizontal motion given to the vibrating balance, that makes it return even once before it has exceeded this limit, will bring it to rest; that is, nearly the same effect will be liable to be produced as if the arc of the escapement had been almost double the present quantity with a pallet of ½ the diameter of the wheel, which is Mr. Earnshaw's cogent objection to Mr. Arnold's construction. In making this comparison with a double arc of escapement, we, of course, suppose the point of the lifting-pallet's quiescence to be in the middle point of the arc of escapement, as Mr. Arnold's appears to be in his figure, which we have copied, and which situation we now proceed to show, is most favourable to the continuance of the chronometer's going without interruption with any given pallet. We propose to place the lifting-pallet's face exactly in the middle point of the arc of escapement, which is not a theoretical proposition of ours, but we have examined chronometers adjusted so for beat, and have found that, when the balance is drawn round a trifle beyond either extremity of the escapement-angle, they have the power of commencing motion within a limit very little exceeding the escapement-angle, which, in Mr. Earnshaw's box-chronometer, we have shown, may be about 51°.4. Hence the chance is almost two to one in favour of that chronometer's avoiding stoppage by dirt or accident, which has its quiescent lifting-pallet in the middle of the arc of escapement, compared with that which has the same pallet at one end of the same arc.

The only objection which carries the semblance of argument against our mode of adjustment for beat, an adjustment we believe too generally overlooked, is, that the impulse of the lifting-pallet is not at the moment of the balance's greatest momentum, but about 24° before the momentum is a maximum, allowing the pallet to be quiescent at the middle of the arc of escapement, which we contend for; our reply is, that the momentum is so nearly a maximum at 24° from it that the difference produces no sensible bad effect on the balance, compared with the probable effect from stoppage when the adjustment for beat is nearly as bad as possible. Indeed, Mr. Atwood has calculated, and his calculations seem to have been verified by practice, that when, in the case of Mr. Mudge's time-keeper, the quiescent point of his auxiliary spring is at one side of the quiescent point of his stronger spring, the effect produced is a daily gain or daily loss in the rate, accordingly as the distance from coincidence of the respective points of rest fell on the right or left hand side of the quiescent point of the strong regulating spring, and the daily gain or loss thus to be effected is ingeniously proposed, in our author's excellent paper in the Philosophical Transactions of 1794, to be used as an adjustment for rate, or even as a compensation for want of isochronism in the balance-spring. The deduction from the momentum of the balance, occasioned by the impulse of the lifting-pallet, being somewhat analogous to the want of adjustment in the quiescent point of Mr. Mudge's auxiliary spring, might indeed produce a slight loss in the daily rate, if the screws of adjustment for rate did not compensate such loss; but when it is considered that the impulse from the wheel succeeds the deduction from the momentum almost instantaneously, and that the deduction

we

we ſpeak of is preciſely the ſame in each vibration, the uniformity of the going of the chronometer will not be ſenſibly altered thereby.

Let us ſee, in the next place, what will be the arcs of action and of eſcapement in Mr. Earnſhaw's pocket chronometers, in which the eſcapement-wheel has 15 teeth; $\frac{360°}{15} = 24°$ is the diſtance between two contiguous teeth, from which ſubtract, on our former ſuppoſition, 6° as the ſum of the preceding and following drops, and the angle of action will be 18°, or 36° meaſured on the circumference of the large pallet, if it be half the ſize of the wheel; but the angle of eſcapement will be greater than the angle of action by 8°; therefore $36 + 8 = 44°$ is the whole arc of eſcapement, ſuppoſing, as before, the data for the drops to be accurate. This angle of eſcapement turns out to be leſs, on our ſuppoſition, than that with only 13 teeth in the eſcapement by 7°.4, and therefore will admit a lifting-pallet ſmaller than the box chronometer has, in order to have the ſame angle of eſcapement, or the ſame liability to ſtop by dirt or accident; it being ſelf-evident that the ſame ſubtending line, conſidered as a chord, will meaſure more degrees on the periphery of a ſmall circle than on the periphery of a larger. This compariſon of the two arcs of eſcapement ſhews, that the arc in queſtion depends not entirely on the relative diameters of the eſcapement and large pallet, as Mr. Earnſhaw ſuppoſed, when he objected to Mr. Arnold's proportions, but on their relative diameters conjointly with the number of teeth in the wheel, the latter of which has been overlooked by Mr. Earnſhaw, but particularly inſiſted on by Mr. Arnold. However, we agree perfectly with Mr. Earnſhaw, that in any wheel with a given number of teeth, a large pallet for receiving the impulſe of the wheel will require a ſmaller arc of action as well as a ſmaller arc of eſcapement, than a pallet that has a ſmaller diameter, under any given adjuſtment for beat, which is a conſideration worthy of general notice.

On counting the teeth in Mr. Earnſhaw's eſcapement-wheel, which we have copied, we were ſurpriſed to find only 12 teeth in it, particularly as we are informed, in his deſcription, that his numbers are 13 and 15 reſpectively; we can only account for this circumſtance by ſuppoſing that the draftſman miſtook the number; which we here notice, leſt the reader ſhould ſuppoſe the fault to lie in our figure excluſively.

Fig. 6 of *Plate* XIV. repreſents Mr. Earnſhaw's balance, which, like Mr. Arnold's, has only two compenſation pieces, and thoſe much ſhorter than his, being little more than a quadrant each: *a* and *a* are the ſcrews of adjuſtment for rate, ſcrewed in to make the chronometer go faſter, and out to make it go ſlower. The ſliding pieces *b* and *b* have each a circular groove, turned in a lathe or turning-frame, deep enough to form a bed for the expanſion bars, in order that the interior ſide ſcrews *c* and *c* may preſs againſt the edges of the expanſion pieces, and retain the ſliding pieces in any given ſituation. *Fig.* 7 is a lateral view of this balance and verge without the pivots, which Mr. E. ſays ſhould be conical except very near the ends, which ſhould be cylindrical; and ſhould run in a "jewel hole as ſhallow as poſſible, ſo as not to endanger cutting the pivot; and the part of action of the hole ſhould be made quite back, with only a very ſhallow chamfer behind to retain the oil." The ſliding pieces *b* and *b* are the weights of adjuſtment for temperature; in making theſe weights, a braſs ring is firſt made in the lathe, and is then cut through into fourteen equal parts in a clock-engine, by an operation ſimilar to that of cutting a wheel into fourteen teeth, ſo that each piece is the fourteenth part of a circle, after deducting the thickneſs of the cutter, which is not mentioned. One of the weights in a box chronometer, is about twenty grains generally. The expanſion rims are turned out into a ring from a circular compound plate, which is made after the method of Meſſrs. Brockbanks, by fuſing the braſs in a crucible, containing the ſteel circle, held in a horizontal poſition during the time of fuſion. The conſtruction is very ſimple, but, as it appears to us, if the adjuſtments for poſition were made by means of the ſcrews of rate, and weights for temperature only, one adjuſtment would derange another, and that for poſition would be very difficult to make nicely, as there is no tangent ſcrew, or other contrivance, to move the weights *b* and *b* by gradual ſlow motions. As though to get rid of this objection, which was too obvious to be overlooked, Mr. E. conceives that the cauſes of a difference in the rate in different poſitions, are large balance pivots in part, but principally the badneſs of the balance-ſpring; his words reſpecting the latter cauſe, are theſe; "much difficulty has fallen to the lot of watch-makers in the endeavour to make time-keepers go nearly the ſame in the different poſitions: I have had my ſhare of this, but it is now over; by far the greateſt part of this difficulty ariſes from the balance-ſpring not being properly made. But if the ſpring is made as I ſhall deſcribe hereafter, you have only to make the balance of equal weight, and it will go within a few ſeconds per day in all poſitions alike; and if it vibrates not more than one circle and a quarter, by applying a ſmall matter of weight to that part of the balance, which is downward, when in the poſition that it loſes moſt, (it) will correct it with great accuracy."

The Board of Longitude not knowing what this "ſmall matter of weight" implied, nor how it is to be attached to the balance, were induced to put the following queſtion, viz. "When the weight is wanted to adjuſt the watch in the poſitions of 3 and 9, by what means do you obtain that weight, in the manner your balance appears to be made; if you know any thing more that is material concerning the making time-keepers go nearly the ſame in different poſitions, communicate it."

Anſ.—"To adjuſt the watch in the poſitions of 3 and 9, (ſays Mr. E.) I fix on to one of the compenſation-weights that is downwards, when in that poſition that it loſes moſt, a ſmall piece of braſs, not larger in diameter than a common pin-head, and nearly as thin as foolſcap paper. I fix it on with a very ſmall particle of *bees wax*, not larger than the common dot of an *i*: that is, if the watch is gaining on mean time. But if the watch is loſing, I then take out the balance, and with a drill drill out a ſmall matter from that compenſation-weight, that is uppermoſt when in the poſition that the watch loſes moſt; this I have found to correct it without ſo many ſcrews and fans as I have ſeen in ſome time-keepers." After having read the above anſwer, we were almoſt induced to examine whether the balance itſelf might not alſo be fixed to the verge-collet by bees wax inſtead of ſcrews, but we recollected that in the drawing there is a little ſcrew-head at each ſide of the centre of the balance, which appear to be uſed for this purpoſe. Mr. E. we truſt, will pardon the obſervation.

The rule for adjuſting the balance for temperature is this; put the watch into about 85 or 90 degrees of heat by the common thermometer, mark down exactly how much it gains or loſes in 12 hours, then put it into as ſevere a cold as you can get, for 12 hours, and if it gains one minute more in 12 hours in cold than in heat, move the compenſation weights farther from the arm of the balance about $\frac{1}{4}$ of an inch; and if it gains one minute more in 12 hours in heat than

than in cold, move the weights $\frac{1}{8}$ of an inch nearer to the arm of the balance, and ſo on in the like proportion, trying it again and again, till you find the watch go the ſame in whatever change of heat and cold you put it. Of courſe this adjuſtment precedes the adjuſtment for poſition, ſo that moſt probably the poſition, whatever it is, during theſe trials, is always the ſame, a circumſtance not ſpecified. The total vibration at firſt is confined to a circle and a quarter, which quantity, it is ſaid, will produce the moſt ſteady performance; but we are not informed what the banking is that limits the greateſt vibration, nor indeed whether there is any banking at all, which we have been informed there is not in general.

Mr. Earnſhaw's greateſt difficulty in the progreſs of his labours ſeems to have been to find out what he calls the *inviſible properties* of the balance-ſpring, and to render it not exactly iſochronal, but ſo nearly ſo, that its deviation from iſochroniſm may compenſate for a *relaxation* in the ſpring, real or imaginary, ariſing from conſtant uſe, which is *ſuppoſed* to affect the permanency of the rate. After complaining bitterly of much diſappointment in his firſt labours, our author ſays, "I found, in the courſe of reaſoning on bodies, that watch-ſprings *relax* and *tire* like the human frame, when kept conſtantly in motion; and this may be proved by the following experiment: let a watch, that has been going a few months, go down, let it be down for a week or two, or more, then ſet it going, and if it be a good time-keeper, ſo as not to be affected by the weather, it will go ſome ſeconds per day faſter than it did when it was let down, but it will again loſe its quickneſs in a gradual manner, gaining leſs and leſs, till it comes to its former rate. Therefore, finding that iſochronal ſprings would not do, and likewiſe having made ſprings of ſuch ſhape as would render long and ſhort vibrations equal in time, (which) conſtantly loſe (loſt) the longer the watch went; I then made them of ſuch ſhape as to gain in the ſhort vibrations about five or ſix ſeconds per day more than the long ones; this quantity could only be found by long experience; and the way I proved this, was to try the rate of the watch with the balance vibrating about $\frac{1}{3}$ of a circle, then tried its rate when vibrating a circle and a quarter, and if the ſhort vibrations go ſlower than the long ones, that watch will loſe on its rate, and if they are equal, it will likewiſe loſe, but that only from *relaxation;* and if it gains in the ſhort vibrations more than five or ſix ſeconds in 24 hours, it will in the long run gain on its rate, but if not more than that quantity, and if the time-keeper is perfect in heat and cold, and every other part, the above properties will render it deſerving of the name of a perfect time-keeper: and this is a principal cauſe of my time-keepers excelling all others; and this is the principal cauſe of ſome of my time-keepers going better than others; though by me, the ſprings of them being made to accord more exactly to the above proportions; and this is the cauſe which has enabled me to foretel what my time-keepers would do, which Dr. Maſkelyne, Mr. Croſley, and others can teſtify. The above effect is produced as follows: I find the common *relaxation* of balance-ſprings to be about five or ſix ſeconds per day on their rates in the courſe of a year; therefore if the ſhort vibrations are made, by the ſhape of the ſpring, to go about that quantity faſter than the long ones, and as the ſpring relaxes in going by time, ſo the watch accumulates in dirt (dirt accumulates in the watch more properly), and thickening of the oil (takes place), which ſhortens the vibrations, the ſhort ones then being quicker compenſated (compenſates) for the evil of relaxation of the balance-ſpring." (See Mr. Earnſhaw's "Explanation," pages 8 and 9.)

The Board of Longitude having put the following queſtions on this ſubject, "Explain what you mean by this? and how it is performed?" Mr. E. replied: "All watchmakers know how to draw and taper balance-ſprings, though they did not know how much they were to be tapered to that certain degree which could only anſwer the purpoſe of a complete time-keeper. I perform it in the following manner: take a length of balance-ſpring-wire, ſay about twelve inches for box time-keepers, and draw it between two ſmooth potence files, beginning from the end about $\frac{1}{6}$ of its length, make one draw, the next about $\frac{2}{6}$, and ſo on, advancing $\frac{1}{6}$ every draw till you come to the top, preſſing the files juſt ſo hard together as will make them bite or take hold of the ſpring; do the ſame with two oil-ſtones, only give 12 ſtrokes inſtead of 6, which will take off all burrs which the file left on." ("Explanation," p. 29 and 30.) We are further told, that when the ſpring is *tired* with long continuance of work, its vigour may be reſtored by *reſt*.

Theſe ſprings, that have the inviſible properties deſcribed, "are made of ſoft ſteel, rolled hard, and not hardened and tempered with heat and cold, that proceſs not being at all neceſſary." Their length varies in box chronometers from 12 to 20 inches, and in pocket ones from 5 to 7, like Mr. Arnold's, and the ſhape is cylindrical, with the two extreme coils, each about half the diameter of the other coils, agreeably to the ſpecification in one of Mr. Arnold's patents. The thickneſs of the ſteel in the expanſion-pieces of the balance is about $\frac{8}{1000}$ of an inch, and that of the braſs twice, or nearly three times as thick; the diameter of the balance without the weights and ſcrews $1\frac{1}{3}$, and with them $1\frac{3}{5}$ inch; the total weight of it with weights and ſcrews 3 dwts. 10 gr. The mainſpring barrel is $1\frac{3}{16}$ inch, and the depth $\frac{1}{2}$ inch, and the ſpring in it has from $4\frac{1}{2}$ to 5 turns. The weight of each of the two balance ſcrews is from 5 to 6 grains; and the figure which the expanſion pieces aſſume when cut from the original compound ring is ſuffered to remain unaltered, on a ſuppoſition that bending by any mechanical means will injure the regularity of their obedience to the changes of temperature; the locking and unlocking ſprings are made as weak at the bending parts as are practicable to afford the neceſſary reſiſtance, as a detent, to the eſcapement-wheel; they are brought to ſhape by filing, then ſmoothed with a piece of ſteel and oil-ſtone powder, and laſtly hardened and tempered. The pallets, which are of ſteel, have each a jewel ſet in them, and thoſe on the verge of the balance are twiſted round, and ſet to their ſituations reſpectively by the friction of their central holes. In his laſt anſwer to the queſtions of the Commiſſioners of Longitude, when aſked, "How ſhould the lifting and large pallet be placed with reſpect to each other?" Mr Earnſhaw's words were, "the ſmall lifting-pallet muſt be moved round to ſuch poſition that when the wheel is unlocked the face of the large pallet ſhould be juſt within the compaſs of the wheel-tooth which is to act on it;" but, what appears to us remarkable, no queſtion was aſked by the Board, nor any particular notice taken, that we can find, either by Mr. Arnold or Mr. Earnſhaw, reſpecting the relative poſitions of the lifting-pallet and the quieſcent point of the regulating ſpring, excepting in the inſtance of Mr. Earnſhaw, that we have had occaſion to notice; which notice, we truſt, will benefit not only him, but moſt of the other makers of chronometers, with the detached ſpring-detent eſcapement.

The mention of this eſcapement brings to our recollection a patent which was ſaid to have been taken out for the invention of a detent-ſpring in the name of Wright, a Quaker in the Poultry, and which was, till lately, conſidered to be

Mr. Earnfhaw's patent, but which was never actually taken out, as we have been lately informed from good authority; what part of the fpring conftituted the pretended invention, and how it differed from Mr. Arnold's fpecification, we are not informed; the only difference that we are aware of is, that one fpring-detent unlocks inwards, and the other outwards; but Meffrs. Brockbanks' have always unlocked outwards, though they have not the two fprings inferted into one another, as Meffrs. Arnold and Earnfhaw have: neither do we fee any good reafon for preferring one of the three conftructions to either of the other. They have all been found to anfwer the defired purpofe; and the three makers, who have feparately fold each a thoufand chronometers or thereabouts, have turned out of their hands fome machines that have performed but indifferently, as well as others, that have done them great credit, as well as the navy great fervice.

"Two time-keepers, fays Dr. Mafkelyne, in his preface to the "Explanations," publifhed by order of the Commiffioners of Longitude, conftructed by Mr. Thomas Earnfhaw, were tried three feveral times at the Royal Obfervatory, by order of the Commiffioners of Longitude, for a twelvemonth or more at a time between 1798 and 1802, as candidates for fome of the great rewards held out by the act of parliament of the 14th of his prefent Majefty; but were adjudged not to have gone within any of the limits prefcribed by the act, and, therefore, not thought proper to be fent to fea, to undergo the fubfequent trial required by the act. However, as they appeared to have gone with fufficient exactnefs, in the two laft trials, to be of confiderable ufe in navigation, the commiffioners, on the 3d and 17th of March 1803, refolved unanimoufly to grant to Mr. Earnfhaw the fum of 2500 l. in addition to 500 l. which they had given him before." Sir Jofeph Banks baronet, however, entered *a proteft* againft this *unanimous* refolution, to which Dr. Mafkelyne has replied in a private pamphlet; which, therefore, we cannot further notice; but Mr. Earnfhaw, elated, probably, with his fuccefs, publifhed an advertifement in the public papers by no means calculated to conciliate his very refpectable opponent; in reply to which, Mr. Dalrymple, a gentleman well known to the world as a geographer, has recently written a pamphlet for public circulation, which we here notice, as impartial by-ftanders, that we may fet the author right in fome of his obfervations, which we confider as the produce of his zeal for his friend's caufe, rather than of his mature judgment. The pamphlet we allude to, is intituled "Longitude;" the author of which, fpeaking of the effects of heat and cold on the balance-fpring, and the mechanical means ufed by Harrifon and others, fays thus: "Various modes of correction were practifed; but, as *all* thefe were by *conftraint*, checking the natural effects of heat and cold on the fpring, they were found ineffectual. Mr. Arnold, imitating the fimplicity of nature in her operations, fo conftructed *his balance*, that *heat* and *cold* fhould *enlarge* or *diminifh* it, in the *fame degree* as they operate on the *fpring* of a *watch*, fo that the *effect* muft be *uniform*; the balance, by becoming *larger* or *lefs*, exactly counteracting the effect of *heat* and *cold* on the fpring." (page 13 and feq.). What Mr. Dalrymple's term *conftraint* here means, we do not exactly conceive; our opinion of Mr. Harrifon's curb, or kirb, is, that its inward and outward motion alternately affected by changes of temperature, limited the effective portion of the fpring to the *fame dimenfions*, in point of length, under all circumftances; which limit in the length of the fpring *conftrained* it, to be fure, to become an uniform regulator, or very nearly fo: but that the *enlargement* of the balance fhould counteract the effects of *heat*, or the *leffening* of it fhould counteract the effects of *cold*, is to us a new doctrine, juft the reverfe of what we have been in the habit of propagating; we beg leave to repeat, on this occafion, that the expanfion pieces of the balance are intended to preferve the effective diameter of it unchanged by heat or cold; the fame heat which elongates the radial arms brings the expanfion weights nearer to the centre, and preferves the momentum unaltered; which effect produced on the diameter of the balance is a *conftraint*, as much as the alternate lengthening and fhortening of the balance-fpring is, by artificial means, fimilar in principle, and alike in oppofition to the direct effect of natural caufes. Of the fame nature is the following opinion, in p. 80: "Before I quit the fubject, I muft obferve, that the confidential committee, to whom Mr. Mudge's time-piece was explained, reprefented the *efpecial merit* of it to be in "a contrivance for deftroying the *inequalities* of the *maintaining power* derived from the *main-fpring*." Before that time, the late Mr. Arnold had *entirely* deftroyed the *inequalities* proceeding from the *main-fpring*; this was demonftrated by an *experiment*, in prefence of feveral perfons, at Mr. Aubert's houfe in Auftin Friars," &c. The experiment here alluded to, was that of the ifochronal length of the balance-fpring, which made the long and fhort arcs of vibration to be performed in the fame times, or, in other words, which compenfated the great inequalities of the maintaining power where no fufee was ufed; fo that the contrivance did not "entirely deftroy the inequalities" proceeding from the main-fpring, but allowed them to be as great as poffible, and then compenfated thofe *increafed inequalities* by the ifochronifm of the regulating-fpring, as we have before ftated. It appears to us, that the author in queftion, at the time he made thofe feveral obfervations on chronometry, had not given himfelf time to form a diftinct apprehenfion of the difference between caufe and confequence.

Nearly of a fimilar kind does Mr. Earnfhaw's reafoning appear on the tapering of the balance-fpring, where he fays, "if a man is to go four miles in the fame time as he has gone one mile, he cannot do it with the fame power; no, he muft have impelling force to quicken his motion, or he will be four times as long in doing it. Therefore, inftead of the fpring being equal in all its parts, it muft be made to increafe in thicknefs to the outer end," &c. (Page 8, of the "Explanations.") Mr. Earnfhaw feems here to have forgotten, that in every uniform fpring, of whatever fhape, the law of its action, as afcertained long ago by Dr. Hooke, is "ut tenfio fic vis," *i. e.* the impelling force is directly as the tenfion, or diftance from the point of reft; and if he knows any thing of the law of accelerated forces, he will find, on confideration, that there is no occafion to apply two feparate caufes to produce an exact effect, when one of them, fingly, is competent to the purpofe; if, indeed, more than a due effect is to be produced, then an auxiliary caufe may be had recourfe to, but ftill we muft look to the primary caufe, for regularity as well as for the continuance of the effect, particularly as, in the cafe before us, the primary caufe is the natural one, and the auxiliary one only artificial. The fpring of uniform thicknefs will produce a fcale of accelerated velocities fimilar to that produced by the uniform action of gravity alone. Another of Mr. Dalrymple's remarks is this; "The *fpiral fpring* was found to be another fource of irregularity; as, by action, it changed its elafticity, and its *power* was not the *fame* in all parts of the *volute*;" (p. 14, "Longitude"): and he ftrengthens the force of this obfervation by adding Mr. Arnold's well known reply to the committee of the Houfe of Commons, when they afked him,

What

What objections are there to the common ſpiral-ſpring? which reply was, "that it is never a ſpiral but when it is at reſt." Our reply to theſe remarks is this, that no ſpring can act at all without motion, and, conſequently, without change of figure; nor would any ſpring anſwer the purpoſe of a regulating-ſpring, if its power or elaſtic force were the ſame at every degree of tenſion, as both Mr. Earnſhaw and Mr. Dalrymple ſeem to have perſuaded themſelves is uſually the caſe. The beauty of the law of a ſpring's tenſion is, that it does not depend on the ſhape, provided its dimenſions be uniform: indeed Mr. Earnſhaw himſelf has found out from practice, that "the only advantage attending the cylindrical ſhape is, that it is rather eaſier (more eaſily) made; a ſaving of about one hour of time." Mr. Earnſhaw has particularized ſix advantages which his eſcapement has over Mr. Arnold's, in p. 12 of his "Explanations;" but, as the reader will probably think we have detained him too long, we refer him to the original information, in reading which, he will now be able to form an opinion for himſelf as to the real exiſtence of thoſe advantages; indeed, when all reaſoning on the ſubject is at an end, that particular conſtruction of a chronometer will no doubt ultimately prevail in practice, which ſhall be found to perform the beſt, and at the ſmalleſt expence.

We might have added to our article an account of different chronometers by French makers, but, as a chronometer differs from an ordinary watch principally in the *compenſation-balance* and *eſcapement*, their properties and peculiarities of conſtruction deſcribed under theſe two heads will be amply ſufficient, after what we have here ſaid on the ſubject: and, with reſpect to our preſent article, which has grown upon our hands to a greater length than we intended it ſhould, the reader, however he may differ from us in ſome particulars, will at leaſt acknowledge, that we have, in general, taken the liberty of thinking for ourſelves, and have, moreover, freely expreſſed thoſe thoughts, uninfluenced by the authority of names, even of thoſe to whoſe aſſiſtance we are indebted; which we conceive to be the only way of doing juſtice to an intereſting ſubject, that has never before gained general circulation in the Engliſh language.

CHRONOMETER.—*Exemplification of its uſe in determining the longitude of a ſhip or place.* The reader, it is preſumed, has already obtained a general idea of the utility of a chronometer in aſcertaining the relative longitudes of any two places, from what we ſaid on this ſubject in our hiſtory of the improvements in chronometers; but if he is in poſſeſſion of one of thoſe delicate and valuable machines, and wiſhes to avail himſelf of its uſe, either at ſea or on ſhore, in determining practically the longitude of the place he is at, compared with his firſt meridian, he will ſtand in need of further and more particular directions, than we have before given, to enable him to effect the requiſite determination with accuracy. The two moſt eſſential things in uſing a chronometer, are, firſt, to be able to aſcertain its mean daily rate of going, and to apply it to the time indicated at any place and inſtant afterwards; and, ſecondly, to be able to determine by obſervations on ſome of the heavenly bodies the exact hour, minute, and ſecond, at the ſaid place and inſtant of obſervation, becauſe the difference between the corrected time indicated by the chronometer, as the time at the firſt meridian, and the equated time obtained by calculation from the obſervations, will be the exact difference of longitude in time, between the place of obſervation and the firſt meridian, to the time of which the chronometer is ſuppoſed to have been previouſly put. But each of theſe two requiſites may be obtained by various means; and as ſome of thoſe means may be in the poſſeſſion of one reader, and ſome of another, we cannot better acquit ourſelves, than by giving in ſucceſſion ſome of the principal methods, uſed by different eminent men, of effecting the ſame purpoſe, each of which methods may have ſome advantage peculiar to itſelf, which under certain circumſtances may render it moſt deſirable, or, at leaſt, moſt practicable. There are, however, certain preparatory operations which are alike neceſſary to aſſiſt the reader, whom we ſuppoſe to be previouſly unacquainted with them, to perform the calculations he will have to go through. We propoſe, therefore, to ſelect from the various authors, who have recently written on this ſubject, and to arrange in ſucceſſive order, thoſe problems in nautical aſtronomy, which we deem neceſſary in order to render our propoſed exemplification, not only eaſy by the gradation we adopt, but alſo ſufficienrly comprehenſive, by including the different methods, to anſwer the deſired purpoſe of practical application. It would lead us beyond our bounds to enter here into an account of the different inſtruments made uſe of in celeſtial obſervations, together with their various adjuſtments and modes of uſing, which are explained under their reſpective heads in the different parts of this work; we muſt, therefore, beg leave to refer the reader to thoſe heads, accordingly as he finds himſelf at a loſs for the requiſite explanations and directions. There are, however, a few ſmall tables not generally met with in books of navigation, which are neceſſary companions for a tranſit-inſtrument, when the ſtars are obſerved, and which the obſerver, who takes a rate by his tranſit-inſtrument, ſhould always have at hand: we therefore think it deſirable to prefix them here, that the reader may not only apply them in peruſing for his amuſement the ſubſequent problems, but may always have them under his eye whenever he may have occaſion hereafter to conſult our directions in practice.

We have not met with this ufeful little Table in any other Book but in Mr. Wales's Pamphlet, entitled, "The Method of finding the Longitude at Sea by Time-keepers." London, 1800.

PROBLEM

Problem I.

To reduce apparent to mean time.

Rule, (from W. Wales, F.R.S.) If the time at Greenwich be not given, turn the longitude of the place into time; and add it to the time at the given place, if the longitude be weſt, but ſubtract from that time, if the longitude be eaſt, and it will give the time at Greenwich.

Take the equation of time from page II. of the Nautical Almanac, for the noon preceding the time when it is wanted, and alſo the difference between it and the equation for the day following; and ſay, as 24^h is to this difference, ſo is the time at Greenwich to a fourth number; which muſt be added to, or ſubtracted from, the equation for the preceding noon, accordingly as the equation is increaſing or decreaſing.

Note. In every operation, where one time is to be taken from another, add 24 hours to the time you ſubtract from, if the time which is to be taken from it be the greater, and the remainder muſt be reckoned from the noon of the preceding day. When one time is added to another, if the ſum exceed 24 hours, take 24 hours from it, and the remainder muſt be reckoned from the noon of the following day.

Example 1, (from Mr. Kelly.) What is the equation of time at noon at Bombay, on the 16th Nov. 1805, the longitude of Bombay in time being $4^h\ 50^m\ 32^s$?

Equation of time for noon, at Greenwich ſub.	$15^m\ 1^s.9$
24^h is to $4^h\ 50^m\ 32^s$ as 10.8 (daily diff.) is to	+ 2.2
Equation of time for noon, at Bombay	$15^m\ 4^s.1$

Example 2, (from Mr. Kelly.) What is the equation of time at Port Royal, on July 11, 1805, at $20^h\ 23^m$?

Time at Port Royal - - -	$20^h\ 23^m\ 0^s$
Longitude of Port Royal in time	5 7.2
Time at Greenwich, July 12th -	1 30.2
Equation of time, July 12th, at noon add	$5'$ 5.6
24^h is to $7^s.5$ (daily diff.) as $1^h\ 30^m\ 2^s$ is to	+ 0.5
The equation of time ſought	5. 6.1

If it be required to convert mean time to apparent, a contrary proceſs muſt be uſed; that is, the equation of time muſt be applied with a contrary ſign: but in order to perform this problem with perfect accuracy, an allowance muſt be made for the proportion of the equation itſelf, as the table is computed for apparent noon.

Problem II.

To find the ſun's longitude for any given time and place from the Nautical Almanac.

Rule, (from W. Wales, F.R.S.) Take the ſun's longitude for noon at Greenwich from page II. of the Nautical Almanac for the given day, and its hourly motion from page III.

Enter Table IV. with the ſun's hourly motion at the top, and the longitude of the given place in time in the left-hand-ſide column, or in the right-hand column if given in degrees, and take out the correction which ſtands under the former and oppoſite the latter: this correction being added to the ſun's longitude for noon at Greenwich, if the longitude of the place be weſt, or ſubtracted from it, if the longitude be eaſt, will give the ſun's longitude for noon at the given place.

Example 1. What was the ſun's longitude at noon on the 15th of October, 1793, at Lima in Peru?

Sun's longitude for noon at Greenwich	$6^s\ 22^\circ\ 34'.8$
Hourly mot. $2'\ 29''$ and long. 77° W. give +	12.7
Sun's long. for noon at Lima	6 22 47.5

Example 2. What was the ſun's longitude at noon on the 27th of November, 1793, at Calcutta?

Sun's longitude for noon at Greenwich	$8^s\ 5^\circ\ 46'.6$
Hourly motion $2'\ 32''$ and long. 88° E. give −	14.9
Sun's longitude for noon at Calcutta	8 5 31.7

When the time is for any hour before or after noon, a ſecond ſimilar reduction will be neceſſary in addition to the reduction for longitude, which will be additive if the time be after noon, but ſubtractive if it be before.

Example 3. What was the ſun's longitude at Port Royal on May 4th, 1794, at $5^h\ 30^m$?

Sun's long. for noon at Greenwich -	$1^s\ 14^\circ\ 9'.9$
Hourly mot. $2^m\ 25^s.1$ & long. W. $5^h\ 7^m\ 2^s$ +	12.4
Hourly mot. $2^m\ 25^s.1$ and $5^h\ 30^m$ P.M. +	13.3
Sun's long. at Port Royal at $5^h\ 30^m$	1 14 35.6

Problem III.

To find the ſun's declination for any given time and place from the Nautical Almanac.

Rule, (from W. Wales, F.R.S.) Take the ſun's declination out of the Nautical Almanac for noon at Greenwich on the given day, if the given time be leſs than twelve hours, but for the day following if it be more.

Enter Table VI. of the *Requiſite Tables* with the time from the neareſt noon at the top, and the day of the month in one of the ſide columns: under the former, and oppoſite to the latter ſtands the correction of the ſun's declination on account of the time.

If the ſun's declination be wanted for noon at any other place than Greenwich, enter the table with the longitude of the given place at the top, and the day of the month in one of the ſide columns, againſt which, and under the longitude, ſtands the correction of the ſun's declination on that account.

If the declination be wanted at any other place than Greenwich, and at any other time but noon, both corrections muſt be applied; and they muſt be added to, or ſubtracted from, the declination for noon at Greenwich, according to the directions which ſtand at the top of the column, where the day of the month is found.

Example 1. Find the ſun's declination for $21^h\ 17^m$ apparent time at Greenwich, May 4, 1793?

May 4th at $21^h\ 17^m$ is $2^h\ 43^m$ before noon on the 5th.	
Sun's declination for noon, May 5th	$16^\circ\ 27'\ 34''$ N.
$2^h\ 43^m$ before noon gives - -	− 1 59
Sun's declination, May 4th, at $21^h\ 17^m$ =	16 25 35 N.

Example 2. What was the ſun's declination on the 14th of October, 1793, at $7^h\ 43^m$ in longitude 83° eaſt?

Sun's declination, October 14th, at noon	$8^\circ\ 25'\ 26''$ S.
$7^h\ 34^m$ after noon in Table VI. give	+ 6 54
83° Eaſt longitude in Table VI. give	− 5 3
Sun's declination at $7^h\ 34^m$ in long. 83° eaſt	8 27 17 S.

PROBLEM IV.

To convert sidereal into mean solar time, and the contrary.

Rule. Collect the numbers expressing the acceleration of sidereal on mean solar time out of our Table I. when sidereal time is given to be changed, but the numbers out of Table II. when mean solar time is given; then in the former case subtract the amount from the time given, but in the latter add the said amount, and the difference or sum, as the case may be, will be the time converted into that of a different name.

Example 1. Let it be required to convert $10^h\ 16^m\ 30^s$ of sidereal time into a corresponding quantity of mean solar time?

The work is this:

From Tab. I. 10^h——1^m	$38^s.30$	acceleration of sidereal on mean solar time.
16^m——0	2.62	
30^s——0	0.08	
Amount 1	41.00	

then $10^h\ 16^m\ 30^s - 1^m\ 41^s = 10^h\ 14^m\ 49^s$ the corresponding quantity of mean solar time.

Example 2. Let it again be required to convert $10^h\ 14^m\ 49^s$ of mean solar time into a corresponding quantity of sidereal time?

The operation is thus:

From Tab. II. 10^h——1^m	$38^s.56$	retardation of solar compared with sidereal time.
14^m——0	2.30	
49^s——0	0.14	
Amount 1	41.0	

Then, $10^h\ 14^m\ 49^s + 1^m\ 41^s = 10^h\ 16^m\ 30^s$ which is the corresponding quantity of sidereal time agreeably to Example 1, to which this is the converse.

PROBLEM V.

To compute the sun's right ascension for a given hour at any given place.

Rule, (according to the Requisite Tables.) Take the sun's right ascension in time from page II. of the Nautical Almanac for the given day, and see how much it differs from that of either the preceding or following day, which call the *daily variation* in right ascension in time; with this as an argument, enter Table XXIII. at the top, and with the *time from noon,* or the *difference of longitude,* or both separately and successively, as a second argument for the side of the page, enter the same Table, and the intersection or intersections will give the quantity or quantities to be added to the right ascension for noon at Greenwich, if the time be after noon, or the longitude west, but to be subtracted if the time be before noon, or the longitude east.

Example 1. Required the right ascension of the sun at Bombay, on the 1st of January 1794, at $3^h\ 36^m$?

Sun's Right Asc. Jan. 1, 1794, at Greenwich, per Nautical Almanac	-	18^h	49^m	38^s
Ditto, on Jan. 2	-	18	54	2.8
Daily variation	-		4	24.8
Then ☉'s R. Asc. at noon at Greenwich being	-	18	49	38
Reduction for $3^h\ 36^m$ with $4^m\ 24^s.8$	+		0	40
Reduction for long. of Bombay $4^h\ 30^m\ 32^s$ E.	—		0	50
Right Asc. required	-	18	49	28

Example 2. Let it be required to ascertain the sun's right ascension at 7 o'clock, civil time, in a ship, the longitude of which is 8° 30′ or 34^m E., on April the 20th, 1794?

☉'s R. Asc. on April 19, 1794	-	1^h	50^m	6.2^s
Ditto, — on Do. 20, 1794	-	1	53	49.6
Daily variation	-		3	43.4
Then R. Asc. on April 20, 1794		1	53	49.6
Reduction for 5 hours before noon	—		0	46.5
Reduction for 34^m E.	—		0	5.7
Right Ascension required	-	1	52	57.4

Instead of Table XXIII. of the Requisite Tables, published by the Board of Longitude, Table XVIII. of Dr. Mackay may be used in the solution of this problem.

PROBLEM VI.

To ascertain mean solar time by a sidereal clock or watch: and also sidereal time, from a solar clock or chronometer, on any given day in the year.

Prefatory Remark. A sidereal clock or watch goes faster than a solar one by $3^m\ 55^s.91$ of solar time, and consequently shows one day in the year more than a solar clock or chronometer does, the sidereal day being measured by the earth's absolute rotation as it is referred to a fixed star, and the solar by the earth's synodic rotation, as it relates to the sun in motion. But the right ascensions, or angular distances from the first point of Aries, of all the heavenly bodies, when they are given in time instead of degrees, are given in sidereal time; therefore a clock so regulated as to gain $3^m\ 55^s.91$ per day, if it does not vary in its rate, will always show the right ascension of any star, as it passes the middle wire or hair of a transit instrument, well fixed in the meridian, and levelled, provided the hands of the clock be put to $24^h\ 0^m\ 0^s$ at the instant that the point $12^s\ 0°\ 0'\ 0''$ of the equator, or first point of Aries, is passing the said wire or hair. Hence a sidereal clock, as Mr. Kelly has observed in his Appendix to his "Nautical Astronomy," may with propriety be called a *right ascension clock,* and is that which is usually fixed in observatories, and known by the appellation of an *astronomical clock.* The writer of the present article is in possession of a chronometer, by the late Mr. Margetts, which indicates both mean solar and sidereal time, and consequently the sun's mean right ascension, which is their difference on any day; the manner in which both these kinds of times are indicated by the same machine will be explained under the article DIAL-*work.*

Rule. When sidereal time is given on any day to find the corresponding solar, take the sun's right ascension for the noon of that day and place, by the last problem, and subtract it from the sidereal time given, after borrowing 24^h if necessary, and the remainder will be the sidereal time elapsed since the last apparent noon; to this remainder apply the acceleration of sidereal on mean solar time, from Table I. as already directed in Problem IV., and then the sidereal time will be converted into mean solar time that has passed since apparent noon, to which apply the equation of time *at noon,* and then there will be the mean time elapsed since mean noon, that

that is, there will be the mean solar time. On the contrary, when mean solar time is given, the correspondng sidereal time is found by reversing this operation.

Example 1, (from Mr. Kelly.) Required the mean time on the 8th of September, 1805, when the sidereal clock was at $15^h\ 20^m\ 7^s$?

Time per sid. clock - -		15^h	20^m	7^s
$\odot$'s R. Asc. at noon -		11	5	59 .6
Sid. time elapsed since ap. noon		4	14	7 .4
Accel. of sid. on sol. time from Tab. I.	—	0		41.63
Mean time elap. since ap. noon		4	13	25.77
Equation of time at noon -	—		2	24 .0
Mean solar time -		4	11	1.77

Operation reversed. Example 2, (from Mr. Kelly.) Required the time by a sidereal clock at $4^h\ 11^m\ 1^s.77$ of mean solar time, on the 8th of September, 1805?

Mean solar time given -		4^h	11^m	$1^s.77$
Equation of time at noon, add here	+		2	22
Mean solar time since appar. noon		4	13	25.77
Retardation of solar compared with sidereal time from Table II. -	+			41.63
Sidereal time since apparent noon		4	14	7 .4
Sun's right asc. at apparent noon		11	5	59 .6
Time by sidereal clock -		15	20	7

These examples suppose the clock to be at Greenwich, but if the sidereal time or solar time given is for any other meridian, the sun's right ascension, and also the equation of time, as given in the Nautical Almanac, must be previously reduced to the noon of that meridian, by the respective foregoing problems.

Problem VII.

To take the transit of a celestial object.

Rule. Place the transit instrument in the meridian, and see that all the adjustments are properly made, then when the object to be observed approaches the meridian, elevate the telescope to the required altitude by means of the graduated circle and spirit level at the end of the axis. The sun or star will soon appear in the field of view, apparently moving from the west to the east, when the telescope inverts the object. If there are five wires, or cobweb hairs, which are better, in the focus of the eye-glass, which is usual, mark the time of the transit over each separate wire or hair, as in the subjoined examples, and use a coloured glass over or under the eye-glass if the sun be the object, and the day clear; but if there is but one wire or hair, a simple transit can only be obtained.

Example 1, (from Mr. Kelly's Appendix to his "Nautical Astronomy.") On the 8th of September, 1805, the following transit of the sun was taken at the observatory in Finsbury Square, with a transit instrument of five wires, and a sidereal clock; to find the error of the clock.

1 Wire.	2 Wire.	Mer. Wire.	4 Wire.	5 Wir.	
m. s.	m. s.	h. m. s.	m. s.	m. s.	
3 53.	4 22.5	11 4 52	5 20.5	5 50	$\odot$'s 1st limb.
7 58.5	7 30	11 7 00	6 31.5	6 2	$\odot$'s 2d limb.
					*
11 51.5	11 52.5	22 11 52	11 52	11 52	
		† 51.5			
		52.5			
		52			
		52			
		5 | 260.0			
2		22 11 52			
		11 5 56 mean of the whole.			

* The order of this row of figures is reversed, by which the mean of each column is most readily obtained.

† The hours are inserted in the middle column only, and the other columns may be supposed to contain them.

Hence the $\odot$'s centre passed the meridian at -	11^h	5^m	56^s	per clock.
And per Naut. Alm. $\odot$'s R.A.	11	5	59.6	
Clock slow	0	0	3.6	

The observation might have been made with the middle wire only, by adding the *time of the sun's semi-diameter passing the meridian* (p. 3, Naut. Alm.) to the time when the $\odot$'s first limb passed the third wire; or, by subtracting it from the time of the $\odot$'s second limb passing it; thus,

$\odot$'s 1st limb passed mer. wire	11^h	4^m	52^s	per observation
Times of $\odot$'s semi-diameter passing mer. -		1	4	per Naut. Alm.
	11	5	56	

Or, if $1^m\ 4^s$ be taken from $11^h\ 7^m$, the time of the second limb's passing the meridian wire, the result will be as before.

Example 2. On the evening of the same day, the transit of α Lyræ was thus observed:

First wire	18^h	29^m	7^s	per sidereal clock.
2d ditto		29	43	
Mer. ditto		30	19	
4th ditto		30	55	
5th ditto		31	31	
	5 |	151	35	
Star passed mer. wire	18	30	19	App. R. A. per clock.
Mean R. A. of α Lyræ	18	30	20.05	per Table III.
Corr. for precession and aberra.			+ 2.04	per Tables in the Greenwich observations.
Ditto for nutation, &c.			+ 0.66	
	18	30	22.75	App. R. A. per Tables.
Clock slow	0	0	3.75	

Problem VIII.

To find the rate which a watch goes at by observations of the sun's, or of a star's transit over the meridian.

Rule, (by W. Wales, F.R.S.) *for the sun*. Observe, with a transit-instrument, properly adjusted, the time when the sun passes the meridian of the place every day at noon, (as in the last problem) or as often as opportunities offer. The equation of time must then be taken from the Nautical Almanac, (as in Prob. I.) and, if it be marked additive, it will be the same as the time by the watch when the sun's centre was observed to pass the meridian, if the watch be right. If they differ, that difference is what the watch is too fast, or too slow for mean time: and it is too fast, if the time by the watch be greater than the equation of time; and too slow, if the time by the watch be less. If the equation of time be subtractive, take it from twenty-four hours, compare the observed time when the sun's centre was on the meridian with the remainder, and the difference between them will be what the watch is too fast, or too slow; accordingly, as the time by the watch is the greater or the less. These observations, when the voyage is expected to be of a considerable length, ought to be continued for a month at least: indeed, the longer they are continued, in all cases, the better; but in this the observer must be governed by circumstances. They must always, however, be continued as near as possible to the time when the ship is expected to sail, that there may be as little chance as possible left for the watch to alter its rate of going after the observations are closed.

The times by the watch, when the sun's centre was observed on the meridian, must be written one under another, in column two, against the days of the month when they were observed in column one; and it is the day that began at the instant when the sun's centre was on the meridian, which is to be set before the observed time, and not the day which ended then, as is the custom with seamen. The equation of time, or its supplement to 24 hours, according as it is additive or subtractive, must be set in a third column, against the observed times of noon, and the difference between them in a fourth, with the sign + or —, according as the watch is too fast or too slow for mean time; which difference is had by taking the third column from the second, after borrowing 24, if necessary. This is all that is necessary to be done till all the observations are made.

When the ship is ready to sail, add a fifth column to your paper, take the difference between what the watch was too fast or too slow on the first day of observation, and what it was too fast or too slow on the second, and put it in the fifth column, opposite the space which is between the two numbers of which it is the difference. Take also the difference between what the watch was too fast or too slow on the second day, and what it was too fast or too slow on the third; between what it was too fast or too slow on the third, and what it was too fast or too slow on the fourth, and so on. Place these differences also in the fifth column, opposite the spaces which are between the two numbers of which they are, respectively, the difference. Those differences will be the gain or loss of the watch in the 24 hours, which they respectively stand against. And it must be observed, that the watch is gaining if it be too fast for mean time, and the numbers in the third column increase; or, if it be too slow, and the numbers in the third column decrease; but the watch is losing if it be too fast for mean time, and the numbers in the third column decrease; or if it be too slow, and the numbers in the third column increase.

Remark. By making daily observations in the manner here recommended, it will be seen whether the watch alters its rate of going while it is under trial, which is absolutely necessary to be known; because, if it does, all those observations must be rejected which were made before the alteration happened, and those only retained which were made afterwards.

If no material alteration happened in the rate of the watch's going, during the time of trial, take the difference between what the watch was too fast or too slow on the first day of observation, and what it was too fast or too slow on the last, if they be of the same kind, that is, both too fast, or both too slow; but add them together, if the watch was too fast in one instance, and too slow in the other; this difference, or sum, must be divided by the number of days which elapsed between the first and last day's observations, and the quotient will be the number of seconds and decimal parts that the watch gains or loses in a day. And it is manifest, that if the watch be faster at the end of the trial, than it was at the beginning, it is gaining, and if it be slower, it is losing.

If any considerable alteration happened in the rate which the watch went at, instead of taking the difference between what the watch was too fast or too slow, on the first and last days, take the difference between what the watch was too fast or too slow on the day after that, when the alteration in its rate happened, and what it was too fast or too slow on the day when the last observation was made, and divide by the number of days which elapsed between them. The following examples will make this very plain.

Example 1. Suppose the observed times when the sun's centre passed the meridian of Barbadoes, in the month of December, 1793, were as follow; what was the loss or gain of the watch on mean time?

Note. The days of the week are here denoted, as in the original, by the planetary characters, where ☉ is Sunday, ☽ Monday, ♂ Tuesday, and fo on.

1793.	Obf. Times of ☉'s Tranf.	Mean Time of app. noon.	Watch too faft.	Daily gain.

♂ — 31	4 5 41.9	0 3 52.2	+ 4 1 49.7	

Here it appears that the watch went confiderably fafter the firft three days than it did afterwards; I therefore reject thefe three days, fays Mr. Wales, and take the difference between $4^h\ 1^m\ 4^s.6$, what the watch was too faft on the fourth, and $4^h\ 1^m\ 49^s.7$ what it was too faft on the 31ft, and find it $45^s.1$, which I divide by 27, the number of days elapfed, and the quotient, $1^s.6704$, is the *daily rate*, or quantity which the watch gained on mean time in one day. If the inftrument be not pretty exactly in the meridian, the obferver will, however, by this method, not only get the abfolute quantity of time, which the watch is too faft, or too flow, wrong; but will, if there be any confiderable change in the fun's declination, while the watch is under trial, determine the rate of its going erroneoufly alfo. On this account it will be better to find the rate of the watch by obferving the tranfits of a fixed ftar; the computations being ftill more fimple than they are when the fun is made ufe of, as will be feen in the annexed example.

Example 2. Suppofe the times by a chronometer when the ftar Aldebaran paffed a tranfit-inftrument placed nearly in the meridian of Madras, were as follow: it is required to find how much the watch gained or loft on mean time?

Rule for a ftar. In column one put down the days of obfervation; in column two the obferved times of the tranfit; in column three the differences of each pair of fucceeding times contained in column two; in column four $3^m\ 55^s.91$, the difference between a mean folar and fidereal day; and in column five the differences between the numbers contained in column three and column four with the proper figns, which will be the daily errors in folar time; and laftly, the amount of thefe errors divided by the number of days elapfed will give the mean rate.

The operation according to the Rule.

1794	Obf. Times of the ✳'s Tranf.	Difference.	Diff. bet. m.fol. and fid. day.	Watch gains or lofes on mean Time.	Remarks.
	h. m. s.	m. s.	m. s.	s.	
♀ Jan. 3	9 22 17.42				
♄ — 4	9 18 20.73	3 56.69	3 55.91	−0.78	
☉ — 5	9 14 24.36	3 56.37	3 55.91	−0.46	
☽ — 6	9 10 28.05	3 56.31	3 55.91	−0.40	
♂ — 7	9 6 31.48	3 56.57	3 55.91	−0.66	
☿ — 8	9 2 33.87	3 57.61	3 55.91	−1.70	
♃ — 9	8 58 36.53	3 57.34	3 55.91	−1.43

☉ — 12	8 46 49.46	3 55.61	3 55.91	+0.30	
☿ — 15	8 35 0.17	11 49.29	11 47.73	−1.56	In 3 days
♃ — 16	8 31 4.62	3 55.55	3 55.91	+0.36	
♀ — 17	8 27 8.21	3 56.41	3 55.91	−0.50	

Here it may be obferved, that the fum of all the chronometer's gainings is $4^s.50$, and the fum of all its lofings is $2^s.01$; the difference between them is $2^s.49$, which being divided by 14, the number of days the chronometer was under trial, will give $0''.178$ for the rate or daily gain of the watch.

The rate which a watch goes at is obtained this way with much lefs trouble than by any other; but the *abfolute time* is not given by it, nor, of courfe, how much the watch is too faft or too flow, for mean time, at the meridian it is tried under, which may be found by fome of the following problems.

Problem IX.

To find the rate of a chronometer by comparifon with a good folar or fidereal clock, the rate of which is known, and occafionally corrected.

Prefatory Remark. Though the rate of a chronometer, as afcertained from a fucceffion of tranfits of a heavenly body, be moft to be depended upon, yet it will not always happen particularly in a changeable climate, that a fufficient number of obfervations can be gotten within the limited time allowed for fixing a rate; it will, therefore, be very convenient to compare the going of the chronometer with that of either a folar or fidereal clock, that has a compenfation pendulum and good efcapement, and to afcertain in the mean time the rate of the clock itfelf by occafional obfervations of the fun or ftar, it being generally allowed that a good clock is more fteady in its rate than any chronometer which has yet been made, provided its adjuftments be perfect. It may be advifeable to try the chronometer, in the firft place, in different pofitions, by fhort comparifons of 12 hours each with the clock; and if any confiderable change of rate takes place during fuch fhort comparifons, it muft neceffarily be put into gimbols, or otherwife be fent back again to the maker for new adjuftment for the different pofitions.

Rule

Rule for a solar clock.—Place the chronometer in the position it is likely to preserve in a voyage, and put its hands with thofe of the clock, and have a fheet of paper ruled into as many columns as the comparifon will require; for a solar clock feven columns will anfwer the purpofe, but for a fidereal clock there will be more required. Put titles to the different columns, and, after an interval of each 24 hours, make the requifite comparifons, and enter them as they ftand in the fubjoined example, referving columns four and five to be filled up afterwards; then after as many days' comparifon as the time will allow, complete the calculations in thefe two referved columns thus; take a mean of the obferved differences between the time of the clock and mean time determined occafionally by a tranfit inftrument, which will be the clock's mean daily rate, particularly if the obfervations are taken after equal intervals; then add or fubtract, as the cafe may be, the clock's daily rate to or from the refpective numbers in column three, and fill up column four with the fum or differences, or both, if the cafe fhould fo be; in the next place, take the differences between each couple of the fucceeding lines of column four, and fill up therewith column five, annexing — or +, as the difference may be; laftly, take the difference between the plus and minus amounts, or the fum, if there is but one kind, and divide it by the number of days elapfed on trial, and the quotient will be the daily error, — or +, which error is denominated the *rate*.

Example. Let it be required to affign a rate to a chronometer from the comparifons made in the columns 1, 2, and 3, of the annexed table?

Days of Trial.	Clock after mean Time.	Chrono. diff. from Clock in 24 h.	Do. from mean Time in 24 h.	Daily Rate of Chron.	Mean State of Thermometer.	Mean State of Barometer.
	s	s	s		o	
1	— 6.5	+ 8.5	+ 2.2		54	29.8
2		+ 8.8	+ 2.5	+ 0.3	55	30.0
3		+ 9.4	+ 3.1	+ 0.6	57	30.2
4		+ 7.5	+ 1.2	— 1.9	56	30.4
5		+ 9.0	+ 2.7	+ 1.5	53	29.6
6		+10.4	+ 4.1	+ 1.4	53	29.4
7		+10.5	+ 4.2	+ 0.1	54	29.6
8	— 8.0	+11.3	+ 5.0	+ 0.8	55	29.7
9		+11.5	+ 5.2	+ 0.2	54	29.8
10		+10.4	+ 4.1	— 1.1	56	30.0
11		+10.0	+ 3.7	— 0.4	57	30.4
12		+ 8.4	+ 2.1	— 1.6	58	30.4
13		+ 7.6	+ 1.3	— 0.8	57	30.6
14		+ 7.4	+ 1.1	— 0.2	56	30.5
15	— 4.5	+ 7.2	+ 0.9	— 0.2	57	30.4

$3|\underline{10^{s}}$

Rate of clock $-6^{s}.3$ on an average of 15 days.

— 6.2 Total lofs.
+ 4.9 Total gains.

— 1.3 Diff. in 15 days.

Then $\frac{-1^{s}.3}{15} = 0^{s}.087$ minus is the daily rate of the chronometer taken from a comparifon with the clock for 15 fucceffive days, which rate muft be added to the time fhown by the chronometer on any fucceeding day, after it has been multiplied by the number of days elapfed fince the laft day of the comparifon. This rate might fuffice for a fhort voyage, immediately undertaken, if the chronometer had been tried and approved previoufly; but if not previoufly approved on a voyage, it ought to have a longer trial. If a chronometer could be made fo perfectly as to meafure time precifely alike under all circumftances, a very few days would at any time fuffice for affigning to it its rate. Had not the rate of the clock in this example been taken at equal intervals, it would have been more accurate to have taken a mean between — $6^{s}.5$ and — 8^{s} for the mean rate to be applied for the firft portion, and a mean between 8^{s} and $4^{s}.5$ to be applied to the fecond portion of the trial; particularly as there is a confiderable variation in the rate of the clock. The fame refult might otherwife have been obtained by affigning a daily rate to the clock by interpolation for each feparate day firft, and then by applying each feparate day's rate to each feparate comparifon in column three, to obtain column four, and from that the daily rates of the chronometer in column five; but this method is attended with more trouble, and is only neceffary when the clock's rate is taken at unequal intervals, and is found to vary confiderably. Whenever it happens that the comparifon is not made exactly at the inftant of the 24^{h} being elapfed, the interval, whatever it is, muft be reduced to 24^{h} by proportioning the difference in the going of the two machines correfponding to the faid interval. By the prefent rule alfo the going of one clock may have its rate affigned by a comparifon with that of another.

Rule for a fidereal clock.—When the clock fhows fidereal time, and the chronometer folar, their difference in 24^{h} of folar time ought to be $3^{m}\ 55^{s}.91$ of folar time, but in 24^{h} of fidereal time, $3^{m}\ 56^{s}.55$, provided the machines performed with perfect truth; one or other of thefe two ftandard numbers, therefore, muft be ufed as the meafure of the daily error, accordingly as the interval is a folar or a fidereal day. In making the comparifons previoufly to the calculations being entered upon, it is not neceffary to have more than five columns; one for *the day of the month*, a fecond for *time per watch*, a third for *the time per clock*, a fourth for the *barometer*, and a fifth for the *thermometer;* which form being fo fimple requires no fac fimile. But the calculations, grounded on the data in the faid five columns, require many more columns, for which we fhall not give any previous directions, but infert Dr. Mafkelyne's two methods of arrangement, extracted from "The original Obfervations of the Going of Mr. Harrifon's Watch from day to day," as publifhed by the Board of Longitude; which methods will be better underftood from the forms of his tables, than from any verbal rules of ours, which muft neceffarily be complex.

Example, (from "The original Obfervations"). Let it be required, from the data contained in columns 1, 2, and 3, of the fubjoined tables, to determine the rate of Mr. Harrifon's time-keeper, taken on an average of the 11 days trial contained in the table?

First

First Method.—Calculations of the going of Mr. Harrison's Watch from Day to Day.

	Interval of Comparisons.	Watch loses of Clock.	Watch loses of Clock, in 24^h of Watch.	Clock varies from sidereal Time per Day.	Watch loses of sidereal Time of 24^h. of Watch.	Watch gets on mean Time per Day.	Mean state of Thermometer.	Mean state of Barometer.
	The watch in a horizontal position, with the face upwards.

16 17	24 9	3 38	3 36.64	+0.58	3 37.2	19 .3	56	30.1
						11)209 .56		
						19.509		

By a mean of 11 days' comparisons, from May 6th to May 17th, the watch being in a horizontal position with the face upwards, gets at the rate of $19^s.509$ per day upon mean time.

Dr. Maskelyne's explanation. "The first column shews the days of the month; the second, the interval of time, according to the watch, between the attested comparisons of the watch each day with the transit clock; the third column contains the quantity of minutes and seconds which the watch loses of the clock in the said interval; the fourth column shews how much the watch should lose of the clock in 24 hours of the watch, according to the proportion expressed in the second and third columns; the fifth column gives the daily gaining or losing of the transit clock with respect to sidereal time, as deduced from the observed transits of the fixed stars over the meridian, the sign + being set down in case of the clock's losing, and — in the case of its getting. This correction, applied to the numbers of the fourth column, produces the sixth column, or the losing of the watch from day to day; with respect to sidereal time, in 24 hours of the watch. The seventh column gives the daily gaining of the watch upon mean time, and is found by taking the difference of the preceding column and $3^m\ 56^s.5$ sidereal time, gaining so much upon mean solar time in 24 hours of mean time; or rather more exactly, in 24 hours of the watch, which generally corresponds to less than 24 hours of mean time by near 20 seconds. The eighth column contains the mean state of the thermometer for the day; and the ninth and last column shews the mean state of the barometer." ("The Original Observations," p. xxvii. and xxviii.)

Second Method.—Comparisons of Mr. Harrison's Watch with Mean Time.

	Observed Transit of Sun per Clock.	Time per Clock at comparison with Watch.	Apparent Time.	Equation of Time.	Mean Time.	Time per Harrison's Watch at comparison with Clock.	Harrison's Watch fast for Mean Time.
1766.	h. m. s.	h. m. s.	h. m. s.	m. s.	h. m. s.	h. m. s.	m. s.
♂ May 6	2 53 30.27	3 39 1	0 45 23.60	3 39 .8	0 41 43.8	0 42 0	0 16.2
☿ 7	2 57 20.50	3 12 34	0 15 11.10	3 45 .0	0 11 26.1	0 12 0	0 33.9
☽ 12	3 16 43.71	3 28 33	0 11 47.38	3 59.32	0 7 48.0	0 10 0	2 12.0
♃ 15	3 28 28.77	3 45 20	0 16 48.47	4 1.10	0 12 47.4	0 16 0	3 12.6
♄ 17	3 36 21.83	4 3 34	0 27 7.68	3 59.47	0 23 8.2	0 27 0	3 51.8

If we include here both the 6th and 17th, there will be 12 days in this calculation, during which the watch gained in the whole $3^m\ 51^s.8$ or $231^s.8$, therefore $\frac{231.8}{12} = 19^s.32$ is the rate on this mode of comparison, which agrees very well with the preceding one calculated on the same period.

Explanation, by Dr. Maskelyne. According to the arrangement in this last Table "the first column contains the day of the month; the second, the observed transit of the sun's centre over the meridian, according to the time of the transit clock; the third column shews the time by the clock, when compared with Mr. Harrison's watch; the fourth, the apparent time at the same comparison; the fifth, the equation of time, which, applied to the numbers in the preceding column,

lumn, gives the mean time contained in the fixth column; the feventh column gives the time fhewn by Mr. Harrifon's watch, when compared with the clock; laftly, the eighth column fhews how much the watch is too faft for mean time each day." ("The Original Obfervations," p. xxxix.)

Problem X.

To find the equation of equal altitudes.

Rule, (by A. Mackay, LL.D. F.R.S. Edin. &c.) Enter Table XXIII. (contained in his "Theory and Practice of finding the Longitude," vol. ii.) with the *interval of time* between the obfervations at the *top*, and the *latitude of the place* of obfervation in the *fide* column, and take out the correfpondent number; take out the number from Table XXIV. anfwering to the *interval of time* and the *fun's declination*; fubtract it from the former, if the latitude and declination are of the fame name, otherwife add them, and find the log. correfponding to the remainder or fum, which fubtracted from the pro. log. of the daily variation of the fun's declination, increafed by 5, the remainder will be the pro. log. of the equation of equal altitudes.

Example. Let the latitude of the place of obfervation be 57° 9′ N.; the interval of time between the obfervations 5^h 17^m; fun's declination 17° 48′ S., and change of declination 16′ 19″½.

Required the equation of correfponding altitude?

No. from Table XXIII. to interval and lat.	= 1782	
No. from Table XXIV. to inter. and declin.	= 284	
Sum - - -	2066 log. fub.	3.3151
Daily variation of declination	16′ 19″.5 p. log. + 5 =	6.0424
Equation of equal altitudes	= 20ˢ.2 p. log. -	2.7273

In the Tables I. and II. of Mr. Wales, and in Tab. XLIII. of Mr. Vince, the arguments at top and fide are "half the interval between the obfervations," and "☉'s longitude."

Problem XI.

To find the errors and rate of a chronometer by equal altitudes of the fun.

Rule, (by A. Mackay, LL.D. F.R.S. Edin. &c.) In the morning, when the fun is more than two hours diftant from the meridian, in thefe latitudes, let a fet of obfervations be taken, confifting, for the fake of greater accuracy, of at leaft three altitudes; which, together with the correfponding times per watch, are to be written down regularly, the time of each obfervation being previoufly increafed by 12 hours. In the afternoon obferve the inftants when the fun comes to the fame altitudes, and write down each oppofite to its refpective altitude. Now, half the fum of any two times, anfwering to the fame altitude, will be the time of noon per watch uncorrected; find the mean of all the times of noon, thus deduced from each correfponding pair of obfervations, to which the equation of equal altitudes is to be applied, by addition or fubtraction, according as the fun is receding from, or approaching to, the elevated pole; the fum or difference will be the time per watch of apparent noon, or the inftant when the fun's centre was on the meridian, the difference between which and noon is the error of the watch for apparent time, and the watch will be faft or flow, accordingly as the time of noon thereby is more or lefs than 12 hours.

If the watch be regulated to mean folar time, it is obvious, that the time of noon found as above, fhould agree with that found by applying the equation of time to noon, according to its fign in the Nautical Almanac. If thefe times do not agree, their difference will be the error of the watch for mean folar time. Inftead of applying the equation of time to twelve hours, it perhaps will be found more convenient to apply it with a contrary fign to the time per watch of apparent noon; and the difference between this time and 12 hours will be the error of the watch.

Example 1. January 29, 1786, in lat. 57° 9′ N. the following equal altitudes of the fun were obferved. Required the error of the chronometer?

Time.	A.M.		P.M.
Alt. = 8° 5′	21^h 35^m 8^s		2^h 55^m 43^s
8 10	- 36 8	- - -	54 42
8 20	- 38 9	- . -	52 41.2
8 25	- 39 12⅓	- - -	51 38

	21^h 35^m 8^s	21^h 36 8	21^h 38^m 9^s	21^h 39 12.5
	2 55 43	2 54 42	2 52 41.2	2 51 38

Sum - - - - - - - - - -	.8
Time of noon per chronometer uncorrected	12 15 25.2
Equation of equal altitudes, by Prob. X.	20.2
Time per chronometer of apparent noon	12 15 5.0
Chronometer faft for apparent time -	15 5
Time per watch of apparent noon -	12 15 5.0
Equation of time - - - - -	13 29.8
Time per chronometer of mean noon -	12 1 35.2
Chronometer faft for mean time - -	1 35.2

In obferving equal altitudes, it will be found convenient to put the index of the inftrument to a certain divifion, and to wait till either limb of the fun attains that altitude. If the fucceffive altitudes of the fame fet are equidiftant from each other, the mean of the morning obfervations may be compared with the mean of thofe obferved in the afternoon, in order to find the time of noon.

Example 2. April 20th, 1786, in latitude 57° 9′ N. the following obfervations were made, in order to afcertain the error of the chronometer.

		A.M.	P.M.
Alt. = 35° 40′	time p.chr.	21^h 20^m 27^s .5	2^h 37^m 29^s .5
35 45	- -	21 16 .0	36 41 .0
35 50	- -	22 4 .5	35 52 .5
35 55	- -	22 53 .0	35 4 .0
36 0	- -	23 41 .3	34 15 .6
		10 22 .3	29 22 .6

Time

Time per chron. of noon uncorrected	11 58 58.49		
Equation of equal alt.	— 19.53		
Time p. chr. of app. noon	11 58 38.96		11 58 38.96
Chron. slow for app. time	1 21.04	eq.ti. +	1 16.20
Time per chron. of mean noon	-		11 59 55.16
Chron. slow for mean time	- -	-	4.84

Hence, the observations of the two preceding examples being supposed to be made at the times specified, by the same chronometer, its daily rate may be established upon the supposition of an uniform motion, as follows:

January 29th, clock fast at noon		$= 1^m\ 35''.3$
April 20th, clock slow at noon	-	4.8
Interval, 81 days.	Difference	- 1 40.1

Now $1^m\ 40'.1$, div. by 81, gives $1'.236$ for the daily error or rate of the chronometer.

Second method of operation.

Example 3, (extracted from W. Wales, F.R.S.) Admit that on the 25th of August, 1793, the following observations of equal altitudes were made at Quebec, as in the annexed scheme.

Observation.

Thermometer.	Morning.	Afternoon.	Dou. Alt.	Thermometer.	
°	h. m. s.	h. m. s.	° ′	°	
56	19 26 53.9	4 35 43.3	45 00	67	Upper Limb.
	19 30 2.3	4 32 35.7			Lower Limb.
58	20 4 25.6	3 58 14.6	57 30	68	Upper Limb.
	20 7 36.0	3 55 5.0			Lower Limb.

Operation.

Upper Limbs.	Lower Limbs.	Upper Limbs.	Lower Limbs.	
h. m. s.	h. m. s.	h. m. s.	h. m. s.	
28 35 43.3	28 32 35.7	27 58 14.6	27 55 5.0	Afternoon observ.

0 1 18.6	0 1 19.0	0 1 20.1	0 1 20.5	Noon nearly.
+ 18.3	+ 18.2	+ 17.1	+ 17.0	Equa. Tab. I.
— 1.1	— 1.2	— 1.5	— 1.5	Equa. Tab. II. (by Wales).
0 1 35.8	0 1 36.6	0 1 35.7	0 1 36.0	True time of noon by the watch.
			35.7	
			36.0	
			35.8	
			4)143.5	

Time of noon by the chronometer	- -	$0^h\ 1^m\ 35^s.6$
Mean time of apparent noon (Naut. Alm. p. II.)	-	0 1 35 .3
Chronometer too fast for mean time	- -	00 .6

In any case of necessity, the observations of the equal altitudes may be taken in the forenoon of any day, and in the afternoon of the following day, and then the error of the chronometer may be ascertained by a similar process, as it was at the instant of the intermediate midnight. In this example Mr. Wales has added 24 hours to the time of the afternoon observation, and subtracted therefrom the time of the morning observation, the difference being the interval between the observations. We thought it not necessary to give Mr. Wales's rule, as it is very similar to Dr. Mackay's, and as the operation

ration will be sufficiently underſtood from the arrangement of the figures in the table.

Third Method.

Rule, (by Joſeph de Mendoza Rios, Eſq. F. R. S.) The equation (in Table XXXIII. of Mr. Mendoza's "Collection of Tables for Navigation and Nautical Altronomy,") is divided into two parts, and both have for arguments the ſun's longitude, (which muſt be previouſly found by Problem II.) and the interval, or time elapſed, between the obſervations; the firſt part is, beſides, to be multiplied by the tangent of the latitude, or, which comes to the ſame, by the ſine and ſecant, of the place of obſervation. The ſigns at the top of each ſection mark whether ſuch a part muſt be added to, or ſubtracted from the middle-time, in order to have the time of true noon; but the ſigns of the firſt part muſt be changed, if the place of obſervation is in the ſouthern hemiſphere.

Example 4. September 17th, 1789, (civil time) the following obſervations were made by Count de Bruhl, at his obſervatory at Harefield, ſituated in lat. 51° 36′ 9″.

Altitude of ☉'s upper limb.	Times by the Chronometer. Morning.	Times by the Chronometer. Afternoon.
67° 40′	21 42ᵐ 21ˢ.4	2h 0ᵐ 3ˢ.0
68 0	21 44 5.0	1 58 22.0
68 20	21 45 45.5	1 56 39.0
68 40	21 47 29.0	1 54 55.4
69 0	21 49 12.4	1 53 11.0
69 20	21 52 46.4	1 49 41.0
69 40	21 54 31.6	1 47 52.0
70 0	21 58 15.6	1 44 11.2

Sums - -	174 34 26.9	15 4 54.6
Means (div. by 8)	21 49 18.4	1 53 6.8
	25 53 6.8	Interv. (differ.) $4^h\,3^m\,48^s.4$ or 4 4
Sum - -	47 42 25.2	
Middle time (half)	23 51 12.6	

The ſun's longitude was then 5 ſigns 25°: conſequently

	First Part.	Second Part.
For 5 ſigns 25°, and $\begin{cases} 4^h\ 0^m \\ 4\ \ 20 \end{cases}$	$+15^s.53$ $+15.66$	-0.46 -0.45
Differences - - -	0.13	0.01

$$20^m : 0^s.13 :: 4^m : x \left(= \frac{4' \times 0.13}{20} = 0.03\right) \qquad 20^m : 0^s.01 :: 4^m : x \left(= \frac{4' \times 0.01}{20} = 0.00\right)$$

For ſix ſigns 0°, and $\begin{cases} 4^h\ 0^m \\ 4\ \ 20 \end{cases}$	$+15.63$ $+15.76$	0.00 0.00
Difference - - -	0.13	

$$20^m : 0.13 :: 4^m : x \left(= \frac{4' \times 0.13}{20} = 0.03\right)$$

Therefore,

For $\begin{matrix} 5^s & 25^\circ \\ 6 & 0 \end{matrix}$ and $4^h\ 4^m$	$+15.56$ $+15.66$	-0.46 0.00
Differences - - -	0.10	0.46

$$5^\circ : 0^s.10 :: 1^\circ : x\ (= 0.02) \qquad 5^\circ : 0.46 :: 1^\circ : x\ (= 0.09)$$

	First Part.		Second Part.
Thus, for five ſigns 26°, and $4^h\ 4^m$ -	$+15^s.58$	- - -	$-0^s.37$
Log. firſt part - - - -	1.19257		
Log. ſine latitude - - - -	9.89417		
Log. ſecant latitude - - - -	0.20684		
Log. firſt part corrected (ſum) - -	1.29358	- - -	$+19.66$
Equation - - - - - - - - -			$+19.29$
Middle time - - - - - - - -			$23^h\ 51^m\ 12.60$
Time of true noon - - - - - - -			23 51 31.89

To the time of true noon by the chronometer, thus obtained, it is only neceſſary to apply the equation of time, in order to compare the chronometer with equated, or mean time. The equation of time, in the preſent example, is $5^m\ 49^s.5$, ſo that at true noon the mean time is $23^h\ 54^m\ 10^s.5$; and rom hence it reſults, that the chronometer deviated $-2^m\ 38^s.61$ from mean time.

In theſe four examples, the obſerver is ſuppoſed to be in a ſtationary ſituation.

Problem XII.

To find the error of the chronometer by equal altitudes of the ſun, the ſhip being under way.

Rule, (by A. Mackay, LL.D. F.R.S. Edin. &c.) Let ſeveral

several sets of equal altitudes be observed in the morning and afternoon, and from thence find the corrected time of noon, as before, in Prob. XI.; also, let the sun's azimuth be observed, by which, the variation of the compass being applied, the true azimuth at the time of observation will be obtained.

Now, to the constant log. 9.2219 add the proportional log. of the interval of time between the equal altitudes, the hours and minutes being considered as minutes and seconds; the prop. log. of the hourly rate of sailing, the log. co-sine of the ship's latitude, the log. secant of the course, and the log. tangent of the sun's azimuth; the sum, rejecting tens in the index, will be the prop. log. of the correction answering to the change of latitude; and to the sum of the first four logs. add the log. co-secant of the course; the sum, rejecting tens in the index, will be the prop. log. of the change of longitude. The first correction is to be added to, or subtracted from, the time of noon before found, accordingly as the ship's latitude is increasing or diminishing; and the second correction is additive or subtractive, accordingly as the ship's course has been in the eastern or western hemisphere. The result thus deduced will be the time per watch of apparent noon, under the meridian of the first place of observation.

If the two last corrections be applied with a contrary sign, the time of apparent noon, under the meridian of the second place of observation, will be obtained.

The first correction vanishes, if the course made good between the observations is either due east or west; and the second, if the ship sails on a meridian.

Example. August 7th, 1804, equal altitudes of the sun's lower limb were observed, whereof the means were $9^h\ 14^m\ 52^s$ A.M., and $2^h\ 48^m\ 18^s$ P.M. respectively, the corrected azimuth of the sun from the south was $69\frac{3}{4}°$, the ship's course during the elapsed time S.W. by W. at the rate of 8.6 knots per hour, and the ship's latitude and longitude at noon were 39° 18′ N. and 31°24′ W. respectively. Required the error of the watch for apparent noon, under the meridian of the place where the first set of observations was made?

Constant logarithm	9.2219		
Int. of time $= 5^h\ 33^m$ or $5^m\ 33^s$ p. log.	$=$ 1.5110		
Hourly rate of sailing $8^h\ 6^m$ or $8^m\ 36^s$ p. log.	$=$ 1.3208		
Latitude 39° 18′, co-sine	9.8886		
	1.9423	- -	1.9423
Course 3 points, secant	0.0801	co-secant -	0.2553
Azimuth 69° 45′, tangent	0.4331	sec. cor. $1^m\ 9^s$ P.L.	2.1976
First correction $0^m\ 38^s$ p. log.	2.4555		

Mean of morning set - -		$9^h\ 14^m\ 52^s$
——— afternoon set - -		2 48 18
Uncorrect time of noon - -		12 1 35
Equation of equal altitudes	+	7
Equation of latitude - -	—	38
Equation of longitude -	—	1 9
Time p. watch of apparent noon, under meridian of first place of observation -		11 59 55
Watch slow for apparent time		5
Equation of time - -		5 23
Watch slow for mean time -		5 28

The problem may otherwise be performed, by estimating how many minutes the sun is higher or lower, in consequence of the change of latitude in the elapsed time, at the instant it will attain the corresponding altitude in the afternoon, and setting the index of the quadrant accordingly. This quantity may be found with sufficient accuracy from a traverse table.

Problem XIII.

To find the error of a chronometer, by equal altitudes of a fixed star.

Rule, (by A. Mackay, LL.D. F.R.S. Edin. &c.) Let several altitudes, and the corresponding times per watch, of a known star, be observed when in the eastern hemisphere; and when the star is in the western hemisphere, observe the instants when it comes to each of the former altitudes.

Take the mean of each corresponding pair of times, and the mean of these will be the apparent time per watch of the star's transit over the meridian.

From the apparent right ascension of the star, taken from the table, subtract the sun's right ascension, and the remainder will be the approximate time of the star's transit; from which subtract the equation corresponding thereto, and the sun's right ascension obtained by Prob. V., or from Table XVIII. (of Dr. Mackay), and from the same table take the equation answering to the ship's longitude, which must be added, if the longitude is east, but subtracted, if west. Hence the apparent time of the passage of the star over the meridian will be obtained.

Now, the difference between the observed and computed times of the star's transit, will be the error of the watch for apparent time, and which is fast or slow, accordingly as the time by observation is later or earlier than the computed time of the star's transit.

Example. July 4th, 1804, in latitude 35° 48′ S. and longitude 23° 26′ E. the following equal altitudes of Atair were observed. Required the error of the chronometer for apparent time?

	Time per Chronometer.		Altitude.		Time per Chronometer.
	$8^h\ 17^m\ 0^s$	-	27° 23′		$14^h\ 35^m\ 57^s$
	19 16	-	27 40		33 42
	20 12	-	27 55		32 44
	21 54	-	28 12		31 5
	23 16	-	28 30		29 41
	8 25 55	-	28 52		14 27 1
Sum	7 33	-	-	-	10 10
Mean	8 21 15.5	-		-	14 31 41.6
					8 21 15.5
					22 52 57.1
Observed time of transit		-		-	11 26 28.6
Atair's right ascension		-		-	19 41 18
Sun's right ascension at noon, p. N. Al.					8 14 5
Approximate time of Atair's transit					11 27 13
Equation to $8^h\ 14^m$ and $11^h\ 27^m$ Tab. XVIII. —					1 53
Equation to $8^h\ 14^m$ and 23° 26′ Tab. XVIII. +					16
Apparent time of star's transit		-			11 25 36
Apparent time of transit per watch		-			11 26 29
Watch fast		-	-	-	0 0 53^s

In this problem, the observer is supposed to continue in the place during the interval between the corresponding observations, but if the observations are taken on board of a ship under

under way, the equations muſt be applied ariſing from the ſhip's run, according to the directions given and exemplified in the laſt problem, to reduce the time of the tranſit to either of the two places of obſervation; then the difference between this time and the time indicated by the chronometer, when all allowances are made for rate, &c. will be the longitude of the ſaid place. It may be proper to add here, that when the courſe and diſtance made good between the obſervations are given, inſtead of the obſerved interval of time and hourly rate of ſailing, the conſtant log. 1.4771 (= 9.2219 + pr. log. of one minute) is to be uſed inſtead of 9.2219 which is uſed in Prob. XII.

Problem XIV.

To find the apparent time on any given day in a known latitude by one obſerved altitude of the ſun.

Rule, (according to the Requiſite Tables.) From the obſerved altitude ſubtract the dip of the horizon, and the refraction; and to the remainder add the ſun's ſemi-diameter; the ſum will be the true altitude of the ſun's centre. Subtract the natural ſine of the altitude thus corrected, from the natural ſine of the calculated meridional altitude, and to the logarithm of the remainder add the log. ſecant of the ſhip's latitude, and the log. ſecant of the ſun's declination; their ſum, rejecting 20 from the index, muſt be ſought for in Tab. XVI. under log. riſing, and the time correſponding to it is the apparent time from the neareſt noon, when the ſun's altitude was obſerved. Conſequently, if the obſervation be made in the forenoon, the time, thus found muſt be taken from 24 hours, and the remainder will be the apparent time from noon of the preceding day. The parallax in altitude is here diſregarded, as being too trifling to deſerve notice.

Example. July 9th, 1775, about 8 A.M. in latitude 34° 55′ N. longitude 40° W. the altitude of the ſun's lower limb was obſerved to be 36° 49′½; the obſerver's eye being 21 feet above the ſurface of the ſea; what was the apparent time when this obſervation was made?

Refr. (Tab. I.)	1′ 16″	Sun's declin. Naut. Al.	22° 23′ 15″ N	Tab. VI. of Req. Tab.

☉'s true alt.	36 59 39	- - - - -		Nat. ſine -	60181	
					37442	Log. 4.57336

Time from noon on the 9th •	$3^h\ 58^m\ 22^s$	- - - - Log. riſing - - -	4.69362
	24 0 0		
Apparent time on the 8th -	20 1 38	which was required.	

Second Method.

Rule, (by Joſeph de Mendoza Rios, Eſq. F.R.S.) With the ſhip's longitude and the eſtimated apparent time, find, by the Nautical Almanac, the ſun's declination for the moment of the obſervation. (Problem III.)

From the obſerved altitude of the limb, deduce the true altitude of the centre.

From the ſun's declination, conclude the polar diſtance, and add it together with the ſhip's latitude and the altitude; take half the ſum, and the difference between the half ſum and the altitude.

Take the logarithmic co-ſecant of the polar diſtance, the logarithmic ſecant of the latitude, the logarithmic co-ſine of the half ſum, and the logarithmic ſine of the difference. The ſum (with the index reduced to the units) will be the logarithmic verſed ſine of the time from noon (or the ſun's horary angle), when the altitude was obſerved.

The time from noon is itſelf the apparent time, if the altitude was obſerved to the weſt, or in the afternoon; but, if it was obſerved to the eaſt, or in the forenoon, the time from noon muſt be taken from 24^h, in order to have the apparent time of the preceding day.

Example. February 11th, 1792, in latitude 23° 20′ S. and longitude 27° 27′ W., the altitude of the ſun's lower limb was obſerved (to the eaſt) to be 45° 10′ 10″, the obſerver's eye being 14 feet above the ſurface of the ſea. The eſtimated time was then $20^h\ 57^m\ 30^s$ ($8^h\ 57^m\ 30^s$ in the morning by the watch). What is the apparent time at the ſhip, at the moment of the obſervation?

Eſtimated time at the ſhip, Feb. 11th -	$20^h\ 57^m\ 30^s$
Longitude W. 27° 27′ = - - - -	+ 1 49 48
Time at Greenwich - - - - -	22 47 18
The true altitude will be found to be -	45° 21′ 53″

☉'s declin. (by Naut. Almanac) S -	13° 41′ 36″		
Polar diſtance -	76 18 24	L. co-ſec.	0.01252
Latitude -	23 20 0	L. ſec. -	0.03706
Altitude -	45 21 53		
Sum - -	145 0 17		
Half-ſum -	72 30 8	L. co-ſine	9.47804
Half-ſum-alt -	27 8 15	L. ſine -	9.65609
Time from noon	$3^h\ 4^m\ 40^s$	L. verſ. (ſum)	9.18671
Apparent time required - -	20 55 20		

Third Method.

Rule, (by A. Mackay, LL.D. F.R.S. Edin. &c. and others.) Correct the obſerved altitude of the ſun's limb, and reduce the declination to the time and place of obſervation, which, ſubtracted from, or added to 90°, according as the declination and latitude are of the ſame or of contrary names, the remainder or ſum will be the ſun's *polar diſtance.*

Now,

Now, add together the ſun's corrected altitude and polar diſtance, and the latitude of the place of obſervation, and call the difference between half the ſum of theſe and the altitude, the *remainder*.

Then, to the log. co-ſecant of the polar diſtance, add the log. ſecant of the latitude, the log. co-ſine of the half ſum, and the log. ſine of the remainder; half the ſum of theſe will be the log. ſine of an arch; which, being multiplied by 8, will be ſun's diſtance from the meridian in apparent time. Hence, the apparent time of obſervation, and the error of the chronometer will be known.

Example. March 4th, 1804, in latitude 45° 37′ N. and longitude 19° 19′ W. the following altitudes of the ſun's lower limb were obſerved, the height of the eye being 16 feet above the ſurface of the ſea. Required the apparent time of obſervation, and the error of the watch?

Time per watch.	Alt. ⊙'s l. limb.

Time per chronom.	2 55 6		
Chronometer ſlow -	33^s		

Fourth Method.

Rule, (from A. Mackay, LL.D. F.R.S. Edin. &c.) Enter Tab. XXVII. (of Dr. Mackay) with the declination of the object at the top, and the latitude of the place of obſervation in the ſide column; take out the correſponding number, to which prefix the index 4, and add to it the log. ſine of the corrected altitude; find the natural number anſwering thereto, to which apply the number from Tab. XXVIII. by ſubtraction or addition, according as the latitude and declination are of the ſame or of contrary names. Now, find the above difference or ſum in Table XXIX. and the correſponding time will be the diſtance of the object from the meridian.

Example. May 7th, 1803, in latitude 56° 4′ N. and longitude 7° 30′ W. at $4^h\ 37^m\ 4^s$ P.M. per chronometer, the altitude of the ſun's lower limb was 25° 6′ 1″, and height of the eye 18 feet. Required the error of the chronometer for apparent time?

Fifth Method. By Spherical Trigonometry.

If in any ſpherical triangle, P ⊙ Z, P repreſent the pole, ⊙ the ſun, and Z the zenith of the place, then we ſhall have that caſe in ſpherical trigonometry, in which the three ſides of the triangle are given to find the horary angle at P.

Example. Suppoſe the co-latitude, Z P, of London to be 38″ 28′, the co-alt. or zen. diſtance Z ⊙ corrected 43° 40′, and the co-declination or polar diſtance, ⊙ P, reduced to be 66° 52′ 9″, on June 21, 1795, required the horary angle ⊙PZ, and the mean time correſponding?

The work is thus; viz.

Co. lat. -	38° 28′		
Zenith diſtance	43 40		
Polar diſtance	66 32 9″		
2)	148 40 9		
½ ſum	74 20 4½		
½ ſum − Z P =	35 52 4½	ſine -	9.7678374
½ ſum − ⊙ P =	7 47 55½	ſine -	9.1325553
		Co-ar. s. 38° 28′	0.2061683
		Co-ar. s. 66 32 9″	0.0374842
		2)	19.14[illegible]045
		Sine 21° 55′ 5″ =	9.5720226
		2	

43 50 10 = the angle from noon, which converted to time is $2^h\ 55^m\ 20^s$ of apparent time from noon; to which add the equation at the time, which is $1^m\ 25^s.6$, and the ſum $2^h\ 56^m\ 45^s.6$ will be the mean time from noon, which may be either before or after it.

PROBLEM XV.

To find the apparent time at a given place, on any night, by an obſerved altitude of a ſtar.

Rule, (according to the Requiſite Tables.) Subtract the dip of the horizon and the refraction from the obſerved altitude of the ſtar, and let its right aſcenſion and declination for the given year be taken out of the tables; compute its meridian altitude, from the natural ſine of which take the natural ſine of its corrected altitude, and find the logarithm of the remainder. To this logarithm add the logarithmic ſecant of the

the latitude of the ſhip or place, and the logarithmic ſecant of the ſtar's declination; their ſum, rejecting 20 from the index, muſt be ſought for in Table XVI. under *log. riſing*, and the time correſponding to it will be the diſtance of the ſtar from the meridian; which being added to the ſtar's right aſcenſion in time, if the ſtar was weſt of the meridian at the time of obſervation, or ſubtracted from it, if the ſtar was then eaſt of the meridian, will give the right aſcenſion of the mid-heaven. Find the ſun's right aſcenſion in time by Prob. V. for noon at the given place, and ſubtract it from the right aſcenſion of the mid-heaven; the remainder is the eſtimate time.

Enter Table XXIII. again, as in Prob. V. with the eſtimate time and daily variation of the ſun's right aſcenſion, and ſubtract the minutes and ſeconds, thus found, from the eſtimate time; the remainder is the apparent time when the altitude of the ſtar was obſerved.

Example. April 14th, 1780, latitude 48° 56′, N. longitude 66°, W. the obſerved altitude of Aldebaran, weſt of the meridian, was 22° 24½′; the height of the obſerver's eye, above the ſurface of the ſea, 21 feet; what was the apparent time when that obſervation was made?

Num. from Tab. XXIII. ſubt.	0 1 12			
Apparent time	7 47 34			

Second Method.

Rule, (by A. Mackay, LL.D. F.R.S. Edin. &c.) Correct the obſerved altitude of the ſtar, and let its declination and right aſcenſion be reduced to the time of obſervation.

With the latitude of the place, the true altitude, and apparent declination of the ſtar, compute its horary diſtance from the meridian, by any of the methods given in the laſt problem; which being added to or ſubtracted from its right aſcenſion, according as it was obſerved in the weſtern or eaſtern hemiſphere; the ſum or remainder will be the right aſcenſion of the meridian.

From the right aſcenſion of the meridian, increaſed by 24 hours if neceſſary, ſubtract the ſun's right aſcenſion, as given in the Nautical Almanac for the noon of the propoſed day; the remainder will be the *approximate time* of obſervation; from which ſubtract the equation anſwering thereto, and the ſun's right aſcenſion, from Table XVIII. and let the equation from the ſame table, correſponding to the longitude, be added or ſubtracted, accordingly as the ſhip is to the eaſt or weſt of Greenwich, and the reſult will be the apparent time of obſervation. Hence the error of the watch will be known.

Example. December 13, 1804, in latitude 37° 46′ N. longitude 21° 15′ E. a certain phenomenon was obſerved, and at the ſame inſtant the altitude of Arcturus, eaſt of the meridian, was obſerved to be 34° 6′.4; the height of the eye 10 feet. Required the apparent time of obſervation?

Approximate time	16 36 20		
Eq. to long. Tab. XVIII.	+ 16		
Eq. to approx. time	— 3 2		
App. time of obſ.	16 33 34		

In order to attain the greateſt accuracy from obſervations of this kind, ſeveral ſtars ſhould be obſerved, and the error of the watch deduced from each ſtar ſeparately. If an equal number of ſtars be obſerved on each ſide of the meridian, and nearly equidiſtant therefrom, thoſe errors which ariſe from the inſtrument, the ſpheroidal figure of the earth, &c. will by this means be rendered almoſt inſenſible. If the ſhip is under way, during the interval between the obſervations of the different ſtars, and if that interval is conſiderable, it will be neceſſary to reduce the error to the ſame meridian, by allowing for the difference of longitude made good between the obſervations, as in Prob. XII.

Third Method.

Rule, (from Mr. Mendoza's Tables.) Find the right aſcenſion and declination of the ſtar for the given time by the catalogue.

Reduce the obſerved altitude to the true.

With the ſtar's declination and true altitude, and the ſhip's latitude, compute the ſtar's horary angle (or diſtance from the meridian,) when the altitude was obſerved to the weſt, take the ſum of the horary angle and the ſtar's right aſcenſion; when it was obſerved to the eaſt, ſubtract the horary

horary angle from the right aſcenſion, increaſing this by 24^h, if neceſſary; the ſum (deducting 24^h if greater than this quantity) or remainder, will be the right aſcenſion of mid-heaven.

Take out of the Nautical Almanac, the right aſcenſion for noon of the given day; and its variation during the 24 hours which comprehend the time of obſervation.

If the apparent time at Greenwich, at the moment of the obſervation is accurately known, find the ſun's right aſcenſion for that moment; and ſubtract it from the right aſcenſion of mid-heaven (increaſed by 24^h, if neceſſary) and the remainder will be the apparent time at the ſhip required.

If the apparent time at the ſhip is not well known, it will be neceſſary to proceed according to the following rules:

Subtract the ſun's right aſcenſion for noon, from the right aſcenſion of mid-heaven (increaſed by 24 hours if neceſſary); and the remainder will be the approximated apparent time at the ſhip.

With the difference of longitude, find the correſponding time at Greenwich; and take the interval between it and the noon before. Find the proportional part of the variation of the right aſcenſion to this interval; and add it to, or ſubtract it from the approximated time at the ſhip, accordingly as the correſponding time at Greenwich is before or after the ſaid noon; the ſum, or difference will be the time required.

Example. March 1, 1792, at $9^h\ 32^m\ 9^s$, time eſtimated by means of the watch, latitude 28° 7′ north, and longitude 36° 6′ weſt, the altitude of Aldebaran was obſerved (to the weſt) to be 32° 11′ 45″, the obſerver's eye being 16 feet above the ſurface of the ſea: What is the apparent time at the ſhip when the obſervation was made?

The right aſcenſion of Aldebaran for March 1, is (by Table XXV.)			$4^h\ 24^m\ 0^s.6$

Apparent time at the ſhip required -			9 36 47.1

PROBLEM XVI.

To find the longitude at ſea by a chronometer.

Rule, (by W. Wales, F.R.S., &c.) Obſerve the altitude of the ſun's limb, either in the morning or evening, when it is, at leaſt, three points of the compaſs from the meridian, and note the time when it was obſerved by the time-keeper.

Multiply the daily rate of the watch by the number of days which have elapſed ſince that on which the laſt obſervation was made for finding it, and add the product to the time ſhewn by the watch when the ſun's altitude was obſerved, if the watch be loſing, but ſubtract it from that time if the watch be gaining. To the ſum, or remainder, add what the watch was too ſlow, or ſubtract from it what the watch was too faſt for mean time at the place where its rate was found, on the day when the laſt obſervation was made for finding it, and the reſult will be the mean time at the place when the ſun's altitude was obſerved. To this time add the longitude of the place in time, where the rate of the watch was found, if it be weſt; or ſubtract the longitude in time from it, if it be eaſt, and the ſum or remainder will be the mean time at Greenwich.

To this time find the ſun's declination by Problem III. and correct the obſerved altitude of the ſun's limb for the dip of the horizon, refraction, parallax, and ſemi-diameter, with which, the latitude of the ſhip, and the ſun's declination, find the mean time at the ſhip, (by Problem XIV.)

Take the difference between the mean time at the ſhip, and the mean time at Greenwich, and it will be the longitude of the ſhip in time; eaſt, if the time at the ſhip be greater than the time at Greenwich, but weſt if it be leſs.

Example 1. After having found the rate of a chronometer to be gaining $1^s.67$, (as in Example 1 of Prob. VII.) and that it was too faſt for mean time at Barbadoes, on the 31ſt of December, 1793, by $4^h\ 1^m\ 49^s.7$, let us ſuppoſe that on the 4th of February, 1794, in the afternoon, latitude 44° 26′ N. the following obſervations were taken: what was the longitude of the ſhip; the height of the obſerver's eye above the ſurface of the ſea being 21 feet?

Same Problem.

Rule, (by A. Mackay, LL.D. F.R.S. Edin. &c.) Let feveral altitudes of the fun, or of any fixed ftars to be obferved ; and correct the mean altitude as ufual ; with which, the fhip's latitude, and heavenly object's declination, compute the apparent time of obfervation, to which apply the equation of time, reduced to the time and place of obfervation, according to its title in the Nautical Almanac, and hence the mean time of obfervation will be known.

To the mean of the times of obfervation, as fhewn by the chronometer, apply its error and accumulated rate. Hence, the mean time, under the meridian of the place where the error and rate were eftablifhed, will be known : to which apply the difference of longitude in time between the given place and Greenwich, and the mean time of obfervation under the meridian of Greenwich will be obtained. Now, the difference between the time at the place of obfervation and that of Greenwich will be the longitude of the place in time ; and which is eaft or weft, accordingly as the time by obfervation is later or earlier than the Greenwich time.

Example 3. February 3, 1804, being in latitude 15° 48′ N. the mean of feveral altitudes of Spica Virginis, eaft of the meridian was 53° 24′, and that of the correfponding times, $15^h\ 18^m\ 22^s$ per chronometer, which had been fet to mean folar time at Rio Janeiro, December 5th, 1803, and was then gaining $23^s.8$ daily, on mean time. The height of the eye was 16 feet. Required the longitude of the fhip?

In practice, it will be found very convenient to have a table constructed, shewing the error of the chronometer at the noon of every day for several weeks, or during the estimated time of the run to a place where its error and rate can be again settled. To this table a column should be added, containing its hourly rate continued up to 24 hours.

Thus, supposing the daily rate of a chronometer, deduced from a series of observations, was — $4^s.72$, and its error for mean time, May 9, 1820, at noon was $3^m\ 58^s.6$ slow; then we shall have the subjoined table; viz.

Error of Chronometer at Mean Noon.	Hourly Rate.
♂ May 9 Error = $3^m\ 58^s.6$	1 hour = $0^s.2$
☿ — 10 — = 4 3.3	2 — = 0.4
♃ — 11 — = 4 8.0	3 — = 0.6

♄ — 20 — = 4 50.5	12 — = 2.4

In the last three problem, and indeed in all calculations, where the time is ascertained from an observation of the sun's, or of a star's altitude taken at a distance from the meridian, the accuracy of the result will entirely depend on the accuracy of the observation which furnished the data; it is, therefore, of the utmost importance, that the heavenly body should be in a situation, or azimuth line, in which its change of altitude is the greatest possible in a given time; this precise situation in the diurnal or nocturnal arc of any body, depends partly on the latitude of the place of observation, and partly on the object's declination; but, in all the heavenly objects, the situation alluded to, is when they are in the prime vertical; i. e. when they are either due east or due west of the observer; therefore, the nearer the observed object is to the prime vertical, provided it be not too near the horizon, so as to be too much affected by refraction, the more likely will the determined time be to be accurate. Dr. Mackay, in Table XXV. of his "Theory and Practice of finding the Longitude," p. 56, vol. ii., has given us "the altitude to be observed, in order to ascertain the apparent time with the greatest accuracy," which table is very convenient for determining very nearly when any heavenly object is due east or west: his arguments are, at the top "Declination of the sun or star," and at the side "Latitude:"—and since him, Joseph de Mendoza Rios, Esq. has given not only the requisite altitudes, but also the corresponding distances from noon in time in a parallel column, with the same arguments and mode of arrangement, in Table XXVIII. of his valuable and very cheap volume. This volume contains a complete collection of tables for navigation and nautical astronomy, that no navigator should be without. Indeed the commissioners of the Board of Longitude, and the court of directors of the East India company, with a liberality characteristic of the English nation, have enabled the author (who as liberally gives up his right to the benefits of his labours) to give, for we can hardly say sell, to the world the work in question for one third of its real value, as an encouragement to nautical science.

In the sixteen problems, which we have here exemplified, we have confined ourselves to observations of the sun and stars, though we might have extended our examples to the moon and planets also, if we had deemed it necessary; but the results derived from observations of these bodies, moving as they do in eccentric orbits, would have been less certain, as well as the calculations more complex than those we have given, which are our reasons for having omitted them.

Chronometer. A generical term for an instrument to measure time in *Music*. Accordingly a clock, a watch, or a sun-dial, is a *Chronometer*. See the preceding article. There are, however, chronometers constructed purposely to regulate the bars and measures of music; one in particular invented by M. Sauveur, described in his "Principles of Acoustics." It was a pendulum of a particular kind, which he exclusively applied to ascertain the time in the performance of musical compositions. L'Affilard, in his "Principles dedicated to Religious Ladies," placed at the head of all his airs, figures which expressed the number of vibrations of the pendulum, during the performance of each bar.

Rousseau said in his dictionary, 34 years ago, that it was then 30 years since a similar instrument appeared under the title of chronometer, which beat the time itself; but neither the one nor the other has succeeded. Many, however, continues Rousseau, have pretended that it is very much to be wished that such an instrument was completed in order to fix with precision the time of each bar in a piece of music; as, as, by that means, the true original meafure of each compofition would be recorded, without which expedient, it lofes its character; and after the death of the author, it is only by a kind of tradition, very likely to vary and be loft, that the time is known. Old people already complain that the time of many airs is loft; and it is believed that they are performed too flow. This may have come on by degrees, from the characters in prefent ufe, which look much quicker than thofe of a hundred, or indeed of fifty years ago, when demi-femiquavers were feldom ufed, and where there are now only minims, there ufed to be femi-breves, as in *alla breve* time. We are certain from our own memory, that the time of Handel's mufic is often miftaken, and performed fometimes quicker and fometimes flower than under his own direction.

The Encyclopedifts of the prefent time difpute Rouffeau's opinions about fuch an inftrument to regulate the meafure of each bar throughout a piece, which would be too mechanical, and trench on the authority of the leader. It has long been obferved that mufic on a barrel is ftiff, and without that flexibility, feeling, and expreffion, that are given to it by the human hand or voice, though the accuracy of clock-work is proverbial. But though we are equally difturbed by the abufe and bungling ufe of *rallentando;* yet there is a retardation as well as acceleration of time, which is almoft imperceptible, in the execution of particular paffages of *pathos* and of *fpirit* by a great mufician, which fenfibility alone can produce or underftand.

If a chronometer were to beat the time aloud, it would carry us back to mufical infancy; or if the pendulum were to be watched in its ofcillations, it would take the performer's eye from the book, and too much divide his attention. We can therefore only recommend with fincerity, the conftruction of a fmall machine, which might be an appendage to a piano-forte, to afcertain by the vibration of a pendulum the original time in which every movement of a compofition was conceived, as indicated by numerical figns at the beginning of each ftrain, by the compofer himfelf.

CHRONOSCOPE, formed of χρονος, *time*, and σκεπτομαι, *I confider*, a word fometimes ufed for a pendulum, or machine to meafure time. See PENDULUM and CHRONOMETER.

CHRONUS, or CHRONOS, in *Ancient Geography*, a river placed by Ptolemy in European Sarmatia.

CHROSTASIMA, in *Natural Hiftory*, a name ufed by Dr. Hill for all pellucid gems, which have one fimple and permanent appearance in all lights.

Of this kind are the diamond, the carbuncle, the amethyft, the fapphire, the beryl, the emerald, and the topaz.

CHROUET, WARNER, in *Biography*, a phyfician of eminence, in Brabant in Flanders, flourifhed towards the end of the 17th and beginning of the 18th centuries. The work by which he principally diftinguifhed himfelf is his differtation "De trium Oculi Humorum, aliarumque ejus Partium Origine, et Formatione explicata, Leodii, 1688, 8vo." He fhews that the veffels which Nuck fuppofed he had difcovered, and which he called ducts, for conveying the aqueous humour, were branches of the carotid arteries. His experiments, Haller obferves, were made on the eyes of brutes, but the human eye is found to be fimilarly conftructed. He fpeaks but obfcurely of the *membrana pupillaris*, which he fays is wanting in the dog. He defcribes, very well, the cellular ftructure of the vitreous humour, and gives chymical analyfes of the cryftalline and other humours. The work was reprinted in 1691, with ftrictures on the anfwer to it by Nuck. We have alfo by him, "La Connoiffance des Eaux Minérales d'Aix-la-Chapelle, de Chaud Fontaine, et de Spa, par leurs véritables Principes," Leyde, 1714, 12mo. He fhews himfelf, by the analyfes of thefe waters, to have been well fkilled in practical chymiftry. Haller, Elov. Dict. Hift.

CHRUDIM, in *Geography*, a town of Bohemia, and capital of a circle of the fame name, fituated on a river called "Chrudimka;" which circle contains 33 towns. It is chiefly remarkable for a great number of fifh-ponds, and an excellent breed of horfes; 100 miles S.E. of Drefden, and 50 E. of Prague.

CHRUTUNGI, in *Ancient Geography*, the name of a people which formed a part of the Scythians.

CHRYSI, a town of Afia Minor, in the Æolide. Pliny.—Alfo, the name of a fmall ifland, near that of Crete, on the coaft of the Peloponnefus. Pliny.—Alfo, a place in the Troade, called *Sminthium.*

CHRYSÆ-FANUM, a place of Sicily, near the road that paffed from Afforus to Enna.

CHRYSALIS, in *Entomology*, a technical expreffion among the writers on infects during the laft century that has the fame meaning as the more obfolete word aurelia, and is intended to imply what the Linnæan phrafeology denominates the pupa, or middle ftate in which all lepidopterous and moft other infects remain for fome time between the larva or caterpillar form, and the period of their appearance as perfect infects. The word chryfalis is employed by the beft writers, with the exception of Linnæus. Like the term aurelia, it alludes however to the metallic or golden fplendour of the cafe in which the creature is contained while in the pupa ftate, and is confequently applicable only to the pupæ of certain fpecies of the papilio or butterfly tribe, which in this ftate exhibits fuch a fplendid afpect. The term pupa adopted by Linnæus is more generally expreffive, as it implies that the infect like an infant yet remains enveloped in its fwaddling clothes. See AURELIA, ENTOMOLOGY, and PUPA.

CHRYSANTHEMOIDES, in *Botany*, *Ofteofpermum*, Comm. Hort. See OSTEOSPERMUM-*Spinofum*, Linn. *Spinefcens*, Willd.

CHRYSANTHEMOIDES-*Afrum*, Dill. Elth. See OSTEOSPERMUM *moniliferum*.

CHRYSANTHEMUM, (Χρυσανθεμον, Diofcor.) from χρυσὸς, *gold*, and ανθος, *a flower*.) Linn. Gen. 966. Schreb. 1307. Juff. 183. Vent. 2. 546. Gært. 990. (Leucanthemum and chryfanthemum, Tourn.) Clafs and order, *fyngenefia polygamia fuperflua*. Nat. ord. *Compofitæ difcoideæ*, Linn. *Corymbiferæ*, Juff.

Gen. Ch. *Calyx common*, hemifpherical, imbricated; interior fcales larger by degrees; innermoft membranous. *Corol. compound*, radiated; florets of the ray female, ftrap-fhaped; of the difc hermaphrodite, funnel-fhaped, fpreading, the length of the calyx. *Stam.* five, capillary very fhort; anthers forming a hollow cylinder. *Pift.* germ egg-fhaped; ftyle filiform, longer than the ftamens; ftigmas two, obtufe, revolute. *Seed* one to each floret, oblong, not crowned with a marginal rim. *Recep.* naked, dotted, convex.

Eff. Ch. Receptacle naked. Seed without a marginal ring. Calyx hemifpherical, imbricated; fcales dilated at the margin, membranous.

* *Ray white.*

Leucanthema of Tournefort.

Sp. 1. C. *pinnatifidum*, Linn. jun. Sup. 377. Willd. 1. Ait. Kew. iii. 231. (*Matricaria pinnatifida*, Lam. Defrouffeaux in Encyc. 7.) "Stem fhrubby; leaves fmooth, attenuated at the bafe, pinnatifid; fegments gafhed." A fhrub, two feet high. *Root* perennial. *Stem* fhort, rather thick, woody, naked; branches numerous, cylindrical, with a thick a thick foliage above, naked near the bottom, but marked with the scars of fallen leaves. *Leaves* about seven inches long, and three broad, thickly and irregularly set, oval-oblong, narrowing into a petiole at their base, green, smooth, and glossy on both sides. *Flowers* in a loose corymb, furnished at its divisions with slender bractes, smaller than those of C. *leucanthemum*. A native of the island of Madeira. Desroussseaux mentions a variety, C. *lacerum* of some authors, which he thinks may be a distinct species. It is two or three feet high, and forms a less bushy head than the preceding. Its leaves are less, more deeply pinnatifid, with the segments more deeply but less frequently gashed. *Flowers* on long petioles, less numerous on each branch. 2. C. *paludosum*, Willd. 2. Desf. Atl. tab. 238. Poiret. Itin. ii. 241. "Leaves all oblong-wedge-shaped, obtusely serrated; stem diffusely branched." *Root* annual. *Leaves* smooth, deeply serrated; upper ones only three toothed at the tip. *Flowers* resembling those of C. *leucanthemum* solitary, terminating the branches. A native of moist places in the kingdom of Tunis. 3. C. *atratum*, Linn. Sp. 5, excluding Var. β. Mart. 3. Willd. 3. (Bellis alpina major folio rigido, Bauh. Pin.) "Leaves all oblong-wedge-shaped, acutely serrated; stem simple, one-flowered, erect." Willd. *Root* perennial. *Root-leaves* lobed at the tip. *Calyx* with a black margin. Haller judges it not specifically different from C. *leucanthemum*. 4. C. *heterophyllum*, Willd. "Leaves sessile; lower ones linear-lanceolate, serrated; upper ones spatula-shaped." *Stem* ascending, a foot high, erect, simple, one-flowered. *Flowers* resembling those of C. *leucanthemum*, from which, according to Willdenow, who described it from a dried specimen, it differs in the shape of its leaves, and especially in the extreme minuteness of its upper ones. A native of Piedmont. 5. C. *leucanthemum*, great white ox-eye, or ox-eye daisy, Linn. Sp. Pl. 4. Mart. 5. Willd. 5. Eng. Bot. 601. (Matricaria, Lam.) "Leaves embracing the stem, lanceolate, serrated, gash-toothed at the base; stem erect, branched." Willd. "Leaves embracing the stem, oblong, obtuse, gashed, pinnatifid at the base; root-ones inversely egg-shaped, petioled." Dr. Smith. *Root* perennial, somewhat woody, fibrous. *Stems* two feet high, furrowed with red angles, somewhat hairy. *Leaves* deep green, glossy, smooth; upper ones alternate. *Flowers* shewy, large, solitary, terminal; calyx hemispherico-depressed, smooth; scales numerous, imbricated, scarous at the edges; inner ones dilated into a membrane at the tip; florets of the ray three times the length of the calyx, numerous, spreading, elliptic oblong, bitten at the tip, toothed. *Seeds* cylindrical, entirely destitute of a marginal rim, furrowed, black, with white ribs. *Receptacle* convex. A native of dry pastures and meadows in most parts of Europe. It varies much in different situations; hence the discordance of authors with respect to its varieties and kindred species. 6. C. *montanum*, Linn. Sp. Pl. 6. Mart. 6. Willd. 6. (Matricaria montana, Lam. Leucanthemum montanum minus, Tourn. Bellis montana minor, Bauh. Hist.) "Lower leaves petioled, spatula-shaped, serrated; upper ones linear-lanceolate, serrated; stem generally one-flowered." *Root* perennial. Probably only a variety of the preceding. A native of the south of France, Silesia, and other parts of Europe. 7. C. *rotundifolium*, Willd. 7. Waldst. and Kitaib. Pl. Rar. Hung. "Leaves petioled, serrated; lower ones roundish; upper ones egg-shaped; stem one-flowered." A native of the Carpathian mountains. 8. C. *ceratophylloides*, Willd. 8. Allion. Ped. 686. tab. 37. fig. 1. "Leaves pinnatid; pinnæ linear, acute; stem erect, one-flowered." *Root* perennial. *Leaves* alternate, unequally pinnated; pinnæ quite entire. *Flowers* resembling those of C. *leucanthemum*, scales sphacelated. A native of the mountains of Piedmont. 9. C. *graminifolium*, Linn. Sp. Plant. 7. Mart. 7. Willd. 9. Jacq. Obs. 4. tab. 92. (Matricaria graminifolia, Lam. "Leucanthemum gramineo folio, Tourn. Inst. 493. Bellis montana gramineis foliis, Mag. Monsp. 291. Hort. 31. tab. 31.) "Leaves linear, generally quite entire; stem quite simple." *Root* perennial. *Stems* from six to eight inches high, nearly erect, slender, striated, smooth, destitute of leaves near the top. *Leaves* slightly villous; root-ones often a little toothed near the summit. *Flowers* terminal, rather large, solitary; scales of the calyx egg-shaped, elongated, scarious, and blackish at the edges. A native of mountains in the south of France. 10. C. *tanacetifolium*, Willd. 11. (Matricaria tanacetifolia. Lam. Buphthalmum orientale tanaceti minoris folio, Tourn. Cor. 37.) "Leaves pinnated, hairy; pinnæ pectinate-serrated; calyx tomentous. *Root* perennial. *Stem* about two feet high, furrowed, pubescent, especially toward the base. *Leaves* sessile. *Flowers* small; calyx white, with down. A native of the Levant. 11. C. *monspeliense*, Linn. Sp. Pl. 9. Mart. 8. Willd. 12. (Matricaria monspeliensis, Lam. Leucanthemum montanum foliis chrysanthemi, Tourn. Inst. 492.) "Lower leaves palmated; leaflets linear, pinnatifid." *Root* perennial. *Stems* about a foot high, cylindrical, weak, nearly upright, superficially striated, branched, almost smooth. *Leaves* alternate, sessile, green. *Flowers* large, solitary, terminal; florets of the ray white, or slightly tinged with purple; calyx-leaves elongated, divided by a green line, and ending in a dry brown membrane. A native of the south of France. 12. C. *achilleæ*, Linn. Syst. Nat. Mart. 11. Willd. 13. (C. italicum, Linn. Parthenium foliis tenuissimis, achilleæ cæsuris, Mich. gen. 34, tab. 29.) "Leaves twice pinnated; pinnæ oblong, serrated; flowers in corymbs." Willd. *Root* perennial. *Stem* erect, a foot high, somewhat angular, many-flowered. *Leaves* like those of Millefoil, but eight times as large; besprinkled with scarcely conspicuous, prominent dots; with a few white hairs underneath, and ending in a white stiff point. A native of Italy. As the same synonym from Micheli is referred to by Linnæus under both C. achilleæ and C. italicum, and as no other synonym is quoted under either, it seems almost certain that he has, inadvertently, inserted the same plant twice; and was, perhaps, less likely to detect the error, as, notwithstanding the white ray of C. italicum, he was induced to place it among the chrysanthema, on account of the resemblance of its foliage to some of the species of that division. Desroussseaux maintains, that C. achilleæ is nothing more than a variety of C. corymbosum, which is unquestionably a pyrethrum; but as its seeds are not described, we have left it for the present where Linnæus placed it. 13. C. *argenteum*, Willd. 14. (Matricaria argentea, Linn. Spec. Pl. Encyc. Meth. Mart. Chamœmelum orientale incanum, millefolii folio, Tourn. Cor. 37.) "Leaves twice pinnated, hoary; pinnæ acute, generally quite entire; stem one-flowered, simple." Willd. *Root* perennial. *Stems* scarcely a foot high, erect, cylindrical, downy, often simple, almost destitute of leaves near the top, and surrounded at the base with dry scales, which are the remains of the petioles of the fallen leaves. *Leaves* alternate, oval-oblong, rather obtuse; root ones petioled. *Flowers* rather large, terminal; florets of the disk yellow, of the ray white, linear; scales of the calyx egg-shaped, acute, numerous, closely imbricated, blackish at the edges. A native of the Levant. The whole plant is sweet-scented. 14. C. *tricolor*, Willd. 16. Bot. Mag. 508. Andrews Repos. tab. 109. C. carinatum, Schoasb. Pl. Maroc. tab. 6.) "Leaves twice pinnatifid;

tifid; pinnulæ linear, diſtant, recurved; ſtem erect, branched." *Root* annual. *Flowers* highly beautiful; florets of the diſk dark crimſon; of the ray, white with a yellow baſe; outer ſcales of the calyx keeled; inner ones flat, membranous. There is a variety with perfectly yellow flowers. 15. C. *indicum*, Linn. Sp. Pl. 12. Mart. 13. Willd. 17. Bot. Mag. 327. (Matricaria indica, Encyc. Meth. 23. M. ſinenſis, Pluk. Amel. tab. 430, fig. 2. Rumph. Amb. 5, tab. 91, fig. 1. Tſietti-gu, Rheed. Mal. 10, tab. 44.) "Leaves egg-ſhaped, attenuated at the baſe, three-lobed, toothed; ſtem branched." *Stem* ſomewhat woody, two or three feet high, upright, cylindrical, much branched. *Leaves* reſembling thoſe of mugwort, alternate, petioled, ſerrated, upper ſurface deep green, lower ſurface ſoft to the touch, and clothed with a ſlight down; lobes a little gaſhed and toothed; teeth unequal, peduncled, large, mucronate. *Flowers* large, ſolitary, terminating the branches; florets of the diſk yellow: of the ray whitiſh with a tinge of purple; ſcales of the calyx few, concave, rounded, terminated by a ſcarious ſilvery membrane. A native of China, where, and in other parts of the Eaſt, it has been long cultivated, and highly eſteemed for its beauty. A great number of varieties have, in conſequence, been produced, ſingle, ſemi-double, and double, ſometimes the ſize of the palm of the human hand, reddiſh, quite white, yellowiſh, fleſh-coloured, purple, and of every intermediate colour. Though this magnificent plant has been ſo long cultivated in the Eaſt, it does not appear to have found its way to Europe till 1795, when it flowered for the firſt time in Great Britain, in the collection of Mr. Colville, nurſery-man at Chelſea. It appears to be a hardy green-houſe plant, and as the moſt ſpecious varieties have been ſelected, it promiſes to be a laſting ornament to our conſervatories. The Chineſe employ it to decorate their houſes and tables on feſtive occaſions, and are ſaid to prefer thoſe pieces of porcelain on which it is painted. 16. C. *coccineum*, Willd. 10. (Buphthalmum tanaceti folio ampliore, flore magno coccineo, Tourn. Cor. 37.) "Leaves pinnated, ſmooth; pinnæ pinnatifid, acute; peduncle thickened." *Root* perennial. *Stem* furrowed, ſmooth. *Leaves* ſmooth; ſegments of the pinnæ linear, acute. *Flowers* with a large ſcarlet or purple ray; ſcales of the calyx ſomewhat ſphacelated. A native of Iberia.

** *Florets of the ray yellow.*
Chryſanthema, Tourn.

17. C. *pectinatum*, Linn. Sp. Pl. 17. Mart. 16. Willd. 18. (C. pallidum, Bar. Ic. 421. Matricaria pectinata, Encyc. Meth.) "Leaves pinnated, linear, parallel, acute, quite entire; peduncles ſolitary, one-flowered." *Root* perennial. *Stems* very ſhort, thickiſh, proſtrate, creeping. *Leaves* ſmall, pubeſcent. *Flower* on a longiſh peduncle, with an awl-ſhaped leaf or two at the baſe. A native of Spain and Italy. 18. C. *ſegetum*, yellow ox-eye; or corn marigold, Linn. Sp. Pl. 15. Mart. 17. Willd. 19. Curt. Flor. Lond. faſc. 6, tab. 60. Eng. Bot. 540. (Bellis lutea, foliis profunde inciſis, major, Bauh. Pin. 262.) "Leaves embracing the ſtem, glaucous, laciniated near the ſummit, toothed at the baſe." *Root* annual, ſpindle-ſhaped, ſmall. *Stem* one or two feet high, branched, angular. *Leaves* oblong, variouſly toothed or pinnatifid-laciniated, rarely entire. *Flowers* large, terminal; ſcales of the calyx with a broad membranous edge; florets of the ray inverſely heart-ſhaped, ſpreading. *Seeds* furrowed. A common weed in corn-fields, eſpecially on a gravelly ſoil, in various parts of Europe, flowering from June to Auguſt. 19. C. *umbroſum*, Willd. 22. "Leaves ſeſſile, oblong-lanceolate, attenuated at the baſe, pinnatifid, ſerrated; ſtem erect, branched at the baſe." *Stem* a foot high; branches one-flowered. *Leaves* about three inches long; upper ones linear-lanceolate. A native of mount Athos, deſcribed by Willdenow from a dried ſpecimen. 20. C. *coronarium*, garden chryſanthemum, Linn. Sp. Pl. 16. Mart 22. Willd. 23. Gært. tab. 168. (C. foliis matricariæ, Bauh. Pin. 134. C. creticum, Cluſ. Hiſt. 1. 334. Moriſ. Hiſt. 3. tab. 4. fig. 2, 3. Matricaria coronaria, Encyc. Meth.) "Leaves twice pinnatifid, acute, broader near the ſummit; ſtem branched." *Root* annual. *Stem* two feet high or more, herbaceous, cylindrical, ſtriated, ſmooth, erect; branches forming looſe tufts. *Leaves* alternate, embracing the ſtem. *Flowers* large, terminal, ſolitary; ſcales of the calyx imbricated, oblong, obtuſe, very ſcarious at the edges and ſummit. A native of Candia, Sicily, and Switzerland. There is a variety with double flowers, commonly cultivated as a hardy annual in the Engliſh gardens. 21. C. *floſculoſum*. Linn. Sp. Pl. 19. Mart. 23. (Matricaria rigida, excluding var. β. M. grandis. var. β Encyc. Meth. Balſamita ageratifolia β virgata. C. floſc. β Willd. Tanacetum chryſanthemoides, Gært. tab. 165. "Florets all uniform, hermaphrodite." Deſrouſſeaux (Encyc. Meth.) aſſerts that var. β. is a diſtinct ſpecies, and even ſuſpects that two ſpecies are confounded under the original C. floſculoſum. He thus diſtinguiſhes them: 1. Matricaria *rigida* (Chryſanthemum floſculoſum, Linn. excluding var. β. Bellis ſpinoſa, foliis aggerati, Bauh. Pin. 262. Alp. Exot. tab. 326. Moriſ. Hiſt. 3. tab. 9. fig. 16. Balſamita foliis aggerati, Vail. Act. 339. Tanacetum foliis integris rigidis, Hal. Helv.). "Stem ſhrubby; leaves obovate-wedge-ſhaped, toothed; teeth tranſverſe, rigid." *Root* perennial. *Stem* a foot and half high, ſhrubby, branched; branches cylindrical, ſtriated, nearly ſmooth, leafy almoſt to the ſummit. *Leaves* ſeſſile, a little embracing the ſtem, evergreen, egg-ſhaped, narrowed towards the top, edged with ſtiff, ſharpiſh teeth. *Flowers* ſix or ſeven lines in diameter, yellow, terminal; ſcales of the calyx numerous, imbricated, reflexed at the ſummit, ſcarious, and ſlightly torn, Lam. Encyc. *Seeds* crowned on the outer ſide with an erect, concave, toothed, rim. A native of Africa, and the iſle of Candia. 2. M. *virgata* (Cotula grandis, Jacq. Obſ. 4. p. 4. tab. 81. Chryſanthemum diſcoideum, Allion. Flor. Ped. tab. 11. fig. 1.) "Leaves ſerrated; lower ones ſpatula-ſhaped; upper ones linear-lanceolate; branches rod-like." *Root* annual. *Stems* about a foot and half high, herbaceous, ſlender, elongated, cylindrical, furrowed, almoſt deſtitute of leaves towards their ſummits; branches few, upright, one-flowered. *Leaves* ſcattered, tooth-ſerrated, ſmooth; lower ones narrowed into a petiole; upper ones ſeſſile, narrow. *Flowers* terminal; ſcales of the calyx numerous, imbricated in three or four ranks, lanceolate, ſcarcely ſcarious at the edges. A native of the county of Nice. 3. M. *grandis* (Cotula grandis, Linn. Sp. Pl. Chryſanthemum floſculoſum, β, Linn. Mant. 2. 473.). "Stem generally ſimple, thick, very lofty, hairy toward the bottom, with a large flower." *Root* biennial. *Stem* three or four feet high, ſtriated, villous, rough, with ſtrong hairs near the bottom. *Leaves* fleſhy, ſoft to the touch. *Flowers* near three inches in diameter, yellow, terminal. flat. A native of the coaſt of Barbary. All theſe ſuppoſed ſpecies are deſcribed from living ſpecimens. *Obſ.* The want of a ray inconteſtibly excludes them altogether from the Chryſanthemum and the Matricaria of Linnæus, but we have placed them here, partly that they may not be entirely omitted, the Balſamita of Deſfontaines and Willdenow not having been admitted into the ſyſtem, with a diſtinct generic character, when that part of our alphabet went to the preſs; partly becauſe we wiſhed to lay before our readers at one view the original deſcriptions of Deſrouſſeaux; but chiefly becauſe we are by no means ſatisfied with the manner in which theſe plants are diſpoſed of

 by

by Willdenow. His Balfamita ageratifolia is doubtlefs the original Chryfanthemum flofculofum of Linnæus, the Matricaria rigida of the Encyclopedie Methodique; and this appears to be the only one of the three which had fallen under his notice; but from the toothed rim of the germ it is certainly a Tanacetum, as Gærtner has made it, and not a Balfamita. The other two may poffibly belong to Balfamita, fhould that new genus finally prove a legitimate one. We have to lament that, with refpect to this branch of the fubject, we derive no information whatever from the labours of the French botanift.

*** *Dubious fpecies.*

22. C. *japonicum*, Mart. 24. Willd. 24. Thunb. Jap. 321. "Leaves petioled, gafhed at the tip, toothed." *Stem* fimple, erect, ftriated, villous. *Leaves* alternate, oblong, fmooth, green above, pale underneath. A native of Japan. Though Thunberg's fpecimen was without flower, he pronounces it of this genus; but it was furely a wild, rap-at-a-venture guefs. 23. C. *incanum*, Willd. 25. Thunb. Prod. 161. "Stem fhrubby; leaves trifid, tomentous." 24. C. *glabratum*, Willd. 26. Thunb. Prod. 161. "Stem herbaceous; leaves pinnated, fmooth; pinnæ linear." 25. C. *hirtum*, Willd. 27. Thunb. Prod. 161. "Stem herbaceous; leaves twice pinnatifid, hairy; ftem zig zag." The laft three are natives of the Cape of Good Hope. 26. C. *procumbens*, Mart. 27. Lour. Cochin. 499. (Matricaria finenfis, Pluk. Amalth. tab. 430. fig. 3.) "Leaves finuate-gafhed, blunt; ftem procumbent." *Root* perennial. *Stem* three feet high, frequently creeping, flender, much branched. *Leaves* egg-fhaped, fomewhat downy, petioled. *Flowers* fmall; peduncles many flowered, terminal. A native of Cochinchina and China, where it is alfo cultivated in gardens, and has produced many varieties.

Obf. La Marck, and Defrouffeaux, one of his fucceffors in the botanical department of Encyclopedie Methodique, have entirely difcarded the genus Chryfanthemum, and interfperfed its fpecies among thofe of Matricaria; obferving, not without much fhew of reafon, that the membranous termination of a calyx-fcale is a circumftance too minute and too equivocal to be admitted as an effential part of a generic character. We ourfelves, however, have for the prefent retained the Linnæan divifions. It is rather furprifing that thefe excellent naturalifts fhould have paid no attention to the prefence or abfence of a marginal rim at the top of the feed, a difference which has been received by Gærtner as a fufficient generic diftinction. The genus Pyrethrum, whofe feeds have a marginal rim, has accordingly been adopted by Dr. Smith, with his ufual judgment, and has been avowedly taken up from him by Willdenow.

CHRYSANTHEMUM, in *Gardening*, contains plants of the flowering herbaceous annual, perennial, and fhrubby kinds, of which the fpecies cultivated for ornamental purpofes are chiefly the annual garden chryfanthemum, (C. *coronarium*); the late-flowering creeping chryfanthemum, (C. *ferotinum*); the Montpelier chryfanthemum, or ox-eye, (C. *Monfpelienfe*); the corymbed chryfanthemum (C. *corymbofum*); the fhrubby Canary chryfanthemum, or ox-eye, (C. *frutefcens*); and the baftard fhrubby chryfanthemum, (C. *flofculofum*). Of which the firft has a furrowed, leafy, branching ftem, three feet high, with fmooth ftem clafping leaves; pinnas either pinnate or pinnatifid, the end one very large, bifid, with the pinnules fharply gafhed; the peduncles terminating, one-flowered; the flowers of different colours. It is a native of Sicily, &c.

The fecond has a perennial creeping root; the ftem ftrong, branched, erect, fomewhat villofe, three or four feet high; the leaves are feffile, fmooth; on fome plants with many acuminate ferratures beyond the middle; on others very few towards the end only; others, again, quite entire; the flowers on the ends of the branches of a white colour, appearing in September.

The third is an elegant perennial plant, without fcent, very fmooth, and flightly villofe, with erect branching ftems, three or four feet in height; the lower leaves bipinnatifid; upper pinnatifid, one or two at top, quite entire; the flowers large, white, and radiated, like thofe of the fecond fort.

The fourth is perennial, having an erect ftem, from eighteen inches to two or three feet high or more; the leaves alternate; pinnas pinnate to the middle; the fegments fharply toothed; the ftalks are terminated by corymbs of large white flowers. The whole plant is without fmell or tafte, flowering in July and Auguft, and a native of the fouth of France, &c.

The fifth has a fhrubby ftem, near two feet high, dividing into many branches; the leaves are of a greyifh colour, cut into many narrow fegments; the flowers axillary, ftanding upon naked peduncles fingly, and greatly refembling thofe of common chamomile. There is a fucceffion of thefe for a great part of the year, for which it is chiefly efteemed. It is found in the Canary iflands.

The laft is a procumbent ever-green under-fhrub, two feet in height; the leaves obovate, gradually narrowing into the petiole, finuate, toothed, and ftiffifh; the flowers fmall, terminating, folitary, and of a deep yellow colour. It is found at the Cape of Good Hope.

Of this there are varieties with fingle and double flowers, both white and yellow; with fiftular florets, which has the name of quill-leaved chryfanthemum.

Method of Culture. In the firft, or annual kind, the culture may be effected either by feeds or cuttings, but the latter method is the more expeditious, and, of courfe, more commonly practifed.

In the former of thefe modes, the feed fhould be fown in the early fpring months, on a very moderate hot bed, or under hand-glaffes, and continued fo late as the latter end of April, in a funny fituation in the open ground. It may be put in fmall drills, or on the furface, the mould being previoufly made fine and even, and the feed fown thin, and evenly covered in to the depth of nearly half an inch. When the plants are of fufficient growth, as in May, or the following month, they may be planted out fingly in the fituations where they are to flower. A little water fhould be occafionally given, both while in the beds and when planted out, efpecially when the weather is dry in the latter cafe. And, in order to have fine double forts, care fhould be had to remove all the bad flowers from about them as foon as they can be afcertained, leaving only one or two good ones in a place; and to have them fine in pots, they fhould be removed into them as foon as they can be known, with large balls of earth about their roots, a little water being given at the time to prevent their growth being checked.

The latter method is conftantly employed for continuing the double forts, fo that they may blow early in the fucceeding fummer, in which the cuttings of the ftrong fide-fhoots, about three inches long, which have not flowered, fhould be planted in large pots near the tops, not too nearly together, in the early autumnal months, as the latter end of September, a little water being given at the time, the pots being removed into a frame or a green-houfe for protection during the winter, and air freely admitted in proper weather. About the beginning of April they fhould be removed from the pots into the fituations where they are to flower, being planted out fingly. In this culture they flower much earlier than when raifed from feed. But fome fhould always be raifed from feed, in order to afford cuttings to increafe the double forts from, and thereby avoid their degenerating. The feed made ufe of fhould conftantly be collected from the beft and moft full double-flowered plants.

The fecond, third, and fourth fpecies are capable of being increafed increased by sowing the seeds in March in beds of fine mould, in warm sunny situations, or by dividing the roots and planting them out in the autumnal months, when the season is open and rather moist. The plants in the former of these modes should be transplanted into other beds in the latter end of summer, and set out to the distance of ten or twelve inches, in order to be removed in the autumn following into the places where they are to flower and remain.

The fifth and sixth species are easily increased by planting cuttings of the young branches in pots filled with good rich earth any time during the spring or early summer months, proper shade and water being given. When the plants are well-rooted in the beginning of the autumn, they should be removed, and planted in separate pots, and during the winter placed under the protection of a deep garden-frame or green-house.

The plants of the first sort are well suited for ornament in the beds or borders of pleasure-grounds and other places, as they produce many flowers and continue late in the autumn; and though they are annual, when produced from seeds, the cuttings, as has been seen, when planted out in the autumn continue the winter, and flower earlier in the ensuing summer than the plants raised by seed.

The next three sorts are proper for the borders of extensive ornamented grounds, as they produce an agreeable variety a considerable length of time in autumn, and are of a large as well as hardy growth. And the two last are adapted for green-house collections, where they afford variety among other potted plants of similar growth.

CHRYSANTHERINUS Lapis, in *Natural History*, a name given by old writers to a stone famous for its imaginary virtues of preventing children from sicknesses during the time of dentition, by being worn round the neck by way of necklace; we have no farther account given us of it by authors, than that it was a very brittle stone, and not easily worked into form.

CHRYSAORIS, in *Ancient Geography*, a town of Caria, which afterwards assumed the name of Adrias, or rather Idrias.

CHRYSAORUS, a river of Asia Minor, in Lydia.

CHRYSARGYRUM, a tribute formerly levied on courtesans, and persons of ill fame.

Hoffman says, it was paid in gold and silver; whence its name, χρυσος, *gold*, and αργυρος, *silver*.

Zosimus says, that Constantine first set it on foot; though there appear some traces of it in the life of Caligula by Suetonius; and that of Alexander by Lampridius. Evagrius says, Constantine found it established, and had some thoughts of abolishing it. It was paid every four years: some say, all petty traders were liable to it. It was abolished by Anastasius.

M. Godeau thinks the chrysargyrum was a general tribute, levied every four years, on persons of all conditions, rich and poor, slaves and freemen; nay, even on all animals, as low as dogs; for each whereof they paid six oboli.

CHRYSAS, in *Ancient Geography*, a stream of Sicily, which traversed the country of the Assorins, according to Cicero.

CHRYSE, a promontory near the river Lanos, in the country of the Serres. Pliny.—Also, an island placed by Pliny near and on the other side of the river Indus.—Also, a town near Lemnos, consecrated to Apollo. Steph. Byz.—Also, a town of Asia Minor, in Caria.—Also, a promontory of the island of Lemnos, near Ephestias, and opposite to the island of Tenedos. Steph. Byz.—Also, a town of Pontus, mentioned by Sophocles in his tragedy of Philoctetes.—Also, the name given by Ptolemy to the country, called *Aurea* Chersonesus.

CHRYSEI, a people of India, who inhabited the mountains, between the rivers Iomanes and Indus.

CHRYSIPPA, a town of Asia Minor, in Cilicia. Steph. Byz.

CHRYSIPPUS, in *Biography*, celebrated as a philosopher among the Stoics. He was a native of Solis, a town of Cilicia. He is reported to have spent his paternal fortune in the public service, and then to have devoted himself to philosophy. He fixed his residence at Athens, the great seat of learning and science, and became a disciple of Cleanthes, the successor of Zeno. The scholar did not, however, follow implicitly the doctrines of his master, and the natural powers of his mind enabled him to distinguish himself above his contemporaries. Chrysippus possessed a large share of penetration and acuteness; while, at the same time, he was so industrious, that he rarely suffered a day to elapse without writing 500 lines. He had a great talent for disputation, and discovered so much promptitude and confidence in his mode of arguing, as to be charged with a boldness approaching to audacity. He was accustomed to say, "Give me doctrines, and I will find arguments to support them;" and so highly did he think of himself, and of his own talents, that when he was asked by a friend to point out a proper person as preceptor to his son, he mentioned himself, "for," says he, "if I thought any philosopher excelled me, I would myself become his pupil." He never paid any sort of deference to persons of mere rank, and refused to dedicate to great men or princes any of his works. The violence of his temper in vindicating his own opinions, created him many adversaries, particularly among the Epicureans and followers of the sect of Academics. His own friends could not always justify the course which he took, it being so much his practice to take opposite sides of a question, that he not unfrequently raised objections which he knew not how to answer, and thus furnished his antagonists with weapons against himself. Among his most able adversaries was Carneades, who often availed himself of this circumstance, and refuted Chrysippus by convicting him of inconsistency. Plutarch, in his piece "On Stoic Contradictions," has, it is believed, collected most of his examples from the writings of Chrysippus. His skill in sophistry, and particularly the frequent use which he makes of the figure *sorites* is noticed by Persius, who calls it the heap of Chrysippus:

"Inventus, Chrysippe, tui finitor acervi."

It is generally allowed that this philosopher possessed great learning and ingenuity, so much so, as to rank the next to Zeno, yet, from the fragments of his works that have come down to us, it should seem that his discourses abounded more in curious subtleties, and nice distinctions, than in solid arguments and sound reasoning; and it was the prejudice of the party that dictated the encomium, "that if the gods themselves were to hold disputations, they would adopt the manner of Chrysippus." This philosopher has been charged with maintaining doctrines subversive of religion and the interests of morality; there seems, however, to have been little reason for such an accusation, since his mode of life was not only decent but philosophically frugal and temperate. Plutarch affirms, concerning Chrysippus and his master Cleanthes, that when they had filled heaven, earth, the air, and the sea, with divinities, they allowed none of them to be exempt from death, except Jupiter alone, into whom they imagined that all the other deities would at last be resolved. Hence the Stoics have been charged with maintaining

taining that the divine nature is mutable and corruptible, but the inference is not fairly drawn. According to the ftoical fyftem, the inferior deities, which are portions of that divine fire by which all nature is animated, will, in the general conflagration of the univerfe, return to the fource from which they were originally derived, till a general renovation take place. Cicero has borne his teftimony to the true ftoical faith of Chryfippus, "who," he fays, "is efteemed the moft ingenious interpreter of ftoic dreams, and has affembled a numerous band of unknown gods, indeed fo perfectly unknown, that the human mind, though it be capable of forming conceptions of every kind, is unable to frame a conjecture concerning their nature. He fays, that the divine energy is placed in reafon, and in the foul or mind of the univerfe. The world itfelf he maintains to be God, or an univerfal effufion of his fpirit; and afferts, that the fuperior part of this fpirit, which confifts in mind and reafon, is the common nature of things, containing the whole, and every part. Sometimes he fpeaks of God as the power of fate, and the neceffary chain of events; fometimes he calls him fire; and fometimes he deifies the fluid parts of nature, as water and air; and again, the earth, the fun, the moon and ftars, and the univerfe, in which thefe are comprehended, and even thofe men who have obtained immortality." Such were the opinions of Chryfippus, and fuch, it is well known, were the doctrines maintained by the moft eminent of the ftoic fchool; it appears, therefore, very unjuft to brand this philofopher with any other kind of impiety than that which the fect itfelf, of which he was a chief fupporter, gloried in. Chryfippus, by his great induftry, wrote feveral hundred volumes, of which three hundred are faid to have been on logical fubjects, but in all his works, he borrowed freely from the writings of others. What remains of this voluminous author is to be found difperfed in the more celebrated works of Cicero, Plutarch, Seneca, and Aulus Gellius. He died in the 143d olympiad, at the great age of 83. He was a freeman of Athens, and to his memory a ftatue was erected by Ptolemy. Brucker by Enfield.

CHRYSIS, in *Botany*, Reneal Sp. See HELIANTHUS *annuus*.

CHRYSIS, in *Entomology*, a genus of the hymenopterous order of infects, poffeffing the following character. Mouth horny, projecting; jaws advanced, elongated, horny, linear, with a fingle tooth, tip membranaceous and acute; lip tongue-fhaped, linear, and emarginate at the tip; no tongue. Palpi, or feelers, four, advanced, unequal, and filiform. Antennæ fhort and filiform, confifting of twelve (fometimes thirteen) joints, the firft of which is longeft, and ufually fituated near the mouth. Body fhining, gloffy, and partaking of a golden fplendour in general. Abdomen arched, and concave, fometimes flattifh beneath, with a fcale on each fide. Tail moft commonly dentated; fting fomewhat exferted. Wings flat.

The infects of this tribe or genus obtained the name of chryfis, from the extreme brilliancy of their colours, which, in the greater number of fpecies, emulate the luftre of gold, the ruby, beryl, fapphire, and other precious gems. Few of this genus exceed the fize of the common houfe-fly (mufca domeftica), and many are ftill fmaller than that diminutive infect, which renders them pleafing and convenient objects for microfcopical inveftigation. They are very lively in the fun-fhine, about the middle of the day, hover on the wing in a manner fimilar to the bee, and if difturbed fly fwiftly. During the warmer fummer months they are frequently obferved among fruit trees, and efpecially preferring thofe which are raifed againft walls in a fouthern afpect: they occur likewife againft the trunks of decayed trees on the fide moft expofed to the fun; and fometimes among flowers. Thefe brilliant little infects will not allow themfelves to be captured with impunity; they bite hard, and the fting of the female is a formidable weapon compared with the fize of the infect, and capable of inflicting at leaft a painful puncture, if incautioufly taken in the hand. The larvæ of thefe infects have hitherto efcaped the refearch of naturalifts, or have not certainly been afcertained with any degree of precifion; it is only fuppofed, by analogy, their metamorphofes refemble that of wafps. Degeer found one of the fpecies of this genus, his *chryfis micans*, in a refinous nut-gall formed on the pine, and imagined the infect muft have been depofited there in the egg ftate, and undergone its various changes to the larva, pupa, and perfect ftate within the gall (and which gall moft probably originated from the acrimonious puncture of the parent infect), for he found, on examination, at the bottom of the gall, an empty fpinning of a loofe filky texture, enveloping the remains of the pupa cafe which was burft open, as he prefumed, by the chryfis, when it attained its laft and perfect form. He obferved alfo the excrements of a larva, that of the infect beyond doubt, which had effected its efcape. The generic Englifh term, *golden-fly*, is applicable to moft fpecies of the chryfis genus.

Species.

IGNITA. Smooth and fhining; thorax green, abdomen golden, with four teeth at the apex, Linn. Fn. Suec. Fabr. Donov. Brit. Inf.

This infect is one of the moft beautiful and abundant fpecies of the genus throughout Europe. In England it is partially known by the name of red-tailed golden-fly, but it is the whole of the fuperior furface of the abdomen that is of a fine crimfon colour, changeable to gold. The French call it chryfis en flammé.

FASCIATA. Thorax green, with a blue band; anterior part of the abdomen blue, fafciated with violet, golden in the middle; pofterior end red, with four teeth.—*Chryfis fafciata; thorace viridi fafcia cyanea abdomine antice cyaneo-violaceoque fafciato; medio aureo, poftice rubro quadridentato*, Donov. Inf. India.

"This charming infect is a native of Tranquebar, where there is every reafon to believe it is uncommonly rare. The fpecies does not appear to be defcribed by any author. The only fpecimen we are acquainted with, is in the cabinet of fir J. Banks, bart." See our hiftory of Indian infects above referred to.

SMARAGDULA. Shining green; tail with fix teeth, and blue. Fabr. A native of North America.

CALENS. Shining blue; abdomen golden; tail four toothed, and blue. Fabr.

This is the fame fize as the former; the antennæ and tips of the legs are brown. This is an European fpecies; it has been found in Italy, and alfo in Siberia.

SPLENDIDA. Gloffy blue; tail four-toothed, Fabr. Spec. Inf.

"Very fcarce. This is a native of Tranquebar, where it was difcovered by Dr. Koenig. Fabricius defcribes the infect from a fpecimen in the cabinet of fir Jofeph Banks, bart. A variety of the fame fpecies is found in New Holland," Donov. Inf. India; — which work contains the only figure of Chryfis fplendida extant at prefent.

LYNCEA. Shining blue; fecond fegment of the abdomen with a bluifh eye on each fide; fcutel prominent and acute. Fabr.

Inhabits Africa. The head is grooved; the ocellar fpot on each fide the abdomen has a fulvous pupil; tail armed with four teeth; legs green, and black at the ends.

OCULATA.

Oculata. Shining green; an ocellar golden ſpot on each ſide of the abdomen; tail with ſix teeth, and blue, Fabr. Ent. Syſt.

This inſect is diſtinguiſhed for the peculiar brilliancy of its colours, and the very remarkable ocellated ſpot on each ſide the body on the ſuperior ſurface. Fabricius deſcribed it from a ſpecimen in the Bankſian cabinet taken on the coaſt of Malabar. We have received the ſame kind from Bengal. Vide Donov. Inſ. India.

Carnea. Gloſſy; thorax and firſt ſegment of the abdomen green, reſt fleſh coloured; tail ſerrated. Fabr. Sp. Inſ. Inhabits Italy.

The head is of a green colour, lip villous, and ſilvery; thorax rough and pointed each ſide.

Integra. Shining green; abdomen golden; green at the baſe and tip; tail entire. Fabr.

Reſembles Chryſis ignita in general appearance, but is eaſily diſtinguiſhed by its entire tail. It inhabits Spain.

Bidentata. Smooth, ſhining blue; thorax bidentated, and with the two firſt ſegments of the abdomen golden. Fabr. Degeer. Donov. Brit. Inſ. Inhabits Europe, and is taken rarely in England.

Succincta. Smooth, ſhining green; on the thorax a ſcarlet band; abdomen golden, and armed with three teeth. Fabr. Found in the northern parts of Europe.

Lucidula. Smooth, ſhining green; anterior part of the thorax and abdomen golden; tail entire, Fabr. *Sphex nobilis,* Scopoli.

This inſect is of a ſmall ſize; the antennæ are black; wings marked with a marginal black dot. Inhabits chiefly the ſouth of Europe.

Fulgida. Smooth and gloſſy; thorax and firſt ſegment of the abdomen blue, the reſt golden; tail four-toothed, Linn. Fn. Suec.

Inhabits Europe, and is rather larger than Chryſis ignita.

Purpurata. Smooth, ſhining golden; band in the middle of the abdomen and the ſerrated tail purple. Fabr.

Deſcribed by Fabricius as a native of Saxony. The head is ſcabrous, and golden; antennæ fuſcous; thorax ſcabrous, golden, with three duſky purpliſh lines in the middle; legs golden.

Gloriosa. Smooth, golden, and ſhining; head, breaſt, and legs, blue green. Fabr.

Inhabits Barbary. Deſcribed from the cabinet of Desfontaines. The antennæ are greeniſh blue; head green, with the crown golden; abdomen golden beneath; tail entire; legs blue green. This inſect has ſometimes the whole of the head of a golden colour.

Feroida. Smooth, ſhining golden; abdomen beneath deep black. Fabr.

A ſmall inſect, with the head, thorax, and abdomen, golden, glabrous and ſhining; beneath the wings cyaneous; legs black. Inhabits Italy.

Aenea. Glabrous, ſhining golden; antennæ and legs fuſcous. Fabr.

Deſcribed as a native of Saxony from the collection of Hybner; the ſize is ſmall; wings fuſcous at the tip.

Aurata. Glabrous, and ſhining; thorax green; abdomen golden; tail bidentated. Linn. Fn. Suec.

Found againſt walls in Europe.

Regia. Glabrous, ſhining; thorax blue; abdomen golden; tail entire. Fabr. *Veſpa thorace viridi cæruleo, abdomine aureo cupreo, pene inermi.* Geoff. Inſ.

A native of Europe. The head and thorax are blue without ſpots; abdomen ſubgloboſe, golden, ſhining, ſpotleſs, with the tail entire; antennæ black; wings duſky.

Cyanea. Glabrous, ſhining; thorax and abdomen blue; tail with three teeth. Linn.

Veſpa cærulea nitens, Geoffr. Inhabits Europe. This inſect is very common in England, and has nearly the ſame habits as Chryſis ignita. Donov. Brit. Inſ.

Nitidula. Shining green; thorax bidentated behind; tail with four teeth. Fabr.

Deſcribed from the Bankſian cabinet as an American inſect.

Amethystina. Shining green; tail four-toothed, and blue; wings fuſcous. Fabr.

Inhabits New Holland. Size of the laſt. Antennæ fuſcous, and at the baſe green; thorax green; ſcutel prominent and concave; wings duſky.

Cyanochrysa. Glabrous, green-gold; head and thorax blue; tail with four teeth; wings brown. Forſt. Nov. Gen.

This inſect is a native of Spain. Its ſize is rather leſs than Chryſis ignita; wings and tarſi fuſcous.

Cyanura. Glabrous, ſhining green; thorax bidentated; abdomen four-toothed and tipped with blue. Forſt. Nov. Inſ.

Inhabits the ſame country as the preceding. Its ſize is conſiderable; antennæ black; eyes large and of a purpliſh brown colour; two laſt ſegments of the abdomen blue.

Beryllina. Head greeniſh-blue; thorax blue, greeniſh at the anterior part, and bidentated behind; abdomen green and bluiſh with a reddiſh gloſs; legs blue with a teſtaceous dot. Muſ. Leſk. Linn. Gmel. This kind inhabits Europe.

Thalassina. Head green blue, abdomen golden, the laſt ſegments green blue, and armed with four teeth; thorax gold with a ſquare green ſpot in the middle and green behind. Linn. A native of Europe. Muſ. Leſk.

Inermis. Blue; anterior part of the thorax green; abdomen golden and entire. Linn. Muſ. Leſk. A native of Europe.

Chrysorrhousa. Green; laſt ſegment of the abdomen golden and entire. Linn. Inhabits Europe.

Leskii. Green; ſpot before the ſcutel and abdomen green gold, and entire. Linn. An European ſpecies.

Scutellaris. Shining blue; ſcutel and abdomen golden; tail blue. Fabr.

This and the following new ſpecies are deſcribed by Fabricius in his "Supplementum Entomologiæ Syſtematicæ," one of his laſt publications. Chryſis ſcutellaris is a native of Italy, and bears much affinity with Chryſis calens. The head is blue; antennæ black; thorax blue, gloſſed with green; abdomen ſcarcely toothed; legs blue. Deſcribed from the cabinet of Dr. Allioni.

Cærulescens. Glabrous, ſhining, golden purple; antennæ and poſterior part of the thorax black. Fabr.

A native of France, in the cabinet of Boſc. Size and general appearance ſimilar to that of Chryſis ignita; head, thorax, and abdomen, golden purple; thorax beneath the ſcutel black; breaſt and legs blue and ſhining.

Maculata. Glabrous green and ſhining; occipital band, and dorſal ſpots on the abdomen deep black; tail entire. Fabr. Muſ. Boſc.

Inhabits the American iſlands. The head is braſſy green; antennæ black; thorax green with a bluiſh anterior dot; abdomen braſſy, with the black dorſal ſpots large.

Dimidiata. Glabrous, ſhining green; thorax and two firſt joints of the abdomen golden; tail four-toothed. Fabr. Muſ. Boſc.

The head of this inſect is green; antennæ, and vertical ſpot on the head black; thorax golden, with green breaſt.

Sex-dentata. Glabrous, ſhining green; ſegments of the abdomen blue at the baſe; tail with ſix teeth.

An

An infect of fmall fize, the native country of which is unknown. The thorax is green and without fpots.

CHRYSITES, a name given by the ancients to yellow litharge, fuch as we call litharge of gold. We diftinguifh this only in regard to the colour, and fo did the ancient Greeks; but Avicenna, and the reft of the Arabians, have ufed this word only for the name of fuch litharge as was made from gold, or whatever colour it happened to be; the reft they called by the name of Argyrites, as they tell us, whether it was made of filver, copper, or even of the marcafite melted, and refined by lead. See KLIMIA.

CHRYSITRIX, in *Botany*, (from *χρυσος*, *gold*, and θριξ, hair.) Linn. Mant. 304. Schreb. 1610. Juff. 27. Clafs and order, *polygamia diœcia*. Nat. ord. *Calamariæ*, Linn. *Cyperoideæ*, Juff.

Gen. Ch. Hermaphrodite. *Cal.* Glumes bivalved, numerous, imbricated; valves ovate-oblong, clofe, cartilaginous, permanent. *Cor.* Glumes one-valved, chaff-like, very numerous, fafcicled, briftle-fhaped, membranous, coloured, bright, longer than the calyx, permanent. *Stam.* Filaments folitary, in each glume of the corolla, capillary, the length of the glume; anther linear, adnate to the filament below the tip. *Pift.* Germ oblong, obtufe; ftyle filiform, fhort; ftigmas three, long. *Seed* not known. Male, in a diftinct plant, differing in nothing from the hermaphrodite but the want of a piftil. This genus would therefore be placed by Dr. Smith in the clafs Monandria.

Sp. C. *capenfis*. Mart. Lam. Illuft. Pl. 842. *Root* perennial. Stature of Sifyrinchium. *Leaves* about a foot long, fword-fhaped, equidiftant, of an even furface. *Scape* refembling a leaf, compreffed, membranous. *Spathe* terminal, bivalved; one valve ftraight, as if it were a continuation of the fcape; the other lower, egg-fhaped, dehifcent. *Flower* from the upper edge of the fcape, refembling a faftigiate fafcicle of golden briftles, ftraightened by a cartilaginous perianth. Linn. Mant. A native of the Cape of Good Hope.

CHRYSOANA, in *Ancient Geography*, a river of India, on the other fide of the Ganges. Ptolemy.

CHRYSOBALANUS, in *Botany*, (from *χρυσος*, *gold*, and *βαλανος*, a *drupe*, *acorn*, &c.) Linn. Gen. 621. Schreb. 850. Juff. 340. Vent. 3. 352. Icaquier; Encyc. Meth. Clafs and order, *icofandria monogynia*. Nat. Ord. *Pomaceæ*, Linn. *Rofaceæ*, Juff.

Gen. Ch. *Cal.* Perianth one-leafed, bell-fhaped, fmall, five-cleft to the middle; fegments expanding, withering. *Cor.* Petals five, longer than the calyx, oblong, fpreading, inferted by their claws into the calyx. *Stam.* Filaments numerous, forming a circle, erect, the length of the petals, or longer, flattened and villous near the bafe; anthers fmall, didymous, *Pift.* Germ fuperior, egg-fhaped; ftyle the fhape and length of the ftamens, inferted laterally at the bafe of the germ; ftigma obtufe. *Peric.* Drupe egg-fhaped. *Seed*, nut egg-fhaped, a little pointed at the fummit, obfcurely pentagonal, wrinkled, marked with five longitudinal furrows, fomewhat five-valved, containing an oval kernel.

Eff. Ch. Calyx five-cleft. Petals five. Stamens numerous. Drupe fuperior. Nut furrowed, fomewhat five-valved. Lam.

Sp. C. *icaco*, Linn. Sp. Pl. Mart. Lam. Willd. Jacq. Amer. tab. 94. coloured fig, tab. 141. Lam. Illuft. Pl. 428. (Icaco, Plum. Guajeru, Marcgr. Bras.) An irregular fhrub, eight or ten feet high; branches cylindrical, fmooth, with a brown or ruffet bark, befprinkled with whitifh minute fpots. *Leaves* two inches long, and about one and a half broad, turning brown or blackifh when dried; alternate, egg-fhaped, obtufe, entire, emarginate; fmooth on both fides, coriaceous, veined, on fhort petioles. *Flowers* fmall, whitifh, a little villous or cottony on the outfide without fmell; racemes branched, loofe, a little fhorter than the leaves, axillary and terminal; peduncles a little angular, compreffed; bractes fcale-like, fmall, acutely egg-fhaped, villous, caducous. *Fruit* about the fize and nearly the fhape of a damafcene plumb, either quite entire, or with five, fix, or feven grooves; fkin very thin; pulp in fmall quantity, adhering firmly to the nut, the confiftence of a baked apple, with little fmell, and a fweet fomewhat auftere, but not unpleafant tafte. A native of South America and the Weft Indies, in fituations not far remote from the fea, where it continues in flower almoft the whole year, but generally ripens its fruit in June and December. The fruit is moft commonly yellowifh, or a kind of ruffet white; but is found red, purple, violet, and nearly black; fome of which, on farther examination, may not improbably prove diftinct fpecies. In its native climate, it is fold commonly in the market, and is eaten either raw or preferved in fugar. Its root paffes for an aftringent, and has been employed as fuch in medicine.

CHRYSOBERYL. Oriental or opalefcent chryfolite of the *Jewellers*. The colour of this mineral is afparagus green, paffing into greenifh white on one fide and on the other through olive-green into yellowifh grey, and fometimes reddifh-brown. It generally exhibits a bluifh milky light, undulating within the cryftals. It is ufually met with in fmall rounded pieces, but occafionally poffeffes a well marked cryftalline figure. Its primitive form is a rectangular parallelepiped, but it is alfo found in fhort regular hexahedral prifms either with or without a truncated hexahedral pyramid at each extremity of the prifm. The furface of the rounded pieces is fomewhat rough, and generally reflects glittering variegated colours. The cryftals poffefs a double refraction, are externally fhining, and very brilliant internally, fo that when polifhed it is fometimes miftaken for the yellow diamond. The fracture of chryfoberyl is perfectly conchoidal: its fragments are indeterminate, angular, and fharp-edged: its hardnefs is fuperior to that of quartz; its fp. gr. is 3.7.

It is infufible *per fe* before the blowpipe. It confifts, according to Klaproth, of

Alumine	71.5
Silex	18
Lime	6
Oxyd of Iron	1.5
	97.0

It is procured chiefly from Brazil, where it accompanies topaz. It has alfo been difcovered in fand from the Ifland of Ceylon, together with rubies and fapphires. A few fpecimens have been brought from Nertfchinfk in Siberia. It is however, upon the whole, a rare mineral, and from its hardnefs and luftre is confiderably valued by jewellers.

CHRYSOCERI, in *Antiquity*, a defignation given to oxen defigned for facrifices. They were fo called from their horns being gilded.

CHRYSOCOLLA, in the *Materia Medica of the Ancients*, the name of a fine green arenaceous powder, properly one of the faburræ, and found on the fhores of the Red Sea, on thofe of fome parts of America, and in Ruffia; and that found at this time has all the properties of that mentioned by the ancients. It ferves to the foldering of gold and other metals, and, given internally, is a violent and dangerous emetic.

It is of a very elegant colour, ferments violently with aqua fortis, and is wholly diffolved by it, and tinges it with a bluifh green; and, being calcined, it lofes all its green colour.

Chryfocolla is reprefented by Pliny as found in mines of gold, filver, copper, and lead: its colour, he fays, was various, according to that of the matter in which it is found; yellow, if among gold, white in filver, green in copper, and black in lead. The Arabs and inhabitants of Guzuratte, call the modern chryfocolla, which is borax, tincar or tincal. The beft is that found in copper-mines; and the worft, in thofe of lead.

CHRYSOCOLLA is alfo the name of a fort of precious ftone, mentioned by Pliny, lib. xxxvii. cap. 10, who calls it alfo *amphitane*. He defcribes it as of a gold colour, and of a fquare figure; adding, that it has the virtue of attracting iron, and even gold. But this, in all probability, is fabulous; and the ftone he fpeaks of is apparently no other than the cubic pyrites.

CHRYSOCOMA, in *Botany*, (χρυσοκομη, Diofc. from χρυσος, *gold*, and κομη, *the human head of hair*, alfo *the bufhy top of trees and herbs*.) Goldy-locks. Linn. Gen. 939. Schreb. 1275. Juff. 180. Vent. 2.512. Gært. 967. Clafs and order, *fyngenefia polygamia æqualis*. Nat. ord. *Compofitæ difcoideæ*. *Corymbiferæ*, Juff.

Gen. Ch. *Cal. common*, hemifpherical, imbricated; fcales linear, outwardly convex, acuminate. *Cor.* florets hermaphrodite, tubular, funnel-fhaped, numerous, equal; border five-cleft, revolute. *Stam.* filaments five, very fhort; anthers forming a hollow cylinder. *Pift.* germ oblong, crowned; ftyle filiform, fcarcely longer than the florets; ftigmas two, oblong, depreffed, involute. *Peric. common*, the permanent calyx. *Seeds* folitary, ovate-oblong, compreffed; down fimple. *Recep.* naked, flat.

Eff. Ch. Receptacle naked. Down fimple; calyx hemifpherical, imbricated. Style fcarcely longer than the florets. Willd. Calyx hemifpherical or egg-fhaped, of a moderate fize, imbricated; fcales oblong, externally convex, florets all androgynous, pitted, rough with the toothed-edges of the cavities. Down fimple, often-toothed, rough. Gært.

* *Shrubby*.

Sp. 1. C. *comaurea*, Linn. Sp. Pl. 2. Mart. 2. Willd. 1. "Leaves linear, ftraight, fmooth, decurrent from the back." *Stem* about a foot high, woody; branches numerous, fmall. *Leaves* narrow, deep green, fcattered, with a fhort appendage on the back part, which runs along the petiole. *Flowers* yellow, terminal on flender naked peduncles. A native of the Cape of Good Hope. It is cultivated in our green-houfes, chiefly on account of its continuing in flower the greater part of the year. 2. C. *patula*, Linn. Mant. 280. Mart. 5. Willd. 2. "Somewhat fhrubby; leaves linear, fmooth; branches divaricated." *Stem* compound, branches growing by threes or fours, much divaricated, fmooth. *Leaves* obtufe, fpreading. *Flowers* terminal, folitary, fcarcely peduncled. A native of the Cape of Good Hope; nearly allied to the preceding, differing chiefly in its much divaricated branches, and fcarcely peduncled flowers. 3. C. *fericea*, Linn. jun. fup. Mart. 3. (Conyza fericea, Willd. 42.) "Silky white; leaves linear, channelled; little branches panicled near the top." Branches, leaves, and peduncles, very white, with filky pubefcence. Little branches fimple, but panicled with flower-bearing tip; fhorter little branches, terminated with a few-flowered panicle. *Leaves* long, flaccid. *Flowers* yellow; calyxes fmooth; fcales yellow, awl-fhaped. It differs from tomentofa in being much whiter; and having fmaller flowers, leaves an inch long, and panicled branches, not one-flowered. A native of the Canary iflands, where the acrid pungency of its bark and wood has recommended it as a cure for the tooth-ache. *Obf.* Willdenow has removed this fpecies to the genus Conyza, but as he has not affigned his reafons, we have left it in its original ftation. Authors, when they make fuch changes, fhould always diftinctly fpecify the grounds of their determination, and fhould carefully refer from the old genus to the new; but to this very obvious rule the Berlin profeffor is altogether inattentive, to the great inconvenience of thofe who confult him; for as his unfinifhed work is without an index, it is often at the expence of not a little time and patience that we find out what he has done with a plant. 4. C. *cernua*, Linn. Sp. Pl. . Mart. 6. Willd. 3. (Coma aurea africana fruticans, foliis Linariæ anguftis, major; Comm. Hort. 2. Tab. 45.) "Somewhat fhrubby; leaves linear, recurved, fomewhat fcabrous; flowers nodding at the time when the anthers difcharge their pollen." A lefs plant than C. comaurea, but branching out in the fame manner. *Leaves* fhorter and a little hairy. *Flowers* not half fo large, of a pale fulphur colour. A native of the Cape of Good Hope. It flowers great part of the year, and ripens its feeds in our climate. 5. C. *microphylla*, Willd. 4. Thun. prod. 142. "Leaves round, recurved, fmooth." A native of the Cape of Good Hope. 6. C. *ciliata*, Linn. Sp. Pl. 4. Mart. 7. (C. ciliaris; Reich. 5. Willd. 5. Coma africana fruticans ericæ folio. Comm. Hort. 2. Tab. 48.) "Somewhat fhrubby; leaves linear, ftraight, ciliated; branches pubefcent." A native of the Cape of Good Hope. 7. C. *montana*, Mart. 4. Willd. 6. Vahl. Symb. p. 70. "Leaves oblong, quite entire, flowers folitary." *Stem* branched; branches round, villous. *Leaves* acute, villous. *Flowers* terminal, outer fcales of the calyx oblong, obtufe, fpreading at the tip; inner ones longer, linear, acute; down ferruginous, the length of the calyx. Found by Forfkal on Mount Horeb. 8. C. *tomentofa*, Syft. Veg. 615. Mart. 8. Willd. 7. "Somewhat fhrubby; leaves and branches tomentous." *Leaves* linear. Native country unknown. 9. *C. nivea*, Willd. 8. (Chyfocoma tomentofa; Jacq. Hort. Schœnb. 2. Tab. 147.) "Leaves linear-lanceolate, tomentous, flat; corymbs terminal, feffile." A native of the Cape of Good Hope. It differs from the preceding in its corymbous flowers, on one-flowered branches. 10. C. *fcabra*, Linn. Sp. Pl. 5. Mart. 9. Willd. 9. (Baccharis, Hort. Clif. Conyza Africana tenuifolia, flore aureo, Dill. Elth. tab. 88. fig. 103.) "Somewhat fhrubby; leaves lanceolate, egg-fhaped, recurved, tooth-ferrated; peduncles pubefcent." An underfhrub, nine or twelve inches high. *Leaves* alternate, narrow, fomewhat hairy. *Flowers* fmall, yellow; in heads at firft roundifh, not rough with hairs, afterwards longer, and contracted towards the end; peduncles long, flender, furnifhed with a few fmall leaves; fcales of the calyx numerous, narrow, green. A native of the Cape of Good Hope; flowering in Auguft and September. 11. C. *denticulata*, Willd. 10. Jacq. Hort. Schreb. 3. tab. 368. "Leaves oblong, attenuated at the bafe, flightly toothed, undulated." Native country unknown.

** *Herbaceous*.

12. C. *undulata*, Willd. 11. Thunb. Prod. 142. "Leaves heart-fhaped, lanceolate, undulated." *Root* perennial. A native of the Cape of Good Hope. 13. C. *purpurea*, Mart. 13. Willd. 12. Forft. Prodromus, n. 286. "Leaves elliptic-lanceolate, fomewhat ferrated, pubefcent; panicle terminal, refembling a corymb. 14. C. *linofyris*, Linn. Sp. 6. Mart. 10. Willd. 13. Gært. tab. 176. (Chryfocome Diofcoridis & Plinii, Col. Ecphr. i. tab. 82. Linofyris nuperorum, Lob. Hift. 223. Ic. tab. 409. Ger. Emac. 553. fig. 9. Ofyris auftriaca, Cluf. Hift. i. p. 325. Linariæ tertium genus, Frag. 358. Linaria, foliofo capitulo luteo, major and minor, Bauh. Pin. 213. L. aurea, Ger. 442—8.) "Leaves linear, fmooth; calyxes loofe." *Root*

Root perennial. *Stems* two feet and a half high, round, ſtiff. *Leaves* cloſely and irregularly ſet, long, narrow, of a pale green colour. *Flowers* in an umbel, bright yellow; peduncles one-flowered, ſlender from the upper part of the ſtem. A native of the temperate parts of Europe. The plant, when handled, yields a fine aromatic ſmell. 15. C. *biflora*, Linn. Sp. 7. Mart. 11. Willd. 14. (After, Gmel. Sib. ii. tab. 82. fig. 1. Conyza, Am. Ruth. 192. "Panicled; leaves lanceolate, three-nerved, dotted, naked." *Root* perennial, creeping, and ſpreading to a conſiderable diſtance. *Stems* numerous, erect. *Leaves* acute, rough. *Flowers* yellow, larger than thoſe of the preceding ſpecies. A native of Siberia. The flowers vary with and without a ray, and are ſaid by Willdenow to be either white or blue. 16. C. *villoſa*, Linn. Sp. Plant. 8. Mart. 12. Willd. 15. (After incanus, Gmel. Sib. ii. tab. 82. fig. 2. Conyza tomentoſa & incana, Amm. Ruth. 190.) "Leaves lanceolate, villous; calyxes cloſe." *Root* perennial. *Leaves* quite entire, hoary, alternate, ſeſſile. *Flowers* yellow, in a ſort of umbel; calyx hairy. *Seeds* ſmall, hirſute, crowned with dun-coloured hairs. A native of Siberia and Hungary.

CHRYSOGONUM, (χρυσογονον, Dioſcor. from χρυσος, *gold*; and γονυ, *the keel, or a joint.*) Linn. Gen. 988. Schreb. 1337. Juſſ. 188. Gært. 1009. Claſs and order, *ſyngeneſia polygamia neceſſaria*, Linn. *Corymbiferæ*, Juſſ.

Gen. Ch. *Calyx common* ſimple, five-leaved; leaves oblong, acuminate, nearly the length of the ray, rough on the outer, naked on the inner ſide, ſpreading. *Corol. compound* radiate; florets of the diſk numerous, hermaphrodite but barren, funnel-ſhaped, five-toothed, erect; of the ray five, ſtrap-ſhaped, oblong, truncated, three-toothed, fertile. *Stam. of the hermaphrodite*, filaments five, very ſmall; anthers forming a hollow cylinder. *Piſt. of the hermaphrodite*, germ very ſmall, abortive; ſtyle briſtle-ſhaped, the length of the floret; ſtigma obſcure; *of the female*, germ larger; ſtyle ſhorter; ſtigmas two, revolute. *Recep.* chaffy, chaff-like ſcales diſſimilar in form; thoſe of the diſk ſimple, linear-oblong, obtuſe, concave, pubeſcent outwards, one to each floret; thoſe of the ray compound, four to each floret, united ſo as to form a proper pericarp; the outer one very large, inverſely egg-ſhaped, convex outwards, concave within, covering the back of the ſeed; the three inner ones narrow, linear-oblong, ſhutting up the aperture of the larger ſcale, ſo that two cover the ſides of the ſeed, and the third its interior part, the whole forming a complete pericarp, which opens as the ſeed ripens. *Seeds* inverſely egg-ſhaped, convex outwards, concave within, marked with two obſolete longitudinal furrows, and crowned with a membranous, top-ſhaped ſcale, about half the length of the ſeed; teeth generally three, but, according to Gærtner, ſometimes ſix.

Eſſ. Ch. Calyx ſimple, five-leaved. Receptacle chaffy; chaff diſſimilar in form. Seeds incloſed in a chaffy five-ſcaled pericarp, and crowned with a ſimple toothed ſcale.

Obſ. In forming theſe characters, we have chiefly followed Gærtner, as correſponding moſt with our own ideas of the ſtructure of the parts of fructification: but that eminent carpologiſt muſt have been guilty of an egregious overſight in twice ſtating the five diſſimilar ſcales to encloſe the germ of the barren florets, firſt at the end of his deſcription of the receptacle, and afterwards in the reference to his figure; a ſtate altogether inconſiſtent with the former part of his own deſcription, as well as in oppoſition to all other authors.

Sp. C. *virginianum*, Linn. Sp. Mart. Willd. Gært. tab. 174. *Leaves* reſembling thoſe of *Lamium purpureum*, or common balm, oppoſite, moderately hairy, on long petioles. *Flowers* gold-coloured, terminal. A native of Virginia.

Chrysogonum *Dioſcoridis*, Raw. It. Rai. Hiſt. See Leontice *chryſogonum*.

Chrysogonum, Linn. Sp. Pl. Ed. 1. See Linnia *pauciflora*.

Chrysogonum, in the *Materia Medica*, is alſo the name of a Syrian plant, called the red turnep, the leontopetalon coſta ſimplici of Tournefort.

CHRYSOLACHANON, in *Botany*, a name by which Pliny, and ſome other authors, have expreſſed the white-garden beet.

CHRYSOLITE, *Peridot* of the French mineralogiſts. The principal colour of this mineral is piſtachia-green paſſing into browniſh olive. It occurs in angular or rounded fragments, or cryſtallized. Its primitive form is a ſtraight priſm with rectangular baſes; it alſo occurs in eight, ten, and twelve-ſided priſms. Its internal luſtre is brilliant and vitreous. Its fracture is perfectly conchoidal; its fragments are indeterminately angular and ſharp edged. It is perfectly tranſparent, and poſſeſſes a double refraction in a remarkable degree. Its hardneſs exceeds that of glaſs. Sp. gr. 3.34.

It is infuſible *per ſe* before the blow-pipe, but with borax forms a tranſparent green glaſs. It has been analyſed by Klaproth and Vauquelin, with the following reſults.

	Klap.	Vauq.
Silex	39	38
Magneſia	43.5	50.5
Oxyd of iron	19	9.5
	101.5	98.0

It is not known with any certainty whence the chryſolite is procured; Upper Egypt is ſaid to be one of the countries which afford it, and a few come to the jewellers of Europe from the Eaſt Indies. It ranks among the gems, but its ſoftneſs and unattractive tone of colour, eſpecially when the yellow predominates, render it of little value.

Chrysolite is alſo a general name which the ancients gave to all precious ſtones, wherein the yellow, or golden, was the prevailing colour.

When the ſtone was green, they called it *chryſopraſus*: the

the red and blue too had their particular denominations, which expreffed their colour: the gold being fignified by chryfo; which ftill began the name.

We know but few of thefe chryfolites now: or rather, they are referred to the fpecies of ftone which they approach the neareft to: the green to the emerald, the red to the ruby; and fo of the reft.

Chrysolite *pafte*. The way of making an artificial chryfolite pafte is this: take of prepared cryftal two ounces, ordinary red lead eight ounces; mix thefe well together, and add crocus martis made with vinegar, twelve grains: mix all together; put them into a crucible, lute it over, and bake the whole for twenty-four hours, or longer, in a potter's kiln, and it will produce a very elegant refemblance of the true chryfolite.

CHRYSOLORAS, Manuel, in *Biography*, a learned Greek, the firft profeffor of his language in modern Italy, was born at Conftantinople of noble Roman parents, whofe anceftors are fuppofed to have migrated with Conftantine the Great. It is uncertain in what year he came into Italy. It is, however, well afcertained, that, on occafion of the fiege of Conftantinople by the Turks in 1393, the emperor Manuel Paleologus fent him and other envoys and orators to implore the compaffion and affiftance of the weftern princes. After vifiting the coafts of France and England, where he obtained fome contributions and more promifes, he returned with the pecuniary aid he had collected. About the year 1396, the city of Florence fent him an invitation to open there a public fchool for the Greek language: with this he complied, and taught with great affiduity and applaufe for three years; when the emperor Manuel himfelf coming to Milan, Chryfoloras left Florence, and went to that city, where he taught Greek. He was in England again with the emperor about the year 1405; after which, he travelled to Rome, on an invitation from Pope Gregory XII., and opened a fchool there. He was employed on various embaffies, and, in 1413, accompanied two cardinal legates to the court of the emperor Sigifmond, in order to determine the place for holding a general council. This was fixed at Conftance; and Chryfoloras was fent thither, either by the emperor Manuel, or by the Pope, and died while he was performing his miffion. He was interred in the Dominican church of that city: his epitaph was written by Guarino, and many tributes of praife were beftowed on him by his fcholars; among the more celebrated of whom were Poggio, Vergerio, Manetti, and Leonardus Brunus Aretinus: of thefe, the laft in fpeaking of his mafter, fays, "On the arrival of Manuel, I hefitated, whether I fhould defert my legal ftudies, or relinquifh this golden opportunity of being introduced to a familiar converfe with Homer, Plato, and Demofthenes? with thofe poets, philofophers, and orators, of whom fuch wonders are related, and who are celebrated by every age as the great mafters of human fcience? Of profeffors and fcholars in civil law, a fufficient fupply will always be found in our univerfities; but a teacher, and fuch a teacher, of the Greek language, if he be once fuffered to efcape, may never afterwards be retrieved. Convinced by thefe reafons, I gave myfelf to Chryfoloras; and, fo ftrong was my paffion, that the leffons which I had imbibed in the day were the conftant fubject of my nightly dreams." A funeral oration was pronounced for him in Venice by Andrea Guiliano. Chryfoloras wrote a Greek grammar in the Greek language, which was fo highly efteemed, that above a century afterwards, it was ufed by Erafmus. He publifhed alfo a "Parallel between ancient and modern Rome," addreffed to John, fon of the emperor Manuel. He had a nephew and difciple, John Chryfoloras, who was his coadjutor, and very eminent in reviving Greek learning in Italy. John lived chiefly in Conftantinople, and died about 1425. Gibbon. Gen. Biog.

CHRYSOMALLOS, in *Ancient Geography*, a name given to Mount Ida, in Crete, according to Strabo.

CHRYSOMELA, in *Entomology*, a genus of coleopterous infects in the Linnæan fyftem, containing many beautiful fpecies. In the larva ftate they feed on the leaves of trees and plants, the pulp and tender parts of which they devour, but reject the fibres; fome kinds infeft the cotyledons only, and are very deftructive. In the perfect, as in the larva ftate, they are found chiefly in woods and gardens. Many of thefe infects are flow in motion, but fome kinds have the pofterior legs formed for leaping. The antennæ of the chryfomelæ are moniliform, or compofed of little globular articulations. feelers fix, thickeft towards the end; thorax marginate; wing-cafes immarginate; body in moft fpecies oval. Gmel. Linn. Syft. Nat.

In the earlier editions of the Linnæan Syftema Naturæ, the generic character of the Chryfomelæ is fomewhat differently defined: to conftitute a Linnæan Chryfomela it was fufficient that the antenna was moniliform, and gradually increafed in thicknefs towards the end, and that the thorax and elytra were immarginate. Linnæus divided them into five diftinct families; namely, 1. Thofe having the body of an oval form. 2. The *Saltatoriæ*, or thofe whofe pofterior thighs are much thicker than the others, and formed for leaping. 3. Thofe with the body cylindrical. 4. Such as have the body oblong, and the thorax broader than the abdomen. 5. Thofe of a flender form, with the thorax of an equal breadth with the abdomen.

Geoffroy, diffatisfied with the genus Chryfomela, as laid down by the Swedifh naturalift, divides the infects of this tribe into feveral diftinct genera, in his "Hift. des Infects." Schaeffer has followed Geoffroy in alterations, and in fome meafure improved the genera; and the fame may be faid of Scopoli, though we think the latter exceptionable in referring feveral of the Linnæan Chryfomelæ to the Coccinella genus, becaufe their antennæ are fcarcely fo long as the thorax, and others to the genus Attelabus, becaufe their thorax is broader than the head and body. Geoffroy divides the Linnæan Chryfomelæ into feven genera: his firft genus, *galeruca*, differs from the other Linnæan Chryfomelæ in the rugofity or roughnefs, and margin of its thorax. His fecond genus is *chryfomela*, and has the thorax fmooth and margined. *Cryptocephalus*, Geoffroy's third genus, confifts of thofe Linnæan Chryfomelæ which have the articulations of the antennæ rather longer than ufual, and the thorax of an hemifpherical form. Thofe which have the thorax cylindrical conftitute his genus *crioceris*. Of his genus *diaperis* he defcribes only one fpecies; the generic character confifts in the articulations of the antennæ being rather larger than common, and appearing to be perfoliated; and the thorax convex and margined. *Altica* is the fixth genus, and comprehends the Linnæan family Saltatoriæ, or thofe whofe pofterior legs are formed for leaping. The laft genus is *melolontha*, thofe having antennæ ferrated, or with lateral appendices like a faw, and placed on the fore part of the head before the eyes. In Geoffroy's arrangement of this tribe of infects we perceive the bafis upon which the Galeruca, Cryptocephalus, Crioceris, and other analogous genera are founded in the more modern fyftem of Fabricius. In the "Entomologia Britannica," the genus Chryfomela is thus defined; antennæ moniliform, and thickeft towards the end; head inferted; thorax and wing-cafes immarginate; body ovate and convex.

 The

The Fabrician genus Chryſomela conſiſts of thoſe inſects which have ſix feelers thickeſt towards the end; the lip horny and entire; and the antennæ moniliform. Theſe correſpond with the Linnæan character of the Chryſomela, but the ſpecies deſcribed by this writer are numerous, and, with a few exceptions, conſiſt of inſects entirely unknown to Linnæus. The works of Panzer, Marſham, and other recent entomologiſts, comprehend likewiſe a great variety of new ſpecies, the principal of which we ſhall proceed to enumerate.

Chryſomela, Fabr. Linn. &c.
Species.

Obscurata. Above duſky-braſſy; thorax very glabrous; wing-caſes with ſcattered dots. Fabr. Suppl. Inhabits Germany. Daldorff.

14-Guttata. Duſky-teſtaceous; wing-caſes with ſix white dots. Fabr. Suppl. A native of the Cape. Lund.

Ebraea. Deep black, gloſſy; wing-caſes white, varied with deep black dots. Fabr. Suppl. Same country and cabinet as the laſt.

Exclamationis. Ovate; thorax and legs ferruginous; body yellow, with nine black abbreviated lines, the exterior one interrupted. Fabr. &c. Inhabits North America. The head is ferruginous, and without ſpots; thorax ſmooth, ferruginous, with the anterior margin pale and ſcutel ferruginous.

6-Notata. Black; thorax and wing-caſes pale, with two black dots. Fabr. Suppl. Muſ. Lund. *Obſ.* The head of this inſect is of a pale colour, varied with black; thorax pale and gloſſy, with two black dots; wing-caſes ſlightly ſtriated, pale, with a pair of black dots in the middle of each; body black; legs pale; thighs with a black dot at the tip.

Cajennensis. Oblong, ferruginous; wing-caſes with four black ſpots, and a black band in the middle. Fabr. Suppl.

The head of this inſect is duſky ferruginous, with frontal line and antennæ black; the thorax oblong, duſky ferruginous and immaculate; wing-caſes ſmooth and ferruginous, with a pair of black ſpots at the baſe; in the middle a black band, and behind two black ſpots.

Marmorata. Oblong, black; anterior margin of the thorax and the wing-caſes yellow, ſpotted with black. Fabr. Inhabits Cayenne. Cuvier.

Sumptuosa. Very gloſſy; head and thorax braſſy; wing-caſes violaceous. Fabr. Found in the iſland of Trinidad. Ryan. Muſ. Lund.

Bulgharensis. Oblong, azure, gloſſy; wing-caſes with ſcattered dots; antennæ fuſcous. Schrank. Inhabits Germany. Deſcribed from the cabinet of Daldorff.

Punctatissima. Ovate; deep black; wing-caſes yellow, with numerous black dots; ſternum cornuted. Olivier, and Fabr. Ent. Syſt. Inhabits Cayenne.

The head is black, with an oblong impreſſed dot in front; thorax black and gloſſy, with the margin a little prominent; wing-caſes very ſmooth; legs black.

Fustulata. Deep black, with five bands of fulvous dots. Fabr. Ent. Syſt. *Erotylus puſtulatus*, Mant. Inſ. A native of Cayenne. Dr. Schulz.

Morio. Ovate, deep black; antennæ and legs black. Babr. Inhabits Van Diemen's land. Bankſian cabinet.

Coriaria. Ovate; deep black; legs entirely violet. Fabr. *Chryſomela laichert*, Auſt. 143. 2. A native of Germany.

Nigrita. Ovate; blue; wing-caſes punctured and more duſky. Fabr. Found in the neighbourhood of Paris. Boſc.

Goettingensis. Ovate; deep black; legs violet, ends rufous. Linn. Inhabits Germany; alſo found in England, but very rarely. Donov. Brit. Inſ.

Hottentotta. Ovate; blue black; antennæ and legs of the ſame colour; wing-caſes irregularly dotted. Fabr. A native of Germany.

Æthiops. Ovate; black, beneath duſky; wing-caſes irregularly dotted. Fabr. Inhabits Germany. Smidt.

Vittata. Ovate; blue; margin and ſtripe along the middle yellow, Fabr. Inhabits America. Schulz.

Bicolor. Ovate; braſſy-green; beneath violet; wing-caſes ſtriated with dots. Fabr. *Chryſomela viriolicærulea*, Forſk.

This inſect inhabits Alexandria; it is entirely of a duſky-greeniſh-braſſy colour above, and has the wing-caſes ſtriated with dots in pairs.

Bankii. Ovate; above braſſy; beneath teſtaceous. Roſs Fn. Etruſ. A native of Europe, and found in England but rarely. Donov. Brit. Inſ.

Ferruginea. Ovate; ferruginous; beneath black. Fabr. Deſcribed as an African inſect from the Bankſian cabinet.

Lusitanica. Ovate; thorax coppery; wing-caſes braſſy, with impreſſed bluiſh dots; beneath violet. Fabr. A native of Luſitania. Bankſian cabinet.

Affinis. Ovate; obſcure-braſſy, beneath violet; wing-caſes ſmooth. Fabr. Found under ſtones in Barbary. Vahl.

Metallica. Ovate; braſſy, ſhining; antennæ and legs teſtaceous. Fabr. Very much reſembles *Chryſomela Bankſii*. Inhabits Germany. Helwig, &c.

Lamina. Braſſy-green; thorax very glabrous; margin thick; wing-caſes ſtriated with dots. Fabr. Inhabits Germany. Smidt.

Gibbosa. Ovate; black; wing-caſes yellow, with two bands and dots at the baſe black. Fabr. A South American ſpecies. The wing-caſes are yellowiſh, with four black dots at the baſe.

8-Maculata. Ovate; duſky ferruginous; wing-caſes with four yellow ſpots on each. Fabr. A native of Surinam.

10-Pustulata. Ovate; black; wing-caſes with five rufous ſpots. Fabr. Deſcribed from the cabinet of Gigot d'Orcy. It is a native of St. Domingo.

Trimaculata. Blue; wing-caſes yellow, with a band and two ſpots of black. Linn. Inhabits South America.

Adonidis. Black; margin of the thorax yellow, with a black dot; wing-caſes yellow; future and ſtripe black. Fabr. *Chryſomela adonidis*, Pallas It. A variety, β, is deſcribed by Fabricius, with the margin of the thorax teſtaceous inſtead of yellow; and the wing-caſes teſtaceous; the marginal dot on the thorax black, and the future and ſtripe on the elytra of the ſame colour as in the firſt-mentioned inſect. Hubner conſiders it as a ſexual difference.

Clavata. Head and thorax ferruginous; wing-caſes black, with a yellowiſh ſtripe. Fabricius deſcribes this from the Hunterian cabinet. Its country is unknown.

Trifasciata. Dull teſtaceous; wing-caſes yellow, with two braſſy-green bands. Fabr. From Surinam.

Suturalis. Teſtaceous, wing-caſes braſſy, with two dots, and two bands of yellow. Fabr. A native of Cayenne. Von Rohr.

Pulchra. Braſſy; wing-caſes yellow; future and ſtripe braſſy. Fabr. Inhabits North America. Bankſian cabinet.

Guttata. Deep black, with a ſinuate band; margin of the wing-caſes and ſix dots of white. Fabr. Inhabits the Cape of Good Hope. Bankſian cabinet.

14-Punctata. Ovate, teſtaceous; wing-caſes yellow, with 16 black dots, two of which are common, or united. Linn. Inhabits the Eaſt Indies. The poſterior thighs are very thick, and ſingle-toothed.

Ignita.

Ignita. Blue, polished, wing-cases brassy; antennæ and ends of the legs fuscous. Fabr.

Described from the cabinet of Dr. Hunter as a native of Cayenne.

Surinamensis. Blue, very glossy; antennæ and ends of the legs fuscous. Fabr. *Chrysomela Americana,* Sulz. This is an insect of large size, and inhabits Surinam.

Asiatica. Ovate, brassy-green, and highly polished; wing-cases blue. Fabr. *Chrysomela Asiatica,* Pallas. Found in the southern parts of Russia.

Graminis. Ovate, green-blue, polished; antennæ and legs of the same colour, Linn. Inhabits Europe, and is found in England. Donov. Brit. Inf.

Bifrons. Ovate, brassy-green; body blue. Fabr. Found on plants in Italy. Dr. Allioni.

Cuprea. Ovate; head and thorax brassy; wing-cases coppery; body deep black. Geoffroy.

This species is a native of Germany. The body, antennæ, and legs are black; head brassy, with the eyes fuscous; margin of the abdomen sanguineous.

Tristis. Ovate, blue; antennæ fuscous. Fabr. Inhabits the south of Europe.

Hemoptera. Ovate, violaceous; ends of the feet and wings red. Linn.

Found on plants in Europe. Geoffroy, &c. and in England, Marsh.

Varians. Ovate, blue (sometimes brassy); antennæ and legs black. Fabr. *Chrysomela varians,* Act. Hall. *Chrysomela Hyperici,* Degeer. Inhabits Saxony.

Violacea. Subrotund, blue; antennæ and legs same colour. Fabr. Inhabits Germany. Smidt.

Centaurii. Ovate, shining coppery; brassy green beneath; legs coppery. Fabr. *Chrysomela centaura.* Herbst. Inhabits Germany.

Tricolor. Ovate, brassy, polished; beneath black; antennæ, vent, and legs ferruginous. Fabr. Inhabits Virginia.

Luteicornis. Ovate, brassy-black; antennæ yellow. Fabr.

Inhabits the islands of South America. Dr. Pflug. The body is entirely of a brassy black colour, polished, and impressed with scattered dots of a small size. A variety of this species has the legs varied with black and yellow.

Semistriata. Ovate, black; wing-cases yellow with a black band in the middle; and the anterior and posterior part streaked with black. Fabr. This is a Brasilian species.

Populi. Ovate; thorax bluish; wing-cases red tipped with black. Linn.

This insect inhabits Europe generally, and destroys the leaves of the ash tree. The larva has six feet, and is varied with black and white, with a double row of tubercles, from which a yellowish unpleasant moisture is exuded. It has been described by many authors, as Degeer, Merian, Albin, Lister, &c.

Tremula. Ovate, bluish; wing-cases testaceous. Geoffroy. Inhabits Europe, and resembles C. *populi,* but is not above half its size, and has the tip of the wing-cases of the same colour.

Grossa. Ovate, blue, polished; wing-cases testaceous, and without spots. Fabr. Inhabits Italy. Dr. Allioni.

Staphylæa. Ovate, and dull testaceous. Linn. Found on plants in Europe.

Fervida. Ovate, testaceous; wing-cases brassy; margin testaceous. Fabr. A native of the island of Java. Dr. Mauduit.

Polita. Ovate; thorax golden; wing-cases testaceous. Linn. Geoffr. Inhabits Europe on the willow.

Lunata. Ovate; ferruginous; margin of the wing-cases, stripe, and lunate in the middle yellowish. Fabr. Described from the Banksian cabinet. The country unknown.

Glabrata. Ovate, testaceous, polished; wing-cases edged with blue. Fabr. Inhabits Surinam.

Lurida. Ovate, black; wing-cases chesnut, with punctured striæ. Linn. Inhabits Europe.

Vittata. Ovate, thorax black and brassy; wing-cases yellow, with nine fuscous stripes. Fabr. Country unknown.

Stolida. Ovate, ferruginous; head and thorax yellow; wing-cases variegated. Fabr. Inhabits South America.

Nigricornis. Ovate, brassy-black; head, sides of the thorax, and double spot at the base of the wing-cases ferruginous. Fabr.

Inhabits New Holland. Donov. Inf. N. H. Banksian cabinet.

Collaris. Ovate, violet; margin of the thorax white with a black dot. Linn.

Inhabits Europe and America, on willows. The thorax has two impressed dots.

Salicis. Ovate, blue; thorax smooth; margin thick and ferruginous. Fabr. Found in Saxony on the willow.

Senegalensis. Ovate, dull brassy; the thorax and wing-cases margined with ferruginous, thorax with a black dot. Fabr. Inhabits Senegal. Olivier.

Vininalis. Ovate, black; thorax rufous and bimaculated; wing-cases rufous. Linn. Geoffr. Found on willows in Europe.

Cyanipes. Ovate, rufous; wing-cases with blue dots up the apex. Fabr. Donov. Inf. New Holland. From the Banksian cabinet.

Cyanicornis. Ovate, rufous; thorax with a dorsal spot, and two spots of blue; wing-cases with eight blue spots, Fabr. Donov. Inf. New Holland. Banksian cabinet.

10-Punctata. Ovate; thorax red, behind black; wing-cases rufous, with about ten black dots. Linn.

Inhabits Europe. Varieties sometimes occur with a greater number of black dots, others which are destitute of them.

6-Punctata. Black; thorax rufous, with two black dots; wing-cases rufous with three black dots on each. Fabr. A native of Europe.

Pallida. Ovate, yellowish, with black eyes. Linn. and Geoffr.

An European species. A variety of this insect is sometimes found with indistinct black spots on the wing-cases and the body black.

Striata. Ovate, black, polished; wing-cases striated, testaceous, with deep black suture. Fabr. Inhabits the Cape. Banksian cabinet.

Notata. Ovate, thorax fulvous, with four black dots; wing-cases pale varied with black. Fabr. A native of the Cape, in the Banksian cabinet.

Rumicis. Ovate, thorax fulvous with four black dots; wing-cases fulvous with the suture and stripe in the middle black. Fabr. A native of Spain. Vahl.

Vulpina. Ovate, black; margin of the wing-cases four dots, and apex white; the last with three black spots. Fabr. Inhabits the Cape.

Crassicornis. Ovate yellowish wing-cases with two black dots. Fabr. Donov. Inf. New Holland.

Lapponica. Ovate; thorax green; wing-cases red with a blue band between a dot and lunate spot. Linn. Inhabits Europe.

Undulata. Ovate, rufous, wing-cases with three blue-waved lines. Linn. A native of India.

18-Guttata.

18-GUTTATA. Ovate, wing-cases fuscous with eight pale dots, some of which are connected. Fabr.

Described from the Banksian cabinet. Donov. Inf. New Holland.

POLYGONI. Ovate, blue; thorax, thighs, and vent, rufous. Linn. Common in most parts of Europe. Donov. Brit. Inf. &c.

RUSSICA. Ovate, blue; base of the antennæ, thorax, vent, and legs, rufous. Fabr. Inhabits Russia. Bœber.

BRUNNEA. Ovate, testaceous; wing-cases at the suture and small line in the middle fuscous. Fabr. Donov. Inf. New Zealand, &c. Banksian cabinet.

CEREALIS. Ovate, golden; thorax with three, wing-cases with five blue lines. A native of Europe. A most beautiful insect, being varied with stripes of blue, green, and crimson, and marked with slender lines of gold. Discovered British on one of the Cambrian mountains by Mr. Hudson, and inserted on this authority in Donov. Brit. Inf. and since in Marsh. Ent. Brit. Found on the butcher's-broom.

FASTUOSA. Ovate, golden, with three blue lines on the wing-cases. Linn. A native of Europe; sometimes found in England. Donov. Brit. Inf.

MODESTA. Ovate, brassy green; four lines on the thorax and two on the wing-cases coppery. Fabr. Inhabits the East Indies.

MARSHAMI. Thorax greenish golden; wing-cases golden, glossed with red and irregularly punctured. Donov. Brit. Inf. A new species.

AMERICANA. Ovate, brassy-green; wing-cases with five sanguineous streaks. Linn. Found in France. The head is brassy with a vertical scarlet spot.

FESTIVA. Ovate, brassy black, with three lines on the wing-cases, and the anterior part of the suture yellow. Fabr. Described from an American insect in the British Museum. It is the Chrysomela lineata of Degeer.

SPLENDIDA. Ovate, brassy-green; antennæ and ends of the feet black. Fabr. A native of Tranquebar. Lund.

GLORIOSA. Ovate, green, polished; wing-cases with a blue line. Fabr. *Chrysomela cacaliæ*, Schrank. Inhabits Italy.

SPECIOSA. Ovate, green, silky; wing-cases with two golden lines. Linn. Inhabits woods in Europe.

CYANEA. Ovate; thorax rotundate, and cylindrical; body blue and polished; legs black. Fabr. Inhabits South America.

PRÆTIOSA. Ovate; thorax globose; wing-cases very smooth; body blue. Fabr. Inhabits Germany. Smidt.

NITIDA. Ovate; thorax rotundate, brassy-green; antennæ blue. Fabr. Inhabits Siam.

AURATA. Ovate; thorax rounded and blue; wing-cases golden, with a blue margin. Fabr. Inhabits Pennsylvania.

LIMBATA. Ovate, black; wing-cases surrounded with a sanguineous border. Geoff. Inhabits Europe.

CARNIFEX. Ovate, black; wing-cases very smooth; exterior margin sanguineous. Fabr. A native of Germany.

SANGUINOLENTA. Ovate, black; wing cases dotted; exterior margin yellowish. Linn. Found on plants in Europe; a rare English species. Donov. Brit. Inf.

MARGINATA. Ovate, brassy-black; wing-cases punctured with yellow margin. Linn. A native of Europe. The wings are sanguineous.

SCHACH. Ovate; thorax brassy-black, and finely polished; wing-cases dusky, smooth, with margin sanguineous. Fabr. A native of Germany.

HANNOVERANA. Ovate, blue; margin of the thorax and wing-cases with a stripe on the latter ferruginous. Fabr. The antennæ of this insect are black; and the wing-cases striated with dots. One variety of this species has the stripe on the wing-cases abbreviated. Fabricius considers the Chrysomela Hannoverana, Ranunculi, and Potentilla, as the same insect.

AREATA. Ovate, black; thorax and wing-cases very smooth, with margin rufous. Fabr. Inhabits Paris. Cabinet of Bosc.

SCUTELLATA. Ovate, rufous; wing-cases with 5 black spots. Fabr. *Chrysomela scutellata*, Herbst. A native of Germany.

5-PUNCTATA. Ovate, black, with rufous thorax; wing-cases testaceous, with five black dots. Fabr. Inhabits Hamburgh. Dr. Schutz.

CROTONIS. Ovate, brassy-black, with yellow antennæ. Fabr. From the cabinet of Dr. Pflug. Inhabits South America.

PECTORALIS. Ovate, rufous; breast and abdomen at the base black. Fabr. *Dermestes rufus*, Herbst. Inhabits Germany.

LITURA. Ovate, pale rufous; wing cases at the suture, and a longitudinal line of black. Fabr. Marsh, &c. Inhabits England.

FLAVICANS. Ovate, yellowish; wing-cases cinereous-green. Fabr. Inhabits Germany. Hybner, &c.

SACRA. Ovate, above rufous; thoracic line, two dots, and suture of the wing-cases black. Linn. Inhabits Palestine.

HÆMORRHOIDALIS. Ovate, black, and polished; antennæ at the base, yellowish; above red. Linn. Found on the birch and alder in Europe.

FUCATA. Ovate, black, thorax, and wing-cases brassy-green. Fabr. Inhabits Italy.

AENEA. Ovate, brassy-green; tail ferruginous; antennæ and shanks black. Linn. Geoffr., &c. On plants in Europe.

2-PUNCTATA. Ovate, testaceous; wing-cases with a fuscous spot. Fabr. A native of the Cape. Banksian cabinet.

PHILADELPHICA. Ovate, green; wing-cases yellow with green spots; antennæ and legs ferruginous. Linn. A native of Pennsylvania.

ARMORACIÆ. Ovate, bluish, polished, beneath black. Linn. A native of Europe.

COCHLEARIÆ. Ovate, bluish, beneath black; wing-cases striated. Fabr. Inhabits plants in Germany.

PALLIPES. Ovate, black; wing-cases and legs very pale. Fabr. An inhabitant of Germany.

SOPHIÆ. Ovate, blue; shanks and ends of the feet yellow. Fabr. Found in Saxony.

ÆRUGINEA. Subrotund, brassy; legs ferruginous. Fabr. *Chrysomela metallica*, Ross. Fn. Etr. A native of Italy.

TENEBRICOSA. Apterous, blackish-purple; wing-cases uniformly punctured. Marsh. Fabr. *Chysomela tenebrioides*, Gmel. *Tenebrio lævigatus*, Linn.

AHENEA. Brassy-black, polished; legs pitchy. Marsh. A new British species.

OLIVACEA. Olivaceous-testaceous; eyes and suture of the wing-cases black. Forsk. Cent. 22. Inhabits England.

ATERRIMA. Black, polished; thorax very glabrous; wing-cases striated; legs somewhat ferruginous. Marsh. An English insect in the cabinet of Mr. Allen, as is also the following species.

CHALCEA. Brassy; wing-cases with obsolete striæ of dots. Marsh. Ent. Brit.

UNICOLOR. Black-blue, somewhat glossy, with numerous impressed dots. Marsh.

VIRIDI-

Viridi-ænea. Braſſy-green, with numerous dots; antennæ and legs ſame colour. Marſh.

Atro-violescens. Ovate, black-violet; wing-caſes ſtriated; legs pitchy. Marſh. Once taken near Holme, in Norfolk, by the Rev. Mr. Kirby.

** *Saltatoriæ;* having the poſterior thighs thick, and formed for leaping.

Flava. Yellow; thorax dotted with black; wing caſes violet. Fabr. *Altica thoracica*, Fabr. Syſt. Ent.

Caroliniana. Yellowiſh; thorax with two dots, wing-caſes with five ſtripes of yellow. Fabr. Gmel. *Crioceris caroliniana*, Fabr.

Oleracea. Greeniſh-blue. Linn. Fn. Suec. An European inſect.

Albicollis. Thorax pale; wing-caſes braſſy, with two ſpots and a band of gold. Fabr. A native of New Holland.

Fulvicollis. Thorax reddiſh; wing-caſes pale; ſuture and two ſpots black. Fabr. Country unknown.

Bicolor. Rufous; wing-caſes, and poſterior thighs blue. Degeer, &c. Inhabits America.

Quadrifasciata. Ferruginous, with four white bands on the wing-caſes. Fabr. This is a large inſect and inhabits Cayenne.

Cincta. Black; wing caſes braſſy-green; margin and two dots white. Fabr. Inhabits Luſitania.

Quadriguttata. Ferruginous; thorax white; wing-caſes black, with four white dots. Fabr. Inhabits Cayenne.

Biguttata. Ferruginous, thorax and wing-caſes with two white dots. Fabr. A native of Cayenne.

Glabrata. Thorax pale, with three black dots; wing-caſes black, with two white ſtripes. Fabr. *Crioceris glabrata*, Fabr. Sp. Inſ.

Nobilitata. Ferruginous, margin of the wing-caſes and band white. Fabr. A native of Cayenne.

Chrysocephala. Blue-black; head and four anterior legs pale yellow. Linn. Fn. Suec. Inhabits Sweden.

Hyoscyami. Greeniſh-blue; legs teſtaceous, poſterior thighs violet. Linn. Fn. Suec. *Capricornus exiguus ſaltatorius*, Ray. Inhabits Europe.

Quadripustulata. Black; wing-caſes with four rufous dots. Fabr. Inhabits Europe.

Anglicana. Black; wing-caſes and ſhanks pale. Fabr. Found on plants in England.

Atricillæ. Black, thorax, wing-caſes, and ſhanks teſtaceous. Linn. Fn. Suec.

Modeeri. Braſſy, poliſhed; wing-caſes yellow at the tip; anterior legs and ſhanks of the poſterior ones pale yellow. Linn. Inhabits Sweden and other parts of Europe.

Nitidula. Green, ſhining; head and thorax golden; legs ferruginous. Fabr. Inhabits Europe, on the willow.

Trifasciata. Above whitiſh with three brown bands. Fabr. Found on plants in Europe.

Nigripes. Braſſy-green; legs black. Fabr. Inhabits England.

Tabida. Pale, with the eyes black. Fabr. Found on plants in Europe.

Brassicæ. Black; wing-caſes pale, teſtaceous; margin entirely, and a band in the middle black. Fabr. A ſmall ſpecies found in Germany.

Nemorum. Wing-caſes yellow, with the margin entirely black. Fabr. Found on various plants in Europe.

Atra. Black, poliſhed; antennæ at the baſe, and tip of the feet pitchy. Geoffroy, &c. Found in France and Germany.

Rustica. Black; antennæ, legs, and tip of the wing-caſes teſtaceous. Gmel. An European ſpecies. The wing-caſes are very finely punctured.

Pulicaria. Black; wing-caſes with a poſterior ferruginous ſpot. Gmel. Very ſmall. Inhabits Europe.

Rufipes. Obovate, blue; head, thorax, legs, and antennæ rufous. Linn. Inhabits Sweden.

Testacea. Teſtaceous, gibbous; wing-caſes very ſmooth. Fabr. Geoffr. Inhabits Europe.

Fascicornis. Obovate, blue; head, thorax, and legs rufous; antennæ, fuſcous. Hornſt. Inhabits Germany.

Holsatica. Black, poliſhed; a red dot at the end of the wing-caſes. Fabr. A native of Europe.

Æquinoctialis. Thorax red; wing-caſes violet, with four alternate white ſpots. Degeer, &c. Found in South America.

Lens. Entirely blue-back, with dotted wing-caſes. Thunberg. Inhabits Upſal.

Exclamationis. Thorax black; wing-caſes black, with four yellow ſpots. Thunberg. Inhabits Upſal.

Hudsonias. Black, ſomewhat oblong; baſe of the antennæ ferruginous. Forſt. Nov. Inſ. A native of South America.

Quadrinotata. Black, antennæ yellowiſh at the baſe, wing-caſes with four teſtaceous ſpots. Pontoppid. Inhabits Denmark.

Pusilla. Black, antennæ and legs pale. Müll. Inhabits Denmark.

Luteola. Pale yellow, eyes, breaſt, and tip of the antennæ black. Müll. Inhabits Denmark.

Flaveola. Black; thorax and head rufous; wing-caſes, antennæ, and legs pale yellow. Müll. Inhabits Denmark.

Latiuscula. Fuſcous-black; ſhanks and joints of the feet ſomewhat yellowiſh. Müll. Inhabits Denmark.

Cruciferarum. Oblong, braſſy-black; legs black. Geoff. Inhabits France.

Denigrata. Black; thorax and wing-caſes yellow, mouth black. Geoffr. Inhabits France.

Truncata. Black; wing-caſes truncated, the tip ferruginous, legs and antennæ rufous. Scopoli. Inhabits Carniola.

Ovalis. Braſſy-black, legs black. Geoffr. Inhabits France.

Striata. Blue; head, thorax, antennæ, and legs rufous; wing-caſes ſtriated. Degeer. A native of Europe.

Lævigata. Blue; wing-caſes ſprinkled with dots; ſhanks ferruginous. Geoffr.

Crenata. Black; wing-caſes braſſy with crenated ſtriæ, antennæ at the baſe and the ſhanks pitchy. Muſ. Leſk. Linn. Inhabits Europe.

Discolor. Head, and thorax black; wing-caſes teſtaceo-fuſcous, glabrous; four anterior legs, and the ſhanks of the hinder pair ſomewhat teſtaceous. Linn. Muſ. Leſk. Inhabits Europe.

Picipes. Braſſy-green, dotted, legs pitchy, wing-caſes bay-colour, black towards the future. Linn. Muſ. Leſk. Inhabits Europe.

Annulata. Braſſy fuſcous; wing-caſes with crenated ſtriæ; antennæ at the baſe and four anterior ſhanks rufous, the latter with a braſſy-brown ring. Linn. Leſk. Muſ. Inhabits Europe.

A further number of the Linnæan Chryſomelæ will be found under the new genera Cnodulum, Crioceris, Cryptocephalus, Erotylus, and Galleruca.

CHRYSOMITHRES, in *Ornithology*, the name by which ſome call the gold-finch. See Fringilla *carduelis*.

C H R

CHRYSOPAGION, in *Natural Hiſtory*, a name by which ſome of the middle age writers have called the gem deſcribed by Pliny under the name of the *chryſolampis*. Salmaſius is of opinion that it was only a foul kind of the *chryſopraſius*, of which Pliny ſays, that ſome of them were full of ſpecks, and of a variable colour.

CHRYSOPETRON, a name given by Pliny, and others, to the yellower kind of the ancient topaz, that is, our chryſolite.

CHRYSOPHRYS, in *Ichthyology*, among the Greek and Latin authors, a name ſynonymous with Aurata, and applied by them to the fiſh called by Linnæus *Sparus auratas*, which ſee.

CHRYSOPHYLLUM, in *Botany*, (from χρυσος, *gold*, and φυλλον, *a leaf*. Golden leaf.) Linn. gen. 265. Schreb. 355. Willd. 400. Juſſ. 152. Vent. 2. 436. Caimitier. Enc. Meth. Claſs and order, *pentandria monogynia*. Nat. Ord. *Dumoſæ*, Linn. *Sapotæ*, Juſſ.

Gen. Ch. *Cal.* Perianth ſmall, permanent; deeply divided into five, roundiſh, obtuſe ſegments. *Cor.* monopetalous, ſhort, bell-ſhaped, five-cleft; ſegments roundiſh, much expanded; accompanied by five ſmall ſcales, which give it the appearance of being ten-cleft. *Stam.* Filaments five, ſhort, attached to the top of the tube; anthers roundiſh, didymous, incumbent. *Piſt.* Germ ſuperior, roundiſh; ſtyle ſhort; ſtigma obtuſe, obſcurely five-cleft. *Peric.* Berry one or ten-celled, large. *Seeds* one in each cell, bony, compreſſed, marked with a ſcar, ſhining.

Eſſ. Ch. Cor. bell-ſhaped, apparently ten-cleft; alternate ſegments ſpreading. Berry one ſeed in each cell.

Sp. C. *cainito*, Linn. Sp. Pl. 1. Mart. 1. Lam. 1. Willd. 1. Jacq. Amer. 51. tab. 37. pict. 30. tab. 51. Lam. Ill. Pl. 120. Broad-leaved ſtar-apple. "Leaves egg-ſhaped, downy and ſhining underneath; fruit roundiſh, ſhaped like an apple." β. Jamaicenſe; with purple fruit, Jacq. Amer. 52. pict. 31. Brown Jam. tab. 14. fig. 2. γ. cæruleum with fruit entirely blue. A tree from thirty to forty feet high, with a large ſpreading head. *Leaves* about five inches long, and two and a half broad, regularly ſtriated with fine lateral parallel nerves, alternate, petioled, egg-ſhaped, rather acute, quite entire, ſmooth, deep green above, covered underneath with a very fine ſilky ſhining down of a ferruginous gold colour. *Flowers* ſmall, axillary and faſcicled upon each peduncle. *Fruit* globular, about the ſize of a common apple, fleſhy, ſoft, with a ſmooth ſkin, and of a roſe colour, with a yellowiſh tint intermingled with a ſhade of green. It contains a milky, glutinous, ſweetiſh pulp, which envelopes from five to ten nuts, brown without, a little flattened, of an even ſurface, with a rude rugged border. The varieties β and γ appear to differ only in the colour of the fruit. Though the germ always contains the rudiment of a nut in each of the ten cells, it moſt frequently happens that ſome of them afterwards prove abortive. A native of the Weſt Indies, where the fruit is eaten, and the wood uſed for building. 2. C. *olivæforme*, Lam. Encyc. 2. Ill. 2471. (C. cainito; β. Linn. Sp. C. monopyrenum; Willd. Cainito foliis ſubtus aureo, fructu olivæforme; Plum. gen. 10. Burm. Amer. tab. 69. Acomas; Nichol. Doming. 141?) "Leaves ovate-oblong, tomentous and ſhining underneath; fruit the ſhape of an olive, with one ſeed." Damſon plum; Brown Jam.? A tree about the ſize of a common apple-tree, with a rough ruſſet bark beſprinkled with ſmall white ſpots. *Branches* ſpreading; ſmaller ones a little zigzag. *Leaves* alternate, ſomewhat reſembling thoſe of the citron; ſmooth, ſhining and dark green above; covered with a ſilky, golden down underneath; traverſed by a longitudinal rib, whence proceed laterally ſeveral parallel nerves a little curved. *Flowers* ſmall, axillary, faſcicled, one on each peduncle; calyx covered with a golden ferruginous down; ſtigma with five ruſſet diviſions. *Fruit* ſoft, the ſhape of an olive, but a little larger, of a dark violet colour when ripe, having a pleaſant vinous flavour, and containing a bluiſh nut, which encloſes a tender, oblong, acute kernel. Plum. MSS. A native of the Weſt Indies, flowering in October and November, and ripening its fruit in May and June. 3. C. *acuminatum*, Lam. Illuſ. 2469. "Leaves egg-ſhaped, acuminate, ſtriated with parallel lines, downy and ſhining, but pale underneath. A native of St. Domingo. La Marck queſtions whether this be not C. monopyrenum of Swartz. If ſo, there are two ſpecies with only one nut, and monopyrenum cannot be properly retained as a ſpecific name. 4. C. *anguſtifolium*, Lam. Ill. 2470. "Leaves lanceolate, ſtriated with parallel lines, ſhining, covered with a ferruginous down underneath; berries the ſhape of an olive." *Leaves* reſembling thoſe of the olive or privet. *Berry* ſometimes with two ſeeds. La Marck doubts whether this be ſpecifically different from his olivæforme. Are not all three merely varieties of the ſame ſpecies? And is there not ſome ground for a conjecture, that, when more accurately examined, they will be found to have a germ with ten cells, though it ripens only one, or at moſt two ſeeds? In this caſe the generic character may remain as it was firſt formed by Linnæus. 5. C. *microcarpum*, Willd. 3. Mart. 5. Swartz. Prod. 49. Ind. occ. 1. 482. "Leaves egg-ſhaped, ſmooth, pubeſcent underneath; berries oblong, oblique, one-ſeeded." *Fruit* very ſweet. Is not this alſo a variety of C. olivæforme? 6. C. *argenteum*, Mart. 2. Lam. Illuſ. 2472? Jac. Amer. 53. tab. 38. fig. 1. "Leaves falcate-ovate, tomentous and ſhining underneath." Swartz. "Leaves egg-ſhaped, acuminate-falcated; younger ones with a ſhining ſilvery down underneath; the older ones ſmooth on both ſides." Lam. A native of the Weſt Indies. 7. C. *pauciflorum*, Lam. Ill. 2473. Jacq. Amer. tab. 38. fig. 2.? "Leaves egg-ſhaped, acuminate, nearly ſmooth on both ſides, with only a few flowers in the axil of each leaf. A native of Martinico. 8. C. *rugoſum*, Mart. 6. Willd. 5. Swartz. Prod. 49. Ind. occid. 1. 484. "Leaves oblong, acuminate, ſmooth on both ſides; fruit acuminate, rough. A native of woods on mountains in Jamaica. 9. C. *pyriforme*, Willd. 6. (C. Macouco; Lam. Encyc. 4. Illuſt. 2475. Aub. guin. 1. tab. 92.) "Leaves oblong, acuminate, ſmooth on both ſides; fruit pear-ſhaped, with an even ſurface. A tree thirty feet high, and two in diameter, with a large much branched head; bark ſmooth, greyiſh, yielding when rounded a milky juice; wood white; hard and brittle. *Leaves* alternate, oval-oblong, pale green on both ſides. *Fruit* orange-coloured, on ſhort peduncles, growing from two to four together; fleſhy, milky, encloſing ſeveral roundiſh nuts, which contain a white, ſweet, eſculent kernel. According to Aublet the fruit has a more pleaſant flavour than that of the firſt ſpecies. 10. C. *glabrum*, Linn. Sp. Pl. 2. Mart. 3. Lam. Encyc. 3. Willd. 7. Jacq. Amer. tab. 38. fig. 2. "Leaves ovate-oblong, acute, ſmooth on both ſides; fruit elliptical, with an even ſurface." A tree fifteen feet high, ſtraight, branched. *Leaves* alternate, petioled, quite entire, a little coriaceous. *Fruit* blue, about the ſhape and ſize of a ſmall olive, with a ſweetiſh vinous flavour. A native of woods in Martinico.

CHRYSOPHYLLUM *carolinenſe*; Jacq. See BUMELIA *tenax*.

CHRYSOPHYLLUM *crinito*; Aubl. See BUMELIA *tenax*.

CHRYSOPHYLLUM *manglillo*; Lam. Illuſt. See BUMELIA *manglillo*.

CHRYSOPHYLLUM *macrophyllum*; Lam. Ill. See BUMELIA *nervoſa*.

Chrysophyllum *barbasco*; Læfl. it. See Jacquinia *armillaris*.

CHRYSOPILON, in *Natural Hiſtory*, a name given by ſome ancients to a ſpecies of the beryl, which had a yellowiſh tinge.

CHRYSOPIS, more correctly *Chryſops*, in *Entomology*, a name applied by ſome old writers to the inſect called in England the "Golden Eye," from the beautiful gold colour of its eyes. It is of a moderate ſize, with four extremely thin and tranſparent wings of a ſomewhat ſilvery colour, with green ribs or nerves; it is common in gardens, eſpecially about elder trees, and has a remarkably ſtrong ſmell. In the days of Mouffet this inſect was known by the name of *muſca chryſops*; Ray calls it *muſca quadripennis corpore luteo-viridi*, and Petiver, *perla merdam olens*. With Linnæus, and other modern naturaliſts, it is a ſpecies of *hemerobius*. See Hemorobius *perla*.

CHRYSOSPLENIUM, in *Botany*, (from χρυσος, and σπλην, *the ſpleen*, on account of the golden colour of the flowers, and of the ſuppoſed virtue of the plant in diſeaſes of the ſpleen.) Linn. 558. Schreb. 763. Willd. 886. Gært. 252. Tourn. 60. Juſſ. 309. Vent. ii. 284. Dorine, Lam. Encyc. Golden ſaxifrage. Claſs and order, *decandria digynia*. Nat. ord. *Succulentæ*, Linn. *Saxifragæ*, Juſſ.

Gen. Char. *Cal.* perianth one-leafed, ſhort, permanent, coloured, four, or very rarely five-cleft; ſegments oval, obtuſe, ſpreading, oppoſite ones narrower. *Cor.* none. *Stam.* filaments eight, very rarely ten, erect, very ſhort, attached to the lower part of the calyx; anthers ſimple, round. *Piſt.* germ half inferior, ending in two awl-ſhaped ſtyles, the length of the ſtamens; ſtigmas obtuſe. *Peric.* capſule two-beaked, one-celled, half bivalve, ſurrounded at its baſe by the calyx. *Seeds* numerous, ſmall.

Eſſ. Ch. Calyx four or five-cleft, coloured. Corolla none. Capſule two-beaked, one-celled, half inferior, half bivalved, many-ſeeded.

Obſ. Linnæus placed this genus in the claſs *decandria*, on account of the terminating flower, which, in his ideas, determines the true character of the fructification, being ſometimes decandrous; but as this is of very rare occurrence, and as none of our Engliſh botaniſts, after repeated reſearches, have found it ſo in a ſingle inſtance, it has ſcarcely a right to be conſidered as a decandrous plant, notwithſtanding its natural affinity to ſaxifraga. In an artificial ſyſtem octandria ſeems to be its proper claſs, where Dr. Stokes in Withering has accordingly placed it.

Sp. 1. C. *alternifolium*, Linn. Sp. Pl. Mart. Willd. Lam. Encyc. Gært. tab. 44. Flor. Dan. tab. 366. Eng. Bot. 54, but unfortunately taken from an imperfect ſpecimen without root-leaves. (Saxifraga aurea dodonæi, Bauh. Hiſt. S. aurea, foliis pediculis oblongis, Rai Syn. 158. Sedum rotundifolium paluſtra, foliis pediculis longis inſidentibus, Moriſ. Sect. 12. tab. 8. fig. 8.) Alternate-leaved golden ſaxifrage. "Leaves alternate." *Root* perennial, fibrous, throwing out offſets, but no creeping ſuckers. Whole plant ſucculent, tender. *Stem* three-ſided. *Leaves* all deeply notched; root-leaves two or three, kidney-ſhaped, bluntly notched, on long hairy petioles; ſtem-leaves alternate, one of them ſolitary, about the middle of the ſtem, the reſt cluſtered, partly about the root, and partly near the flowers. *Flowers* gold-coloured; in a terminal, dichotomous leafy corymb. A native of England, and other northern parts of Europe, flowering in May; intermingled with the next ſpecies, but much more rare. 2. C. *oppoſitifolium*, Linn. Sp. Pl. Mart. Willd. Lam. Curt. Lond. Faſc. ii. tab. 27. Flor. Dan. tab. 365. Eng. Bot. tab. 490. (Saxifraga aurea, Rai. Syn. 158. Lob. Ic. 612. Sedum paluſtre rotundifolium, Moriſ. tab. 8. fig. 7.) Oppoſite-leaved golden ſaxifrage. "Leaves oppoſite." Habit of the preceding, but paler. *Root* perennial. *Stems* creeping at the bottom, ſquare, or with two oppoſite deep furrows, very tender, beſet with a few ſtiffiſh white hairs about four inches high. *Leaves* petioled, ſpreading, roundiſh, with a few ſtiffiſh white hairs on the upper ſurface, repand, ſomewhat fleſhy, yellowiſh green, whitiſh underneath; the upper ones more deeply notched. *Flowers* yellow, in a ſeſſile faſtigiate corymb. The notched glandular ring, which ſurrounds the baſe of the germ, is placed between that part and the inſertion of the ſtamens, and therefore, as Curtis remarks, cannot be, as Linnæus ſtyles it, a receptacle. It ſeems to be properly a nectary. A native of moiſt places in England and other parts of the north of Europe, flowering, with the preceding, in May.

CHRYSOPOLIS, in *Ancient Geography*, an epiſcopal town of Aſia, mentioned in the council of Conſtantinople.—Alſo, an epiſcopal ſee in Africa, in Mauritania.—Alſo, an ancient town of Aſia Minor, ſituated near Chalcedon, and oppoſite to Byzantium. It had a fine port; and when the Perſians were maſters of it, they collected there the tribute which they drew from the different towns. It was a place of commerce with the inhabitants of Chalcedon. Xenophon ſays, that the Athenians encompaſſed this place with walls; that they impoſed a tenth on the ſhips that came hither from the Euxine ſea; and that they ſtationed here a fleet of 30 ſail for the ſecurity of the port.—Alſo, an ancient epiſcopal town of Aſia, called *Chriſtopolis*, under the metropolitan ſee of Boſtra, in the patriarchate of Antioch.

CHRYSOPRASE. The colour of this mineral is apple-green, paſſing into graſs and olive-green and greeniſh grey. It is found in maſs, in angular fragments, and thick plates. Internally it exhibits a ſlight degree of luſtre. Its fracture is even, paſſing ſometimes into fine ſplintery and flat conchoidal, with indeterminate ſharp-edged fragments. Its hardneſs is ſomewhat leſs than that of chalcedony. Sp. gr. 3.25.

Before the blow-pipe chryſopraſe becomes opake and colourleſs, but it is infuſible *per ſe*. It has been analyſed with great accuracy by Klaproth, and appears to conſiſt of

Silex	-	96.16
Lime	-	0.83
Oxyd of nichol		1
		97.99

It has hitherto been found only at Koſemutz in Lower Sileſia, imbedded in ſerpentine, along with quartz, opal, chalcedony, &c. It paſſes into hornſtone and chalcedony, and appears to differ from this laſt in little elſe than colour.

When kept long in a warm and dry ſituation it loſes the greateſt part of its colour. The apple-green variety is in ſome eſtimation among jewellers, and is cut into ſtones for rings.

CHRYSOPRASUS, in *Chriſtian Antiquity*, the tenth of thoſe precious ſtones which adorned the foundation of the heavenly Jeruſalem; the colour of it was green, much like that of a leek, but ſomething inclining to that of gold, as its name imports.

CHRYSORHOAS, or Chrysorrhoas, in *Ancient Geography*, a river of Aſia, in Syria, which ran near the town of Damas, and fertilized the environs of this town. Pliny and Strabo repreſent this river as diſtributing itſelf in ſtreams

ſtreams.—Alſo, a river of Aſia, in the Colchide territory. Pliny.—Alſo, a river of Aſia Minor, in Lydia, the ſource of which is placed by Pliny near mount Tmoles.

CHRYSORRHOES, a river ſituated towards the extremity of the peninſula on the ſouth-eaſt of the Argolide. It watered the town of Trazena; and derived its name of the "River of Gold," from the quantity of this metal which it depoſited.

CHRYSOSTOM, John, in *Biography*, an eminent and very eloquent father of the church, was a native of Antioch about the year 347. The name of Chryſoſtom, ſignifying in the Greek *golden-mouth*, was not applied to him till after his death, when his works had rendered him illuſtrious for eloquence. He was, at a very early age, inſtructed in the principles of the Chriſtian religion, and derived all the advantage which the beſt maſters in human learning could yield him. He was originally intended for the bar, but, being diſguſted with the profeſſion, he applied himſelf to the ſtudy of the Scriptures, and other departments of ſacred literature: he perſuaded alſo two of his friends, Theodorus and Maximus, to purſue the ſame courſe. When he was about twenty-ſeven years of age, he retired from the world to an aſcetic life, firſt in company with a monk upon a mountain near Antioch, and then in a cave by himſelf. The auſterities which he voluntarily inflicted on himſelf, injuring his health, he returned to Antioch, after having paſſed ſix years in the condition of a hermit. He was then ordained a deacon, and afterwards a prieſt, and, devoting himſelf to the labours of the pulpit, he became ſo celebrated for his eloquence, that, upon the death of Nectarius, he was unanimouſly choſen as patriarch or archbiſhop of Conſtantinople, in 397. While Chryſoſtom was at Antioch he wrote ſeveral books, and acquired much reputation as a preacher. He was a man of great ſimplicity of character, ſeverity of manners, and freedom of ſpeech, which brought him many enemies: but, notwithſtanding his virtues, which are admitted on all hands, it is equally notorious, that he was haughty and arbitrary. It was with difficulty that he was forced from Antioch, but when he came to Conſtantinople, he avoided as much as poſſible promiſcuous ſociety; he devoted his time to his ſtudies and profeſſional duties; and all that he ſaved by economy in his own expences, he liberally beſtowed on the poor. He erected new hoſpitals in that metropolitan city, took care of the ſick and the ſtrangers, and provided for widows and virgins. He was an enthuſiaſtic admirer of the monaſtic life, and exhorted the young of both ſexes to a ſtate of celibacy; and, in other reſpects, he preached up a rigour of manners very incompatible with the character of the times. He indulged a perſecuting ſpirit againſt thoſe who did not rank themſelves with Chriſtians, pulling down the pagan temples, and haraſſing, as much as poſſible, thoſe who were deemed heretics. He extended his archiepiſcopal juriſdiction, and, in a viſitation of the Aſiatic provinces, he depoſed thirteen biſhops of Lydia and Phrygia. This temper, and theſe auſtere manners, created him many enemies, and he was at length accuſed of diſreſpect to the empreſs Eudoxia, and cruelty to ſome of the clergy; a ſynod was convened, in the year 403, before which, articles of accuſation were brought againſt Chryſoſtom. He was ſummoned, but, declining to put himſelf into the hands of his profeſſed enemies, he was condemned, depoſed, and baniſhed. When this event was known at Conſtantinople, a dreadful tumult was excited, which created ſo much alarm, that Eudoxia, who was his principal enemy, petitioned for the archbiſhop's return. Another ſynod, conſiſting of ſixty biſhops, aſſembled at Conſtantinople, and reſcinded all that had been done againſt Chryſoſtom, and he was reſtored with great triumph. Toward the end of this year, the empreſs cauſed her own ſtatue to be erected near the church, and the people celebrated public games before it to her honour. Chryſoſtom, confiding, perhaps, in his own popularity, and irritated againſt the empreſs, preached againſt this as an indecency, openly declaring, that the ſtatue had been erected in contempt of the church. The empreſs endeavoured again to aſſemble the ſynod, but the prelate, far from being intimidated, reproached her conduct in ſtill more bitter terms, repreſenting her as another Herodias, who wiſhed to have the head of another John, meaning his own, in a charger. The empreſs now was bent on his deſtruction, in which ſhe ſucceeded. Chryſoſtom was depoſed, and baniſhed. On the day of his departure, the great church and adjoining palace were burnt to the ground. He was firſt taken to Nice, and thence was conveyed to the place aſſigned for his reſidence, which was Cucuſus, a deſolate town among the ridges of mount Taurus, in Leſſer Armenia. The death of the empreſs, ſome peculiar circumſtances in that of Cyrinus, biſhop of Chalcedon, a bitter enemy of Chryſoſtom, and a dreadful hail-ſtorm, which happened ſoon after his baniſhment, were interpreted by his friends as marks of the Divine diſpleaſure at the conduct of his enemies. Chryſoſtom, in the mean time, did not ſuffer his mind to ſink under his misfortunes; he actively employed himſelf in maintaining a correſpondence with the moſt diſtant provinces, in conſoling and exhorting his adherents left behind him in the metropolis, and in ſupporting his cauſe before the ſee at Rome, which had always been diſpoſed to favour him. That he was able to live ſo comfortably was a great mortification to his enemies: they procured an order for his removal ſtill farther from the capital, to Pitycens, a town on the Euxine Sea; but he died on his journey, at Comanis in Armenia, owing to the great hardſhips to which he was expoſed. After his death, the Eaſt and Weſt were for ſome time divided with reſpect to the tribute due to his memory. By the latter, it was held in great reverence; but the eaſtern biſhops refuſed to inſert his name in the regiſters of thoſe who were to be mentioned with honour at the celebration of the euchariſt. Within ten years, he was generally revered as a ſaint, and, in the year 438, at the ſolicitation of the clergy and people of Conſtantinople, his relics were tranſported from their obſcure ſepulchre to the royal city. The emperor Theodoſius advanced to receive them as far as Chalcedon; and falling proſtrate on the coffin, implored, in the name of his guilty parents, the forgiveneſs of the injured ſaint. Chryſoſtom was undoubtedly the moſt diſtinguiſhed of all the Greek fathers, as Auſtin was among the Latins. He is ſaid to have compoſed more than a thouſand ſeparate pieces; but the greateſt part of his writings are ſermons, or expoſitions of ſcripture delivered as ſermons, with practical improvements annexed to them. His ſtyle is free, copious, and unaffected. He is dignified and correct in his phraſeology, varied and abundant in his figures and illuſtrations. His diſcourſes and illuſtrations of ſcripture are often more fanciful than ſolid, but copious, and full of particulars. In his declamations againſt the vices and follies of the times, he has alluded to ſo many circumſtances, that a hiſtory of the manners and cuſtoms of the times may be derived from his works, which is no where elſe to be met with. The moſt regular of his treatiſes, is a dialogue on the duties of a biſhop. The moſt complete edition of his works is that publiſhed by Montfaucon, the learned Benedictine, in 1734, which is accompanied with a life of the author, prefaces, notes, and various readings. Gibbon. Lardner.

CHRYSTAL. See Crystal.

Chrystal *Mineral*, the ſame as *Sal prunella*.

CHRYSTALLINE. See CRYSTALLINE.

CHRYSTALLIZATION. See CRYSTALLIZATION.

CHRYSTALLUS, in *Ancient Geography*, a name anciently given, according to Plutarch, to the river Thermodou of Scythia, becaufe it was frozen even in fummer.

CHRYSUM, a name given by Ptolemy to the third mouth of the river Indus, reckoning from the weft.

CHRYSUS, a river of Afia Minor, which ran towards Laodicea.—Alfo, a river of Spain, placed by Feftus Avienus in Bœtica.

CHTHONIA, in *Antiquity*, a feftival kept in honour of Ceres, called *Chthonia*. For the ceremonies obferved in it, fee Pott. Archæol. lib. ii. cap. 20.

CHVALINSK, or KHVALYNSK, in *Geography*, a town of Afiatic Ruffia, in the government of Saratof, and alfo its adjacent diftrict, fituated on the Volga, 350 miles S.E. of Peterfburg. N. lat. 52° 25'. E. long. 57° 54'.

CHUB, in *Ichthyology*. See CYPRINUS *Cephalus*.

CHUBANA, in *Ancient Geography*, a town of Afia in Mefopotamia, feated on the eaftern bank of the Euphrates.

CHUBB, THOMAS, in *Biography*, a controverfial writer, was born Sept. 21, 1679, at a fmall village near Salifbury. He received no other education than the firft elements of reading and writing, and was obliged at an early age to feek a livelihood by the labour of his own hands. He was apprentice to a glover, with whom, and afterwards with a tallow-chandler, he worked as a journeyman. Being poffeffed of uncommon natural abilities, and having a very ftudious turn of mind, he fpent his leifure hours in the acquifition of knowledge of various kinds, but his inclination led him chiefly to the ftudy of divinity. In 1710, Mr. Whifton publifhed the hiftorical preface to his "Primitive Chriftianity Revived." The principal point difcuffed in this preface was the fupremacy of God the Father: Chubb read the piece, but not being fatisfied with the ftatement of the argument, he drew up his own opinion on the fubject, which, at the defire of one of his own friends, was fhewn to Mr. Whifton. It fo well coincided with the opinions of this very learned divine, that by the leave of Chubb, he publifhed it with a few alterations which did not in the leaft affect the grand point in queftion. In the year 1715 it appeared under the title of "The Supremacy of the Father afferted; or Eight Arguments from Scripture to prove that the Son is a Being inferior and fubordinate to the Father, and that the Father is the Supreme God." The perfpicuity and ability with which this tract was written procured Mr. Chubb great reputation, but he was alfo affailed from various quarters with much vehement abufe. He found himfelf called upon to vindicate himfelf and his work, and thus commenced the controverfy that ended only with his life. In the year 1730 he publifhed a collection of tracts, in a quarto volume, upon various important topics, moral and theological. Of the author, Mr. Pope fpeaks with great refpect, and fays, that "he had read the whole volume with admiration of the writer, though not always with approbation of the doctrine." The next piece publifhed by Chubb was "A Difcourfe concerning Reafon in Matters of Religion, with Reflections upon the comparative excellency and ufefulnefs of Moral and Pofitive Duties." This meeting with oppofition, he publifhed a vindication of it, infifting more ftrongly upon the fufficiency of reafon to all human beings. In 1734 he publifhed a volume confifting of tracts on the infpiration of the New Teftament; and on the refurrection of Chrift as a proof of the divinity of the doctrine which he taught; on the cafe of Abraham being ordered to offer up his fon; and on the parable of the unmerciful fervant. In the year 1738 he publifhed "The true Gofpel of Jefus Chrift afferted," in which he profeffes to feparate the corruptions of Chriftianity from its effence. One of his next pieces was an "Enquiry into the Ground and Foundation of Religion;" in this he vindicates the principles of natural religion. He afterwards proceeded to the examination of miracles, and at length appears to have taken a decided part with thofe, whom it has been the fafhion to denominate free-thinkers, but who, in truth, reject the truths of revealed religion. In his pofthumous works, publifhed in 1748, we have his mature thoughts on a variety of topics relative to religion and morality, in which though he feems willing to give up the evidences of the Jewifh and Chriftian religion, yet he draws the conclufion that Jefus was probably fent by God as an inftructor of mankind. Chubb began, as we have feen, to write as a rational Chriftian, and he never exprefsly denied the divine miffion of Jefus; he engaged, however, in controverfies to which his limited knowledge was not equal, though his natural abilities might be well adapted for fuch important difquifitions; there is no reafon to believe that he ever examined the hiftorical evidences of revealed religion, yet in his pofthumous works he infinuates many things calculated to prejudice the young and the thoughtlefs againft it. He denies a particular providence, and the neceffity of prayer. With refpect to a future ftate, he expreffes himfelf very varioufly, and without much confidence on either fide of the queftion. Mr. Chubb was never anxious to rife above the humble condition in which fortune had placed him: to the laft period of life he took pleafure in affifting in the trade of a tallow-chandler. He met with many friends who affifted him, among thefe was fir Jofeph Jekyl, who made him his companion in his intervals of leifure. In this fituation Chubb had an opportunity of becoming acquainted with many of fir Jofeph's friends, though it has been afferted that on extraordinary occafions he affifted as a fervant out of livery. It is certain his ftay with that gentleman was not long; he chofe to return to Salifbury. The generofity of his friends followed him in his retreat. Mr. Chefelden, the celebrated furgeon, was one of his benefactors; and in the latter part of his life, Mr. Samuel Dicker offered to fettle an annuity of 50 pounds upon him if he would leave Salifbury, but this offer he declined, as he did not at that time fpend the income of his fortune. He injured his health by too intenfe ftudy; however his life was prolonged to his fixty-eighth year, and agreeably to a wifh which he had been accuftomed to exprefs, he was happily exempted from many of thofe evils which too frequently aggravate the bitternefs of death. On the eighth of Feb. 1746-7, after a fhort complaint of an unufual pain in his ftomach, he fuddenly breathed his laft as he fat in his chair. He was buried in St. Edmund's church in Salifbury. The eminence of Mr. Chubb's intellectual abilities is generally allowed, and on this account he was not only admired by the perfons already named, but by Dr. Clarke, bifhop Hoadly, Dr. John Hoadly, and many other diftinguifhed divines. With refpect to his moral character, he was uniformly formed for integrity, fimplicity and fobriety of manners, and he attended the fervices of his parifh church to the time of his death. Biog. Brit. Leland.

CHUBDARS, a name given in Bengal to thofe Moorifh fervants who are employed to carry meffages, &c. for ftate. Thofe in the Dutch fervice carry a long ftaff in their hand, which is entirely covered with filver, with which they go before the palankeen of the directors and of the two members of the council next in rank; but the latter are allowed no more than two chubdars, and their ftaves may be only half plated with filver.

CHUCHIA, in *Zoology*, a name given by Cardan, Oviedo,

Oviedo, and fome others, to the opoffum, *Diadelphis opoffum* of Schrebers?

CHUCHUNGUA, in *Geography*, a fmall place of South America, in the country of Jaen de Bracamoros, feated on a river of that name, in 25° 29′ S. lat. As the river Marauon is not navigable up to Jaen, this town ferves as a port to it, and thofe who wifh to embark on the Maranon go by land from Juen to Chuchungua, and from hence fall down into the Maranon. This town lies four days journey from the city, but in this mode of reckoning it fhould be confidered, that fuch are the difficulties of the road, as to render it impoffible to travel in half a day or fometimes a whole day, an interval which might be paffed over on good ground in an hour or two.

CHUCKING, among *Rope-makers*, denotes a long, ftout, coarfe, hemp, rather foul, and ufed for making inferior rope. Short chucking is the foul hemp from the ends of the long chucking.

CHUCUITO, *jurifdiction of*, in *Geography*, a province or jurifdiction of South America belonging to the diocefe of La Paz and audience of Charcas. It begins about 20 leagues W. of Paz; and as fome part of it borders on the lake of Titicaca, that collection of waters is alfo called the lake of Chucuito. The extent of this province from N. to S. is between 26 and 28 leagues, its temperature is in general cold and very unpleafant; the frofts continuing one half of the year, and during the other half either fnow or hail is continually falling. Accordingly the only efculent productions of the vegetable kingdom are the papas and quinoas. The inhabitants, however, have a very beneficial trade in cattle, which abound in this jurifdiction, by falting and drying their flefh. The traders who carry it to the coaft exchange it for brandy and wine, and thofe who go to Cochabamba carry alfo papas and quinoas, which they barter for meal. The mountains in this province have filver mines, which formerly produced large quantities of this metal, but they are at prefent totally abandoned.

Chucuito, *lake of*, otherwife called the lake of *Titi-caca*, lies between the provinces comprehended under the general name of Calloa, and is of all the known lakes of America much the largeft. Its figure is fomewhat oval, inclining nearly from N.W. to S.E.; its circumference is about 80 leagues, and the water in fome parts 70 or 80 fathoms deep. Ten or twelve large rivers, befides a great number of fmall ftreams, difcharge themfelves into it. The water, though neither bitter nor brackifh, is turbid, and has a tafte fo naufeous that it cannot be drank; it abounds with fifh of two oppofite kinds; the one large and palatable, which the Indians call "Suchis;" the other, fmall, infipid, and bony, termed long fince by the Spaniards "Boyas." It has alfo a great number of geefe and other wild fowl, and the fhores are covered with flags and rufhes, the materials of which the bridges are made. As the weftern borders of this lake are called Chucuito, thofe on the eaft fide are diftinguifhed by the name of "Omafcuyo." It contains feveral iflands, among which is one very large, and was anciently one mountain, but fince levelled by order of the Incas. It however gave to the lake its own name of Titicaca, which in the Indian language, fignifies a mountain of lead. In this ifland the firft Inca, Mango Capac, the illuftrious founder of the empire of Peru, invented his political fable, that the Sun, his father, had placed him, together with his fifter and confort, Mama Oillo Huaco, there, enjoining them to draw the neighbouring people from the ignorance, rudenefs, and barbarity, in which they lived, and humanize them by cuftoms, laws, and religious rites, dictated by himfelf; and in return for the benefits refulting from this artful ftratagem, the ifland has been confidered, by all the Indians, as facred; and the Incas determining to erect on it a temple to the fun, caufed it to be levelled, that the fituation might be more delightful and commodious.

This was one of the moft fplendid temples in the whole empire. Befides the plates of gold and filver with which its walls were magnificently adorned, it contained an immenfe collection of riches, contributed by all the inhabitants of provinces which depended on the empire, who were under an indifpenfable obligation of vifiting it once a year and offering fome gift. Thus were accumulated gold, filver, and jewels. The Indians when they perceived the rapacious violence of the Spaniards, are thought to have thrown this immenfe mafs of riches into the lake. Towards the fouth part of the lake is a kind of bay formed by the approach of the banks to each other; and this bay terminates in a river called "Al Defaguadero," or the drain, and afterwards forms the lake of Pavia, which has no vifible outlet, but from which the water is difcharged by a fubterraneous paffage.

CHUDLEIGH, in *Geography*, is a fmall but neat town in Devonfhire, England, for which the privilege of holding a weekly market, and two annual fairs, was obtained by the bifhops of Exeter, who had a magnificent palace about a quarter of a mile to the fouth, part of which yet remains. Lord Clifford, of Ugbrooke, now poffeffes the manor, which formerly abounded with wood; the north-eaft fide of the parifh ftill retains the name of Chudleigh-woods. The vicinity prefents fome very beautiful views; and is celebrated for cyder. The town principally confifts of one long ftreet, at the weftern end of which is a fmall white-wafhed church, containing fome monuments of the Courtenay family. Chudleigh is fituated 182 miles W. of London, and contains 414 houfes; the number of inhabitants being 1786. The market is held on Saturdays.

Chudleigh *Rock*, about half a mile from the town, is, in the opinion of Mr. Polwhele, "one of the moft ftriking inland rocks in the ifland." Viewed from the weft, it difplays a bold broad front, almoft perpendicular; which, to appearance, is one folid mafs of marble; from the fouth-eaft, a hollow opens to the fight, with an impetuous ftream, which rufhes over the rude ftones that impede its paffage, and forms a romantic water-fall, which

"In loud confufion o'er the broken fteep
Abruptly pours, and dafhes down the deep."

Midway down the cliff, is a large cavern, whofe gloomy receffes the traditions of the peafantry have affigned for the habitation of Pixies, or Pifgies, a race of fupernatural beings, or fort of fairies. The entrance to the cavern is by a natural arch, about twelve feet wide and ten in height; the paffage continues nearly of the fame dimenfions for about twenty yards, when it fuddenly diminifhes to fix feet by four, and, ftill gradually decreafing in fize, extends about fifteen yards further. Here it expands into a fpacious chamber, which divides and runs off into two different directions; but the rock dropping, neither of them can be purfued to any confiderable diftance.

About one mile fouth-weft of Chudleigh is *Ugbrooke*, the feat of lord Clifford, baron of Chudleigh. This demefne, for internal beauties, furpaffes any in Devon; the park and grounds comprize much beautiful and highly picturefque fcenery; confifting of cluftered woods, rugged rocks, and inequality of furface; they comprehend a fpace of between feven and eight miles in circumference; and abound with oak, elm, afh, and chefnut, of the moft luxuriant growth. Hiftory, &c. of Devonfhire, by Polwhele, fol.

CHUDUCA,

CHUDUCA, in *Ancient Geography*, a town of Asia, placed by Ptolemy in Babylonia.

CHUGANSERAI, in *Geography*, a town of Asia in the soubah of Cabul, or, according to the emperor Baber, at the western extremity of Caferistan, on a river of the same name; 80 miles N.E. of Cabul. N. lat. 34° 55′. E. long. 70° 8′.

CHUGANSERAI, a river of Asia, near the above-mentioned town, which flows from the N.E. quarter in respect of the town, and from behind, *i.e.* from the north of Bijore, and joins the Bacan river, in the district of Kameh, where their united streams take an easterly course.

CHUKA, or CHOOKA, a castle in the country of Bootan, which is a large square building, placed on elevated ground, and having one entrance into it by a flight of steps, and through a spacious gate-way, with large heavy doors; it is built of stone, and the walls are of a prodigious thickness. This castle is seated on the river Tehintchieu, and at a short distance above it is a chain-bridge, called Chuka-chazum, stretched over the river, and admitting only one horse to pass over it at a time. It swings as you tread upon it, reacting at the same time with a force that impels you, every step you take, to quicken your pace. On the five chains that support the platform are placed several layers of strong coarse mats of bamboo, loosely put down, so as to play with the swing of the bridge; and a fence on each side, formed of the same materials, contributes to the security of the passenger. Capt Turner, in his "Account of an Embassy to Tibet," has given a drawing of the plan and sections of this bridge, constructed from a measurement of its different parts, together with a perspective view of it, and the adjacent scenery. There is a similar bridge over the river Tees, described by Hutchinson in his "History and Antiquities of Durham." The superstitious inhabitants consider this bridge as somewhat more than mere human production, and ascribe it to the dewta Tchuptihup, whose origin and history cannot be traced with any degree of certainty. Tradition says, that this distinguished person, in his flight from Bootan to the country of the Racusses, whose ruler he put to death, and the government of which he assumed, passed over a mountain at some distance from Chuka, through a chasm in the solid rock of the depth of 18 or 20 feet, just wide enough to admit a man on horseback, and that in scrambling over the rock, he left a deep impression of his hands and feet upon the stone. The vestiges are still pointed out, and the people are credulous enough to believe the story. This mountain communicates with that which is opposite to it by a very curious and simple bridge, constructed for the accommodation of single passengers. It consists of two large ropes made of twisted creepers, stretched parallel to each other, and encircled with a hoop. The passing traveller places himself between the ropes, and sitting down on the hoop, seizes one rope in each hand, and thus sliding himself along, crosses an abyss which cannot be viewed without shuddering. By this mode of passing from one mountain to another, travellers save a laborious journey of several days. In the vicinage of Chuka are many well cultivated fields of wheat and barley. It is distant from Murichom about 18 miles. N. lat. 27° 15′. E. long. 89° 35′.

CHUKOTSKIJA, a province of Siberia, and the most easterly of the dominions of Russia, extending from 63° to 73° 20′ N. lat. and from 156° 14′ to 189° 14′ E. long. See TSCHUTSKI.

CHULAPU, is one of the deserts of the Andes in South America, in which the Spanish astronomers, deputed to measure the meridian, placed one of their signals.

CHULLABIS, in *Ancient Geography*, a town of Africa, according to St. Augustine.

CHULUTECA, or XERES, in *Geography*, a town of Mexico, in the province of Guatimala, on the N. side of the river Fonseca. N. lat. 13° 20′. W. long. 88° 6′.

CHUMANA, or PHUMANA, in *Ancient Geography*, a town of Chaldæa.

CHUMBI-VILCAS, in *Geography*, a jurisdiction of South America, in the diocese of Cusco; which extends in some parts above 30 leagues, and has different temperatures of air, great quantities of corn and fruits, and large herds of cattle, together with some mines of silver and gold.

CHUMBUL, one of the most considerable rivers in Hindoostan. Taking its rise near the ancient city of Mundu, in the heart of the province of Malwa, within 15 miles of the Nerbudda, it pursues a north-easterly direction, and after washing the city of Kotah, and receiving the tribute of many subordinate streams, at length empties itself into the Jumna, 20 miles below Etawa. The whole length of its course is about 440 miles. The village of Keyterce stands on its southern bank, and the width of its channel is here $\frac{3}{4}$ of a mile.

CHUMDA-TCHIEN, a river of Asia, in the country of Bootan, which flows from the east and discharges itself into the Tehintchieu, near its junction with the Patchieu.

CHUMLEIGH, or CHIMLEIGH, is a small market-town, in Devonshire, England, situated on the north bank of the river Dart. The church was formerly collegiate, and four prebends are still annexed to the rectory. This structure was greatly damaged in July 1797, by a tremendous storm; in which the lightning acted with such amazing force, that a stone, upwards of 200 pounds in weight, was carried from the south-east pinnacle completely over the tower, without touching it. The number of houses in this parish is 296: of inhabitants 1333. Chumleigh is 194 miles W. from London; has a weekly market on Thursday; and an annual fair.

CHUMULAREC, the name of a range of mountains in the southern part of Tibet, about N. lat. 28° 5′, and 89° 20′ E. long.; which is covered with snow all the year. Many rivers originate in these mountains, and flow towards the south, with a rapid descent, through Boutan into Bengal; while others, taking a northerly direction, fall into the Berhampooter, and are conveyed with it, to a junction, in the neighbourhood of the sea, with the waters which flow in a contrary course from the same general source. This fact proves that this part of Little Tibet constitutes the highest point of land.

CHUN, or CUN, in *Ancient Geography*, a town of Asia in Syria, conquered by David, and mentioned in the book of Chronicles.

CHUNAGUR, or JUNAGUR, in *Geography*, a city and fortress of Hindoostan, in the heart of the peninsula of Guzerat.

CHUNAM. See *Calcareous* CEMENT.

CHUNAR, a fortress of Hindoostan, in the country of Benares, situated on a rock on the south side of the Ganges, and surrounded with walls and towers; ceded to the English by the nabob of Oude; 13 miles S. of Benares. N. lat. 25° 10′. E. long. 83° 5′.

CHUNAUB, or JENAUB, a river of the Panjab in India, the *Acesines* of Alexander, and the *Sandabalis* of Ptolemy. This river is larger than the Behut, and has its sources more remote; for it rises on the east of Kishtewar and has two distinct heads. Its general course is remarkably straight from N.E. to S.W.; and after leaving Jummoo, passes through a flat country, gradually approaching the Behut. The junction of these rivers is effected with great violence and noise, and no less danger to navigators; and

this

this circumftance is peculiarly noticed both by the hiftorians of Alexander and of Timur. The fpace between the Chunaub and Behut is no where more than 30 geographical miles, within the limits of the Panjab. The fpace between the Rauvee and Chunaub, at their entry on the plains, is about 54 geographical miles; and they gradually approach each other, during a courfe of feven miles. The junction of the Rauvee with the Chunaub, or rather the Chenaub and Behut collectively, is effected nearly midway between Toulamba and Moultan. The Ayin Acbaree allows 27 coffes between the junction of the Behut and Chunaub, and that of the Rauvee with the Chunaub: but, from circumftances, major Rennell concludes, that the diftance muft be applied to the *courfe* of the river, not to the road by land. When thefe three rivers are united, they form a ftream equal to the Indus itfelf, at the place of confluence; which is from 20 to 30 miles below Moultan.

CHUNCOA, in *Botany*, a barbarous name of a tree borrowed from the natives by Pavon, who found it in woods near the river of Amazons, and adopted by Juffieu as a diftinct genus with the following character: *Cal.* five-cleft, with a fpreading border. *Stam.* ten. *Peric.* capfule, five-cornered; angles winged, the two oppofite ones larger. *Seed* one, not crowned. *Leaves* alternate, diftant. *Flowers* in axillary fpikes, hermaphrodite at the bafe, male near the top. The authors of Flor. Peruv. call it gimbernatia, and have figured it under that name in pl. 36. of their work. It would arrange under polygamia monœcia of the Linnæan fyftem, and is placed in the natural order elæagni by Juffieu.

CHUNDNAH, in *Geography*, one of the fubordinate branches of the Ganges, which feparates from it at Moddapour, and terminates in the Hooringolla. This is the only branch of the Ganges that is at all times navigable.

CHUNG, a town of China, of the third rank, in the province of Pe-tche-li; 20 miles N.E. of Peking.

CHUNGAR, in *Ornithology*. In the hiftory of Timur Beck, mention is made of a fine bird of Tartary, called chon-kui, that was prefented to Gengis-khan by the ambaffadors of Kadjak. The bird appears to be unknown to the European naturalifts. Sonnini fuppofes it may be the Turkifh *chungar*, and therefore a heron or bittern. Others affirm that it is a bird of prey, which, being ornamented with a number of precious gems, is prefented by dependent ftates as a mark of homage. The Ruffians, as well as the Tartars of the Crimea, Sonnini tells us, are obliged by virtue of certain treaties, with the Ottoman empire, to prefent one of thofe birds decorated with a certain number of diamonds every year to the Porte.

CHUNI, in *Ancient Geography*, a people of Sarmatia, placed by Ptolemy between the Bafternæ and Roxolini.

CHUN-KING, a city of China, of the firft rank, in the province of Se-tchuen, comprehending within its diftrict nine cities, of which two are of the fecond rank; 760 miles S.S.W. of Peking. N. lat. 30° 50'. E. long. 105° 44'.

CHUN-LIEOU, a town of Afia, in the kingdom of Corea; 25 miles E.N.E. of Koang-tcheou.

CHUNNA, in the *Salic Laws*, is ufed for an hundred; or rather an hundred pence or *denarii*; the pecuniary penalties of that law are eftimated by *chunnæ*, and reduced to *folidi*, by reckoning forty *denarii* to the *folidum*.

CHUN-NGHAN, in *Geography*, a town of China, of the third rank, in the province of Tche-kiang; 11 leagues N. of Kiu-tcheou.

CHUN-NING, a city of China, of the firft rank, in the province of Yun-nan; 420 leagues S.W. of Peking. N. lat. 24° 37'. E. long. 99° 44'.

CHUN-TCHAN, a town of China, of the third rank, in the province of Fo-kien; 30 miles W.N.W. of Yen-ping.

CHUN-TCHUEN, a town of Afia, in the kingdom of Corea; 22 miles S.E. of Han-tcheou.

CHUN-TE, a city of China, of the firft rank, in the province of Pe-tche-li; 200 miles N.N.E. of Peking. This city has but a fmall diftrict; for there are only nine cities of the third clafs under its jurifdiction; but they are all very populous. The adjacent country is pleafant and fertile; on account of the number of lakes and rivers that water and refrefh it. Its craw-fifh are celebrated; and it produces a fine delicate kind of fand, ufed in polifhing precious ftones, which is fold all over the empire. It abounds alfo with touch-ftone, which is reckoned the beft in China. N. lat. [illegible] E. long. 114° 19'.

CHUN-TIAN, a town of Afia, in the kingdom of Corea; 27 miles S.S.E. of Koang-tcheou.

CHUN-YAN, a town of Afia, in the kingdom of Corea; 20 miles S. of Han-tcheou.

CHUPKA, or KEPTA, a mountain of Bootan, fomewhat more northerly than the valley of Punugga, having half-way up its fide a caftle, in a bleak, but beautifully romantic fituation; the mountains in its neighbourhood appearing to captain Turner the higheft which he had feen in Bootan.

CHUPMESSAHITES, a fect among the Mahometans who believe that Jefus Chrift is God, and the true Meffiah, the redeemer of the world; but without rendering him any public, or declared worfhip.

The word, in the Turkifh language, fignifies "Protector of the Chriftians.

Ricaut fays, there are abundance of the Chupmeffahites among the people of fafhion in Turkey, and fome even in the feraglio.

CHUPUAH, in *Geography*, a town of Hindooftan, in the country of Bahar, on the north coaft of the Ganges; 25 miles N.W. from Patna.

CHUQUIRAGA, in *Botany*, a barbarous name given by the Peruvians to a fyngenefious plant, and adopted by Juffieu and La Marck as a generic one. Juff. 178. Lam. Illuf. Pl. 691. Nat. Ord. *Corymbyferæ*, Juff.

Gen. Ch. *Cal.* large, top-fhaped, compofed of very numerous imbricated fcales; the outward ones growing gradually fmaller. *Flowers* flofculous; florets numerous, very long, nearly entire at their borders; anthers long, with two briftles at their bafe; ftigma one; down feathered, long; receptacle villous.

A branched fhrub. *Leaves* rigid, like thofe of rufcus, acuminate, alternate, denfely imbricated. *Flowers* folitary, terminating the branches. Nearly allied to mutifia, but not radiate; perhaps ftill more nearly allied to the cinarocaphalæ. Defcribed from a dried fpecimen in the herbarium of Jof. Juffieu.

CHURAQUER, in *Geography*, a town of Armenia; 48 miles W. of Erivan.

CHURASCH, a town of Arabia; 44 miles S. of Saade.

CHURCH, an affembly of perfons united by the profeffion of the fame Chriftian faith, and the participation of the fame facraments. Bellarmin, and the Romifh divines, to this definition add, "Under the fame pope, fovereign pontiff, and vicar of Jefus Chrift on earth:" in which circumftance it is that the Romifh and Reformed notions of church differ.

Amelotte, and others, make a vifible head, or chief, effential to a church: accordingly, among the Catholics, the pope; in England, the king; are refpectively allowed heads of of the church. Biſhop Hoadly ſets aſide the notion of a viſible head: Chriſt alone, according to him, is head of the church; which poſition he has maintained, with great addreſs, in a celebrated ſermon before king George I. on theſe words, "My kingdom is not of this world;" and in the ſeveral vindications of it. To this purpoſe, he ſays, that as the church of Chriſt is the kingdom of Chriſt, he himſelf is king; and in this it is alſo implied, that he is himſelf the ſole lawgiver to his ſubjects, and himſelf the ſole judge of their behaviour, in the affairs of conſcience and eternal ſalvation. In theſe points he hath left behind him no viſible, or human authority; no vicegerents, who can be ſaid properly to ſupply his place; no interpreters, upon whom his ſubjects are abſolutely to depend; no judges over the conſciences or religion of his people. Mr. Locke, in his "Letters concerning Toleration," deſcribes a church as a voluntary ſociety of men, who join themſelves together, of their own accord, for the public worſhip of God, in ſuch a manner as they judge acceptable to him, and effectual to the ſalvation of their ſouls. Nobody, he ſays, is born a member of any church; otherwiſe the religion of parents would deſcend to children, by the ſame right of inheritance as their temporal eſtates, and every one would hold his faith by the ſame tenure as he holds his lands; than which nothing can be imagined more abſurd. As the entrance of a perſon into any particular church is voluntary, ſo is alſo his continuance in it. No member of any religious ſociety, ſays Mr. Locke, can be tied with any other bonds but what proceed from the certain expectation of eternal life. A church, then, is a ſociety of members voluntarily uniting to this end. This author further adds, that things, never ſo indifferent in their own nature, when they are brought into the church and worſhip of God, are removed out of the magiſtrate's juriſdiction; becauſe in that uſe they have no connection at all with civil affairs. The only buſineſs of the church is the ſalvation of ſouls: and it noways concerns the commonwealth, or any member of it, that this, or the other ceremony be there made uſe of. Neither the uſe, nor the omiſſion of any ceremonies in theſe religious aſſemblies, does either advantage or prejudice the life, liberty, or eſtate of any man.

The term *eccleſia*, εκκλησια, ſynonymous with our church, is uſed in the Greek and Latin profane authors for any kind of public aſſembly called together upon any public buſineſs, to enact laws, &c. (ſee Æſchines, paſſim, and Lucian, who uſes the words Θεων εκκλησια, *q. d.* an aſſembly of the gods); and the term was even uſed for the place where the aſſembly was held. The ſacred and eccleſiaſtical writers ſometimes alſo uſed it in the ſame ſenſe; but ordinarily they reſtrain the term to the Chriſtians; as the term *ſynagogue*, which originally ſignifies nearly the ſame thing, is in like manner reſtrained to the Jews.

Thus, in the New Teſtament, the Greek εκκλησια ſignifies, almoſt always, the aſſembly of the faithful diffuſed over the whole earth, as Epheſ. v. 24. or the faithful of a particular city or province, as Acts, xi. 22. xv. 22. 2 Cor. viii. 1. or even of a ſingle family, as Rom. xvi. 5.

For the meaning of the term εκκλησια, as it was applied by the ſacred writers, ſee alſo Acts, xix. 32. 40. 1 Cor. xiv. 23. Phil. iv. 15. Heb. xii. 23. From the ſeveral places above cited it appears, that the congregation, and not the place, forms the ſcripture idea of a church. The Hebrew word קהל exactly correſponds to the Greek εκκλησια, and is commonly rendered by it in the Septuagint, the only Greek tranſlation of the Old Teſtament in uſe in the time of our Saviour. Its idiom and phraſeology were conſequently become the ſtandard, in all matters that concerned religion, to all the Jewiſh writers who uſed the Greek language, and who were commonly diſtinguiſhed by the name of Helleniſts. From them the term was originally borrowed by the penmen of the New Teſtament. From their manner of uſing it, therefore, the general meaning of the word is to be ſought. But though the phraſes כל קהל ישראל in Hebrew, and πασα ἡ εκκλησια Ισραηλ in Greek, the whole church of Iſrael, do frequently occur in the Old Teſtament, there is not a ſingle paſſage in which they are not confeſſedly equivalent to the phraſes כל גוי ישראל, and παν το εθνος Ισραηλ, all the nation of Iſrael. The ſame may be ſaid of the phraſes קהל אלהים and עם אלהים, ἡ εκκλησια Θεȣ and ὁ λαος Θεȣ, the church of God, and the people of God. A diſtinction between theſe would have been pronounced by them inconceivable, as being a diſtinction between the church and its conſtituent members. In the Latin tranſlation, called the Vulgate, the date of which is about the beginning of the 5th century, the Greek word is commonly retained, having been long before naturalized among Chriſtians. Accordingly, they rendered theſe phraſes in the Old Teſtament "omnis eccleſia Iſrael," and "eccleſia Dei." Our Engliſh tranſlators, however, have never admitted the word "church" into their verſion of the Old Teſtament, notwithſtanding the frequent uſe they have made of it in the New. They have always rendered the Hebrew word קהל, by the Engliſh words, congregation, aſſembly, or ſome ſynonymous term. Either of theſe Engliſh terms is well adapted to expreſs the ſenſe of the Hebrew: and they were altogether as fit for expreſſing the ſenſe of the word εκκλησια in the New Teſtament as of the word קהל in the Old; the former being the term by which the latter had been rendered almoſt uniformly in the Septuagint, and which had been employed as equivalent by all the Helleniſt Jews. In order to preſerve uniformity, our tranſlators ought conſtantly to have rendered the original expreſſion either "church" in the Old Teſtament, or "congregation" in the New. Terms ſo perfectly coincident in ſignification, as theſe Hebrew and Greek names are, ought to have been tranſlated by the ſame Engliſh word. Indeed, our tranſlators do not refuſe the title of church to the commonwealth of Iſrael, when an occaſion for giving it occurs in the New Teſtament, though they have not availed themſelves of a ſimilar occaſion in the Old. Thus they have rendered the words of Stephen, who ſays, ſpeaking of Moſes, Acts, vii. 38. "This is he that was in the church in the wilderneſs;" Ουτος εστιν ὁ γενομενος εν τη εκκλησια εν τη ερημω. We do not find, however, ſays Dr. Campbell, in his "Eccleſiaſtical Hiſtory" (vol. i. p. 323.), in the uſe of either the Greek word in the New Teſtament, or of the correſpondent word in the Old, any veſtige of an application of the term to a ſmaller part of the community, their governors, paſtors, or prieſts, for inſtance, as repreſenting the whole. The only paſſage that has been alleged, with any appearance of plauſibility, in favour of this application, is Matt. xviii. 17, where our Lord, in the directions he gives for removing offences between brethren, enjoins the party offended, after repeated admonitions in a more private manner have proved ineffectual, to relate the whole to the church, ειπε τη εκκλησια; but Dr. Campbell aſks, "by what rule of ſound criticiſm can we arbitrarily impoſe here on the word "church" the ſignification of church repreſentative, a ſignification which we do not find it bears in one other paſſage of ſcripture?" But that the meaning of the word is here, as in other places, no more than congregation, and that it ſhould have been ſo rendered, he argues from the conſideration that our Lord gave theſe directions during the ſubſiſtence of the Moſaic eſtabliſhment; and if we believe that he ſpoke intelligibly, or with a view to be underſtood, we muſt believe alſo that he uſed the word in an

acceptation

acceptation with which the hearers were acquainted. All the then known acceptations of the name εκκλησια, were these two, the whole Jewish people, and a particular congregation. The scope of the place sufficiently shews, it could not be the former of these senses, and it must therefore be the latter. What further confirms this interpretation is, that the Jews were accustomed to call those assemblies, which met together for worship in the same synagogue, by this appellation; and had, if we may believe some learned men conversant in Jewish antiquities, a rule of procedure similar to that here recommended, which our Lord adopted from the synagogue, and transplanted into his church. This learned writer proceeds to adduce another collateral and corroborative evidence, that by εκκλησια is here meant not a representative body, but the whole of a particular congregation; and this is the actual usage of the church for the first 300 years. As far down as Cyprian's time, about the middle of the third century, when the power of the people was on the decline, it continued to be the practice, that nothing relating to matters of scandal and censure could be concluded without the consent and approval of the congregation. Upon the whole it seems to be evident that the term *church*, denoting, according to its etymology, no more than society or assembly, is sometimes used in the New Testament, with obvious analogy to the common use, to signify the whole community of Christians, considered as one body, of which Christ is denominated the head, and sometimes only a particular congregation of Christians. When this word is limited, or appropriated, as it generally is in the New Testament, by its regimen, as τȣ θεȣ, τȣ κυριȣ, τȣ χριςȣ, or by the scope of the place, it is always to be explained in one or other of the two following senses. It denotes either a single congregation of Christians, or the whole Christian community; nor can we hardly ever be at a loss to know from the context which of the two is implied. The former acceptation of the term is sometimes evident from the words in construction, as της εκκλησιας της εν Κεγχρεαις, and τη εκκλησια τȣ θεȣ τη εν Κορινθω, or the like. In the latter sense it ought always to be understood, when we find nothing in the expression, or in the scope of the passage, to determine us to limit it; *e.g.* in the following, Επι ταυτη τη πετρα οικοδομησω μȣ την εκκλησιαν. Ὁ κυριος προσετιθεις τȣς σωζομενȣς καθ' ἡμεραν τη εκκλησια. In this last acceptation of the word, for the whole body of Christ's disciples, wheresoever dispersed, it came afterwards to be distinguished by the epithet καθολικη. Accordingly, they said ἡ εκκλησια ἡ καθολικη, the catholic or universal church. But, it has been alleged, that in any intermediate sense, between a single congregation and the whole community of Christians, no single instance can be brought of the application of the word in sacred writ. We speak now, indeed (and this has been the manner for ages), of the Gallican church, the Greek church, the church of England, the church of Scotland, as of societies independent and complete in themselves. Such a phraseology was never adopted in the days of the apostles. They did not say, the church of Asia, or the church of Macedonia, or the church of Achaia, but the churches of God in Asia, the churches in Macedonia, the churches in Achaia. The plural number is invariably used when more congregations than one are spoken of, unless the subject be the whole commonwealth of Christ. This is not only the mode of expression adopted by the sacred writers, but it is the constant usage of the term in the writings of ecclesiastical authors for the two first centuries: allowing for one exception to the contrary, which occurs in the epistles of Ignatius. This language is also conformable to the usage, in relation to this term, which had always obtained among the Jews. The whole nation, or commonwealth of Israel, was often denominated πασα ἡ εκκλησια Ισραελ; and after the revolt of the ten tribes, when they ceased to make one people or state with the other two, we hear of πασα ἡ εκκλησια Ιȣδα. This is the large or comprehensive use of the word above noticed. With regard to the more confined application, the same term εκκλησια was also employed to denote a number of people, either actually assembled, or wont to assemble in the same place. Thus, all belonging to the same synagogue were called indifferently εκκλησια, or συναγωγη, as these words in the Jewish use were nearly synonymous. The limitation of the term "church" to the clergy and the ecclesiastical judicatories, and the claims of independency advanced by these, as well as certain claims of power and jurisdiction, in some things differing, and in some things interfering with the claims of the magistrate, arose after the establishment of the Christian religion under Constantine; and hence a distinction subsisted, in the Christian community, at an early period, between the church and state.

We may here remark, that it is doubtful whether the word εκκλησια ever occurs in the New Testament in a sense, in which, indeed, the word "church" is very common with us, as a name for the place of worship. There are two passages, which seem to convey this sense; and they both occur in the 11th chapter of the 1st epistle to the Corinthians. The 1st is v. 18, "when ye come together in the church," συνερχομενων ὑμων εν τη εκκλησια. Here, however, the word is susceptible of another interpretation, as a name for the society. Thus we say "The lords spiritual and temporal, and the commons in parliament assembled," where parliament does not mean the house they meet in, but the assembly properly constituted. The other passage is v. 22. "Have ye not houses to eat and drink in, or despise ye the church of God?" της εκκλησιας τȣ θεȣ καταφρονειτε: where, it is alleged, the opposition of εκκλησια to οικια, the church to their houses, adds a probability to this interpretation. This plea, however, though plausible, is not decisive. The apostle's argument on the contrary hypothesis would stand thus: what can be the reason of this abuse? Is it because ye have not houses of your own in which to eat and drink? Or is it because ye despise the Christian congregation to which you belong? This, though it must be allowed not to convey so exact a verbal antithesis, is, in the judgment of some writers, more in the spirit and style of the New Testament, than to speak of despising stone walls. At length, however, the term εκκλησια, by a common metonymy, the thing contained for the thing containing, came to be universally employed in this acceptation. Among the extraordinary ministers of the Christian church, at the period of its first establishment, we may reckon apostles, prophets, and evangelists, besides those who were endowed with supernatural gifts, and afterwards bishops, presbyters, and deacons. See these several terms.

The word "church," says lord chancellor King (Constitution, Discipline, &c. of the Primitive Church), is both in our modern acceptation, and also in the writings of the fathers, equivocal, having different significations, according to the different subjects to which it is applied. It is often to be understood, 1st, of the "Church Universal," that is, of all those, who, throughout the face of the whole earth, professed faith in Christ, and acknowledged him to be the Saviour of mankind. This is that which they called the "Catholic Church." See Iren. l. i. c. 2. c. 3. Apud Eufeb. l. vi. c. 25. l. vii. c. 10. l. iv. c. 15. 2. The word "church" is frequently to be understood of a "particular church," that is, of a company of believers, who, at one time, in one and the same place, associated themselves together, and concurred in the participation of all the institutions

ſtitutions and ordinances of Jeſus Chriſt, with their proper miniſters and paſtors. Various inſtances of this uſe of the term occur in Irenæus, Cyprian, Ignatius, Origen, &c. 3. The word "church" is ſometimes uſed for the place where a particular church or congregation met for the celebration of divine ſervice; and it is thus uſed by Paulus Samoſatenus, Clemens Alexandrinus, Tertullian, Origen, &c. &c. 4. The word "church" is once uſed by Cyprian for a collection of many particular churches; but when the fathers have occaſion to ſpeak of the Chriſtians in any kingdom or province, they always uſe the plural, "the churches," and never the ſingular, or the church of ſuch a kingdom or province. 5. The word "church" frequently occurs for that which we commonly call the inviſible church, that is, for thoſe who, by a ſound repentance and a lively faith, are actually intereſted in the Lord Jeſus Chriſt; and it is thus uſed by Tertullian, Irenæus, and others of the fathers. 6. The word "church" is frequently to be interpreted of the faith and doctrine of the chuch. It is alſo uſed, according to its original import, for any congregation in general, as we have already ſtated; ſometimes it is applied to any particular ſect of heretics; at other times it is attributed to the orthodox in oppoſition to the heretics; in both which ſenſes it is uſed by Tertullian; ſometimes it is appropriated to the heathen aſſemblies, as by Origen; at other times, in oppoſition to the Jews, it is aſcribed to the believing Gentiles, as by Irenæus: in other places it ſignifies the aſſembly of the ſpirits of juſt men made perfect in heaven, commonly called "the church triumphant," in oppoſition to "the church militant," or the aſſembly of the faithful on earth. To theſe the Catholics add "the church patient," which, according to their doctrine, is that of the faithful in purgatory. Lord King (ubi ſupra) ſays, that he has once found the term "church" denoting the laity only, in oppoſition to the clergy (Επισκοποι και Πρεσβυτεροι, και Διακονοι, και αἱ ἐκκλησιαι τȣ Θεȣ, Euſeb. l. vii. c. 30.): and once ſignifying only Chriſt as the head of the faithful (Eccleſia veri Chriſtus, Tertullian, de Pœnit. p. 302.) After all, this learned writer obſerves, that the uſual and moſt common acceptation of the word is that of a particular church, that is, a ſociety of Chriſtians, meeting in one place, under their proper paſtors, for the performance of religious worſhip, and the exerciſe of Chriſtian diſcipline.

The conſtituent parts of a particular church are the people, who compoſe the body of it, and thoſe perſons who are ſet apart for religious and eccleſiaſtical employments, or, according to our ordinary dialect, the clergy and laity; which is an early diſtinction, being mentioned by Clemens Romanus (Epiſt. 1. ad Corinth.) and after him by Origen (Homil. 11. in Jerem.) and ſeveral others. See Clergy, Bishop, &c.

Every particular church, in ancient times, poſſeſſed the power of exerciſing diſcipline on its own members, without the concurrence of other churches. Accordingly we find, that the exerciſe of this power was formally decreed by two African ſynods, recorded apud Cyprian. Epiſt. 55. § 16. and Epiſt. 72. § 3. Nevertheleſs, a particular church was not the whole church of Chriſt, but only a part or member of the church univerſal; and we therefore find, that though the labours and inſpection of the biſhops were more peculiarly reſtricted to their own pariſhes, yet, as miniſters of the univerſal church, they employed a general kind of inſpection over other churches alſo. Cyprian, Epiſt. 67. § 6. Ed. 29. Euſeb. lib. vii. c. 9. See Council.

With regard to the unity of the church univerſal, in primitive times, the learned author, whom we are now citing, ſhews, that it did not conſiſt in an uniformity of rites and cuſtoms, nor in an unanimity of conſent to the non-eſſential points of Chriſtianity; but it conſiſted in an harmonious aſſent to the eſſential articles of religion, or in an unanimous agreement in the fundamentals of faith and doctrine. If we conſider the word "church," collectively, as denoting a collection of many particular churches, in which ſenſe it is once uſed by Cyprian; then its unity may have conſiſted in a brotherly correſpondence with, and affection towards each other, which they demonſtrated by all outward expreſſions of love and concord. See Schism and Heresy.

The worſhip of the primitive church conſiſted in the reading of the Holy Scriptures, the ſinging of pſalms and hymns, the preaching of the word, and public prayers. To theſe acts of public ſervice, they added the adminiſtration of baptiſm and the Lord's Supper. See each of theſe articles.

In adverting to the articles of the eſtabliſhed church in our own country, we find (art. 19.) that "the viſible church of Chriſt" is defined to be a congregation of faithful men, in the which the pure word of God is preached, and the Sacraments be duly adminiſtered according to Chriſt's ordinance, in all thoſe things that of neceſſity are requiſite to the ſame." The expreſſion of "the viſible church of Chriſt," ſeems here to be uſed in contradiſtinction to the myſtical or inviſible church of Chriſt; which latter conſiſts of thoſe perſons who have truly believed and obeyed the goſpel, and who are conceived, although they have lived at different periods, to be united into one body, which is called myſtical or inviſible; not only becauſe they are not now all upon earth, but becauſe the qualities and properties, which gave them a claim to be members of this bleſſed ſociety, were never the objects of ſenſe, and could not be judged of by men from merely external circumſtances. Whereas, "the viſible church," in its moſt extenſive ſenſe, may include all perſons who are or have been, by outward profeſſion, Chriſtians, whether they have or have not believed all the doctrines, or obeyed all the precepts of the goſpel. This may be called the viſible Catholic church. But in the article, above cited, "the viſible church" is uſed in a more limited ſenſe, and comprehends only the Chriſtians of one country or city, or of one perſuaſion; thus, towards the cloſe, it mentions the church of Jeruſalem, of Alexandria, of Antioch, and of Rome; and in like manner we often ſpeak of the church of England, of Holland, of Geneva, and of the Lutheran church; and all theſe different churches are parts of the viſible Catholic church. "The adherence," ſays Dr. Tomline, biſhop of Lincoln, (Elements of Chriſtian Theology, vol. ii. p. 325.) "to the fundamental principles of the goſpel is ſufficient to conſtitute a viſible church; although every doctrine it maintains may not be founded in truth, or all the parts of public worſhip agreeable to Scripture. We conſider all men as Chriſtians, or as members of the viſible church of Chriſt, who have been baptized, and profeſs their belief in the divine miſſion of Chriſt, even if their faith be in ſome reſpects erroneous, and their lives unworthy of their holy vocation."

The Chriſtian church, with regard to its local eſtabliſhment, extent, and influence, is frequently divided into *Eaſtern* or *Greek* and *Weſtern* or *Latin*.

The firſt jealouſies between the Greek and Latin churches were excited at the council of Sardis, in the year 347, and a vindictive ſpirit prevailed for a long time between the biſhops of Rome and Conſtantinople, which occaſionally broke out into acts of violence. The ambition and fury of theſe contending prelates grew ſtill more keen and vehement about the time of Leo the Iſaurian, when the biſhops of Conſtantinople, ſeconded by the authority and power of the emperors, withdrew from the juriſdiction of the Roman pontiff many provinces, over which they had hitherto exerciſed a ſpiritual

ritual dominion. However, the schism, or total separation, did not take place till the time of Photius, who was elected patriarch of Constantinople in the year 858 by the emperor Michael, in the place of Ignatius, whom that prince drove from his see and sent into exile. Pope Nicholas I. took part with the exiled patriarch, decreed the election to be unwarrantable in a council held at Rome A. D. 862, and excommunicated Photius. The high-spirited patriarch, respected as the most learned and ingenious person of the age in which he lived, assembled a council at Constantinople, A. D. 866, returned the compliment, and declared Nicholas unworthy of his rank in the church, and of even being admitted to the communion of Christians. The pretext alleged by the Roman prelate, in justification of his conduct, was the innocence of Ignatius; but the secret and moving spring seems to have been a desire of recovering from the Greeks the provinces of Illyricum, Macedonia, Epirus, Achaia, Thessaly, and Sicily, which the emperor and Photius had removed from the jurisdiction of his see. The restitution of these provinces had been demanded by a solemn embassy; but his requisition was treated with contempt, and from hence proceeded his zeal in the cause of justice and of Ignatius. The exiled patriarch was soon after restored to his high station by Basilius, who had paved his way to the imperial throne by the murder of his predecessor; and Photius was confined in a monastery. Photius continued to feed the flame of discord, and, having in the year 866 added the province of Bulgaria to the see of Constantinople, he now endeavoured to engage the oriental patriarch in his dispute, and drew up a violent charge of heresy against the Roman bishops, who had been sent among the new-converted Bulgarians, and against the church of Rome in general. Upon the death of Ignatius in 878, the emperor took Photius into favour, and advanced him again to the patriarchal station from which he had been degraded. The grant of Bulgaria to the Roman see was promised to the pontiff John VIII., by the emperor and Greek patriarch, and Photius was acknowledged by John as his brother in Christ. The emperor and Photius falsified their promise, and refused to transfer Bulgaria to the Roman pontiff. After some subsequent occasions of mutual offence, John was succeeded by Marinus, and a new sentence of excommunication was issued against Photius. This sentence was treated with contempt by the haughty patriarch, who, in 886, was deposed by the emperor Leo from the patriarchal see, and confined in an Armenian monastery, where he died in 891. The death of Photius might have terminated the dispute between the eastern and western churches, if the Roman pontiff had not been regardless of the demands of equity as well as of the duty of Christian moderation. But these imperious lords of the church indulged their vindictive zeal beyond measure, and would be satisfied with nothing less than the degradation of all the priests and bishops who had been ordained by Photius. The Greeks, on the other hand, were shocked at the arrogance of these unjust pretensions, and would not submit to them on any conditions. Hence the dispute between the two churches and their partizans was renewed; religious, as well as civil contests, occurred; and by adding new controversies to the old, the fatal schism took place, which produced a total and permanent separation between the Greek and Latin churches.

The doctrine of the Eastern or Greek church, which is, unquestionably, the most ancient, prevails at this day over a greater extent of country than that of any other church in the Christian world. It is professed through a considerable part of Greece, the Grecian isles, Walachia, Moldavia, Egypt, Nubia, Lybia, Arabia, Mesopotamia, Syria, Cilicia, and Palestine; all which are comprehended within the jurisdiction of the patriarchs of Constantinople, Alexandria, Antioch, and Jerusalem; to these, if we add the whole of the Russian empire in Europe, great part of Siberia in Asia, Astracan, Casan, Georgia, and White Russia in Poland, it will be evident that the Greek church has a greater extent of territory than the Latin, with all the branches that are sprung from it.

The *Greek* or *Eastern Church* may be divided into three distinct communities. The *first* is that of the Greek Christians, who agree, in all points of doctrine and worship, with the patriarch residing at Constantinople, and reject the pretended supremacy of the Roman pontiff. The *second* comprehends those Christians, who differ equally from the Roman pontiff and the Grecian patriarch in their religious opinions and institutions, and who live under the government of their own bishops and rulers. The *third* is composed of those who are subject to the see of Rome.

That society of Christians, that maintains religious communion with the patriarch of Constantinople, is, properly speaking, the Greek, though it assumes likewise the title of the Eastern Church. This society is subdivided into two branches, of which the one acknowledges the supreme authority and jurisdiction of the bishop of Constantinople, while the other, though joined in communion of doctrine and worship with that prelate, yet obstinately refuses to receive his legates or to obey his edicts, and is governed by its own laws and institutions, under the jurisdiction of spiritual rulers, who are independent of all foreign authority.

That part of the Greek church, which acknowledges the jurisdiction of the bishop of Constantinople, is divided, as in the early ages of Christianity, into four large districts or provinces, Constantinople, Alexandria, Antioch, and Jerusalem; over every one of which a bishop presides with the title of patriarch, whom the inferior bishops and monastic orders unanimously respect as their common father. This prelate has the privilege of nominating other patriarchs, though that dignity still continues elective, and of approving the election that is made; nor is any thing of moment undertaken or transacted in the church without his express permission, or his special order. Indeed, in the present decayed state of the Greek churches, whose revenues are small, and whose former opulence is almost annihilated, their spiritual rulers enjoy little more than the splendid title of "Patriarchs," without being in a condition to extend their fame or promote their cause, by any undertaking of signal importance.

The spiritual jurisdiction and dominion of the patriarch of Constantinople are very extensive, comprehending a considerable part of Greece, the Grecian isles, Walachia, Moldavia, and several of the European and Asiatic provinces that are subject to the Turks. The patriarch of Alexandria resides generally at Cairo, and exercises his spiritual authority in Egypt, Nubia, Lybia, and a part of Arabia. Damascus is the principal residence of the patriarch of Antioch, whose jurisdiction extends to Mesopotamia, Syria, Cilicia, and other provinces. In Syria there are three bishops, who claim the title and dignity of patriarch of Antioch. The *first* is the bishop of the Melchites, a name given to the Christians in Syria who follow the doctrine, institutions, and worship of the Greek church; the *second* is the spiritual guide of the Syrian Monophysites; and the *third* is the chief of the Maronites, who hold communion with the church of Rome. This last bishop pretends to be the true and lawful patriarch of Antioch, and is acknowledged as such by, or at least receives this denomination from, the Roman pontiff. Nevertheless, it is certain, that the pope creates at

Rome

Rome a patriarch of Antioch of his own choice, so that the see of Antioch has, at this day, four patriarchs, one from the Greeks, two from the Syrians, and one created at Rome, who is patriarch, *in partibus*, i. e. titular patriarch, according to the signification of that phrase.

The patriarch of Jerusalem comprehends, within the bounds of his pontificate, Palestine, Arabia, the country beyond Jordan, Cana in Galilee, and mount Sion.

The episcopal dominions of these three patriarchs are indeed extremely poor and inconsiderable; for the Monophysites have long since assumed the patriarchal seats of Alexandria and Antioch, and have deprived the Greek churches of the greatest part of their members in all those places where they gained an ascendant. And as Jerusalem is the resort of Christians of every sect, who have their respective bishops and rulers, the jurisdiction of the Grecian patriarch is consequently confined there within narrow limits.

The right of electing the patriarch of Constantinople is vested in the 12 bishops who reside nearest that famous capital; but the right of confirming his election, and of enabling the new-chosen patriarch to exercise his spiritual functions, belongs only to the Turkish emperor. But this institution is subject to the grossest perversion and abuse by the corruption and avarice of the reigning ministers. The power of this patriarch among a people dispirited by oppression, and sunk into the grossest superstition by extreme ignorance, must be, and actually is, very considerable and extensive. Besides, his own prerogatives are numerous; for he not only convenes councils by his own authority; but by the special permission of the emperor, he administers justice and takes cognizance of civil causes among the members of his communion. His influence is maintained, on the one hand, by the authority of the Turkish monarch, and, on the other, by his right of excommunicating the disobedient members of the Greek church. The revenue of this patriarch is drawn particularly from the churches that are subject to his jurisdiction; and its produce varies according to the circumstances of the Greek Christians, whose condition is exposed to many vicissitudes.

The Greeks acknowledge, as the rule of their faith, the Holy Scriptures and the decrees of the first seven *general* councils; but no private person has a right to explain, for himself or others, either the declarations of Scripture, or the decisions of these councils; the patriarch and his brethren being the only persons who are authorised to consult these oracles, and to declare their meaning. The substance of the doctrine of the Greek church is contained in a treatise, entitled "The orthodox Confession of the Catholic and Apostolic Eastern Church," drawn up by Peter Mogislaus, bishop of Kiov, in a provincial council assembled in that city. This confession, originally composed in the Russian language, was translated into Greek, and in the year 1643 publicly approved and adoped by Parthenius of Constantinople, and all the other Grecian patriarchs. It was afterwards published in Greek and Latin at the expence of Panagiota, the Turkish emperor's interpreter, who ordered it to be distributed *gratis* among the Greek Christians; and it was also enriched with a recommendatory letter composed by Nectarius, patriarch of Jerusalem. From this confession it evidently appears, that the Greeks differ widely from the votaries of the Roman pontiff, whose doctrines they reject and treat with indignation in several places; but at the same time it appears, that their religious tenets are equally remote from those of the other Christian societies.

With respect to the doctrine of the Greek church, we have already observed, that it is partly derived from the first 7 œcumenical or general councils, viz. that of Nice, A. D. 325; the first of Constantinople, A. D. 381; that of Ephesus, A. D. 431; that of Chalcedon, A. D. 451; the second of Constantinople, A. D. 553; the third of Constantinople in Trullo, A. D. 680; and the second of Nice, A. D. 787. The Nice and the Athanasian creeds are allowed by them; and they hold the doctrine of the Trinity, but with this qualification, that the Holy Ghost proceeds from the Father only, and not from the Father and the Son. The invocation of saints is alike received in the Greek and Roman communion. The Greek church admits the use of pictures to instruct the ignorant, and to assist the devotion of others by those sensible representations. In the Greek church there are 7 mysteries, or sacraments, as they are called in the Latin church, viz. baptism, the Chrism, or baptismal unction, the eucharist, confession, ordination, marriage, and the holy oil or extreme unction. As to baptism, there is nothing peculiar in it. Chrism is called the unction with ointment, and extreme unction is called the consecration with holy oil. The chrism is a mystery peculiar to the Greek communion, and holds the place of confirmation in the Roman. It immediately follows the immersion at baptism, when the priest anoints the person baptized, on the principal parts of the body with an ointment, consecrated with many curious circumstances for that purpose by a bishop; this ceremony is always used at the reception of a proselyte from any other church whatever. As to the eucharist, it has been disputed whether transubstantiation was the doctrine of the ancient Greek church. The Protestants and the eminently learned and eloquent John Claude, maintain the negative; while the Roman Catholics, especially Arnaud, contend for the affirmative; but whether it was maintained in the ancient Greek church or not, it is the doctrine of the present Russian church; for in the oath every bishop now takes at his consecration, he absolutely swears, that "he believes and understands that the transubstantiation of the body and blood of Christ, in the holy supper, as taught by the eastern and ancient Russian doctors, is effected by the influence and operation of the Holy Ghost, when the bishop or priest invokes God the Father in these words, *and make this bread the precious body of thy Christ.* It is held necessary in this church to mix warm water with the wine, and the lay communicants receive both the elements together; the bread being sopped in the cup; but the clergy receive them separate. Children immediately after baptism may receive the communion. Predestination is a dogma of the Greek church, and a very prevailing opinion among the people of Russia. The Greek church admits prayers and services for the dead as an ancient and pious custom, and even prayers for the remission of their sins; but it disallows the doctrine of purgatory, and determines nothing dogmatically concerning the state and condition of departed souls. It also pays a regard to the relics of saints and martyrs of which too superstitious an use is made. Supererogation, indulgences, and dispensations are utterly disallowed in this church; nor does it affect, like the Latin, the character of infallibility, but like most other churches, it is guilty of pretending to be the only true and orthodox church. The confession, or catechism of Mogislaus, above-mentioned, seems to have been at one time received as the standard of the principles of the Russian church; yet there are many points in it, which the present doctors of the church do not approve, others which they consider as trivial; nor, indeed, do they allow the book to have any authority at all.

Many attempts have been made to unite the Greeks with the Latin or Romish church, and also with the Reformed church; but they have hitherto proved unsuccessful. Nothing

thing more deplorable can be conceived than the ſtate of the greateſt part of the members of the Greek church, ſince their ſubjection to the oppreſſive yoke of the Turkiſh emperors. Since that fatal period, almoſt all learning and ſcience, human and divine, have been extinguiſhed among them. Thoſe of them that are in this abject condition have neither ſchools, colleges, nor any of thoſe literary eſtabliſhments, that ennoble human nature, by ſowing in the mind the immortal ſeeds of knowledge and virtue. This ignorance, that reigns among the Greeks, has the moſt pernicious influence upon their morals. Licentiouſneſs and impiety not only abound among the people, but alſo diſhonour their leaders; the calamities that ariſe from this corruption of manners are deplorably augmented by their endleſs contentions and diviſions. Their religion is a motley collection of ceremonies, the moſt of which are either ridiculouſly trifling or ſhockingly abſurd. Yet they are much more zealous in retaining and obſerving thoſe ſenſeleſs rites, than in maintaining the doctrine, or obeying the precepts of the religion they profeſs.

The Ruſſians, Georgians, and Mingrelians adopt the doctrines and ceremonies of the Greek church; though they are entirely free from the juriſdiction and authority of the patriarch of Conſtantinople. Indeed, this prelate formerly enjoyed the privilege of a ſpiritual ſupremacy over the Ruſſians, to whom he ſent a biſhop whenever a vacancy happened. But towards the concluſion of the 16th century, this privilege ceaſed. The ſervice of the Greek church, as it is performed in Ruſſia, &c. is long and complicated; the greateſt part of it varies every day in the year, and every part of the day, except in the communion office, where the larger part is fixed. They have books in many volumes folio, which contain the hymns and particular ſervices for the ſaints and feſtivals as they occur in the calendar throughout the year; and ſuch is the number of ſaints in this church that every day in the year has ſome ſaint, and frequently one day has ſeveral. They contain alſo particular ſervices for the ſeveral days of the week. The one of theſe, comprized in twelve volumes folio; one volume for each month, is called Μηναιον, Minæon, and the other Οκτωηχος, octoechos, in 2 vols. folio, divided into eight voices or tones, as its name indicates; each tone contains hymns and ſervices for the days of one week, and the whole of which ſerves for eight weeks. The "Common Service" is a book which may be conſidered as a ſupplement to thoſe two, and contains ſervices common to all ſaints, martyrs, biſhops, &c. The "Pſalter and the Hours," employ another volume. The "Book of Prayer or the Service" as it is called, contains the ordinary daily prayers, &c. for the prieſts and deacons in the veſpers, matins, and communion offices. The "Lives of the Saints" are in four volumes folio; theſe are read in pariſh churches, but they are uſually read in monaſteries at the matins or morning ſervice. The "Four Goſpels" make one volume by themſelves. There are alſo extracts from the Old Teſtament, and the epiſtles uſed in the ſervice. The "Ritual or Book of Offices" contains the rites of baptiſm, marriage, the burial-ſervice, &c. Theſe books are all in the Sclavonian language, as is conſequently the whole ſervice. In Ruſſia, at this time, they have ſervice, both in monaſteries and pariſh churches, only three times a day; the veſpers, the matins, and the liturgy or communion. The ſervice of every day begins in the evening of the preceding day, as among the Jews. The greater part of the ſervice of this church conſiſts in pſalms and hymns, which ſhould all regularly, according to the primary inſtitution, be ſung; though on account of the length of the ſervice, ſince the joining many forms together, it became the practice to read the greateſt part of them, eſpecially in pariſh churches; yet ſtill they are read in a ſort of recitative. For other particulars, we refer the reader to Dr. King's "Rites and Ceremonies of the Greek church."

A conſiderable reformation was introduced into the Ruſſian church by the wiſdom and active zeal of Peter I. about the beginning of the 18th century, in conſequence of a ſcheme which was projected towards the cloſe of the century preceding. This great prince made no change in the articles of faith received among the Ruſſians, which contain the doctrine of the Greek church. But he took great pains to have this doctrine explained in a manner conformable to the dictates of right reaſon and the ſpirit of the Goſpel; and he uſed the moſt effectual methods to deſtroy, on the one hand, the influence of that hideous ſuperſtition that ſat brooding over the whole nation; and on the other, to diſpel the ignorance of the clergy and that of the people. In order to accelerate the execution of this laudable plan, Peter became the zealous protector and patron of arts and ſciences; and induſtriouſly endeavoured, by a variety of methods, to excite in his ſubjects a deſire of emerging from their ignorance and brutality, and a taſte for knowledge and the uſeful arts. See his biographical article. In reference to the preſent ſubject we may obſerve, that he extinguiſhed the infernal ſpirit of perſecution; aboliſhed the penal laws againſt thoſe who differed merely in religious opinion from the eſtabliſhed church, and granted to Chriſtians of all denominations liberty of conſcience, and the privilege of performing divine worſhip in the manner preſcribed by their reſpective liturgies and inſtitutions. This liberty, however, was ſo modified as to reſtrain and defeat any attempts that might be made by the Latins to promote the intereſts of popery in Ruſſia, or to extend the juriſdiction of the Roman pontiff beyond the chapels of that communion that were tolerated by law. The Jeſuits were not permitted to exerciſe the functions of miſſionaries or public teachers in Ruſſia; and a particular charge was given to the council, taking cognizance of eccleſiaſtical affairs, to uſe their utmoſt care and vigilance for preventing the propagation of Romiſh tenets among the people. Beſides, a very conſiderable change was introduced into the mode of governing the church. The ſplendid dignity of patriarch was ſuppreſſed; and this ſpirited prince claimed in conſequence of his authority as emperor, an abſolute authority in the church. The functions of this high and important office were intruſted with a council aſſembled at Peterſburgh, which was called the "Holy Synod," and in which one of the archbiſhops, the moſt diſtinguiſhed by his integrity and prudence, was appointed as preſident. The other orders of the clergy continued in their reſpective ranks and offices; but both their revenues and their authority were conſiderably diminiſhed. This council, or college, was appointed in the year 1721, and the emperor declared himſelf head of the church. The patriarchate in Ruſſia expired with Adrian, in the year 1700; and he was ſucceeded by an officer of more limited powers, under the name of exarch, or vicegerent of the patriarchal ſee. The government of the exarchy laſted ſomewhat more than 20 years; and by executing the orders of Peter the Great, led the way to the reformation of the clergy. At length the "Holy Legiſlative Synod" was eſtabliſhed by a ſpecial edict publiſhed through the whole empire. This ſynod or college conſiſted at firſt of twelve members; one preſident, two vice-preſidents, four counſellors, and four aſſeſſors; the 12th was charged with the care of eccleſiaſtical concerns at Moſcow, in a particular office, under the name of the ſynodical chancery, which depended on the ſynod.

The members were taken from the biſhops, archimandrites,

drites, hegumens, and prototypes of the moſt eminent monaſteries and churches. To theſe were ſoon added others, both from the regular and ſecular clergy, who were men of learning and fit to govern the church. In the edict by which Peter founded this eccleſiaſtical college, it is called "the general ſpiritual government;" and in the oath taken by the members, it is expreſsly determined, that no other than the ſovereign ſhould be conſidered as its head. In order to give it a higher eſtimation in the minds of the people, he honoured it with the title of "the holy legiſlative ſynod," a title which formerly belonged to the patriarchs. This ſynod was put upon an equality with the ſenate, and inveſted with the ſame powers. The election of biſhops was entruſted to the ſynod, which nominated two candidates, of whom the ſovereign choſe one. Theſe biſhops were authoritatively inſtructed as to their behaviour, power, and viſitation of their dioceſes, the eſtabliſhment and management of ſchools, and a variety of other particulars. The eccleſiaſtical reformation of Peter comprehended alſo the monks, upon whom the order and welfare of the Ruſſian church very much depended, and likewiſe the ſecular prieſts. See the Appendix to the work above cited.

The Georgians and Mingrelians, or as they were anciently called, the Iberians and Colchians, have declined ſo much ſince the Mahometan dominion has been eſtabliſhed in theſe countries, that they can ſcarcely be ranked in the number of Chriſtians. Theſe nations have a pontiff at their head, called "The Catholic;" they have alſo their biſhops and prieſts; but they are ſo ignorant, avaricious, and profligate, that they are a diſgrace to Chriſtianity.

The eaſtern Chriſtians, who renounce the communion of the Greek church, and differ from it both in doctrine and worſhip, may be comprehended under the two claſſes of *Monophyſites* or *Jacobites*, and *Neſtorians* or *Chaldæans*. See theſe articles.

The *Latin* or *Weſtern Church* comprehends all the churches of Italy, France, Spain, Africa, the North, and all other countries whither the Romans carried their language. In a more reſtricted ſenſe the *Latin* church, in contradiſtinction to the Greek church, denotes

The *Church* of *Rome*, which roſe to a very eminent degree of ſplendour and dominion, and exerciſed for ages an almoſt univerſal authority throughout the weſtern world. The various circumſtances that favoured its firſt advancement, and that contributed to the extent and long duration of its dominion, cannot be minutely detailed within our preſcribed limits. We muſt content ourſelves with briefly noticing ſome of the chief and moſt prominent. Rome, from the firſt foundation of the city, gradually advanced into an empire of ſuch extent, revenue, and permanence, as has been unparalleled in the world, either before or ſince. And from the firſt declenſion of that enormous power, ſhe inſenſibly became the ſeat of a new ſpring of empire, which, though not of equal celebrity with the former, has been much more extraordinary, and perhaps more difficult to be ſurmounted, becauſe it is deeply rooted in the paſſions, prejudices, and intereſts of mankind. Independently of the advantage reſulting from the extent of its ſecular dominion, the votaries of the Romiſh church found their right of ſpiritual empire on the prerogatives which they pretend to have been given by our Lord to the apoſtle Peter, and on the ſucceſſion of their biſhops to that apoſtle, and conſequently to thoſe prerogatives. Againſt theſe pretenſions, however, it has been alleged, that Peter did not poſſeſs the prerogatives which they aſcribe to him, and that their biſhops never had any juſt reaſon for denominating themſelves his ſucceſſors. Indeed, in point of right, whatever might have been the prerogatives of Peter, which were perſonal, and not official, no peculiar privilege can be claimed by any church, as derived from this apoſtle. But if we advert from the queſtion of right to the matter of fact, or the ſpecial relation of the ſee of Rome to the apoſtle Peter, the partiſans of papal ambition have never been able to ſupport their affirmations by any thing that deſerves the name of evidence. It has indeed been queſtioned, whether Peter ever was at Rome. The only ground on which the papiſt builds his aſſertion, that he was in that city, and founded the church in it, is tradition; and ſuch a tradition as muſt appear very ſuſpicious to reaſonable Chriſtians, being accompanied with a number of legendary ſtories, which are totally unworthy of regard. See our biographical article St. Peter. Allowing, however, that Peter ſuffered martyrdom at Rome, his journey thither muſt have been poſterior, not only to the period with which the hiſtory of the Acts concludes, but to the writing of Paul's epiſtles, which are wholly ſilent as to this fact. In this caſe it is manifeſt, that he could not have been the founder, nor even one of the earlieſt inſtructors of the Roman church. Moreover, if we admit that Peter, in the courſe of his peregrinations, viſited Rome, and that he was the founder of that church, yet no ſatisfactory evidence can be offered in order to prove that he was the biſhop of the place, according to the proper acceptation of the term, and that their biſhop, whoever he might have been, was diſtinguiſhed by any prerogative whatever, from any other biſhop. The common opinion leads us, if we ſet aſide the apoſtles, to aſſign to Linus the honour of being firſt biſhop of that ſee, who was ordained before the martyrdom both of Peter and of Paul; and yet the latter, in writing to Timothy, a little before his own death, introduces the name of Linus, notwithſtanding his pretended papal dignity, among other obſcure names, no where elſe to be found in the annals of hiſtory, without any marked diſtinction, and without ſo much as giving the ſovereign pontiff the precedency. Beſides, Paul in his epiſtle to the Galatians (chap. ii. 7, 8, 9.), an epiſtle written from Rome, denominates Peter the apoſtle of the circumciſion, to whoſe care was entruſted the converſion of the Jews, throughout the world, and under this character, his miſſion is contraſted with that of Paul, who is ſtyled, by way of eminence, the apoſtle of the Gentiles. To this reaſoning we may add the teſtimony of hiſtory. Irenæus, in a paſſage quoted from him by Euſebius, (l. v. c. 6.) ſhows clearly, that Peter was not conſidered, in his time, or near the end of the ſecond century, as having been biſhop of the church of Rome, or even as its ſole founder. Many other teſtimonies of a ſimilar kind might be produced, if it were neceſſary in ſo plain a caſe. Pope Innocent, who, about the beginning of the fifth century, appears to have been the firſt that thought of deriving the prerogatives of his ſee from the apoſtle Peter, acknowleges that Antioch, as well as Rome, had been properly the ſee of St. Peter; and that it yields to the ſee of Rome only becauſe Peter had accompliſhed there what he had begun at Antioch. After all, no hiſtorical fact can be more unqueſtionable, than that the origin of the ſuperiority of one epiſcopal ſee over another aroſe from the ſecular diviſion of the empire, and from no other conſideration whatever. Hence the pre-eminence of the ſee of Rome, whoſe biſhop, before the converſion of Conſtantine, had only the precedency among the prelates, as biſhop of the imperial city; but no juriſdiction beyond the bounds of the provinces, lying within the vicariate of Rome, as it was called, which was properly no patriarchate, being but the half of the civil dioceſe of Italy, and conſiderably inferior in extent to ſome of the patriarchates. When Conſtantinople became the ſeat of empire, it acquired correſponding

importance;

importance; and though the first place is given to Rome, in the council of Constantinople, A. D. 381, being that from which the emperor still continued to be named, the second was then given to Constantinople, because it was then an imperial city as well as the other. In short, had Rome never been the imperial city, its pastor never could have raised himself above his fellows. Had it continued the imperial city, he might, and probably would, have had such a primacy as to be accounted the first among the patriarchs, but without any thing like papal jurisdiction over church and state. Another circumstance which contributed to the advancement of the Romish church, was the munificence of the emperors, and the misjudged devotion of some great and opulent proselytes, by means of which its bishops rose from a state of obscurity to the most envied opulence and grandeur. Besides the causes already mentioned, viz. the pretended succession from St. Peter, the superior dignity of the city of Rome, and the opulence of her church, there were several others which co-operated in raising her to that astonishing degree of authority and splendour to which, in the course of a few centuries, she attained. The first of these, which we shall cursorily mention, is the vigilant and unremitting policy which she manifested, at an early period, in improving, for her own aggrandizement, every advantage which rank and wealth could bestow. As soon almost as Christianity had received the sanction of the legislature, the bishops of this city began to aspire after a kind of domination over their brethren, which might in time be rendered universal, analogous to the secular authority lodged in the emperors over the subjects of the empire. The distinctions of presbyter, bishop, primate, and patriarch, favoured their views. Their first acquisition, and with this they were for some time satisfied, was the honour of precedency, or primacy, which was conceded to the bishop of Rome. The council of Sardica, about the middle of the 4th century, encouraged the ambitious schemes of these prelates, by enacting a canon, which ordered, that if any bishop should think himself unjustly condemned by his own provincials and metropolitan, his judges might acquaint the bishop of Rome, who might either confirm their judgment, or order a re-examination of the cause. Of this canon the Romish bishops afterwards availed themselves to the exaltation of their see. Valentinian, not many years afterwards, enacted a law, empowering the bishop of Rome to examine and judge other bishops, so that religious disputes might not be decided by profane and secular judges, but by a Christian pontiff and his colleagues. However, neither the canon of Sardica, nor the rescript of the emperor, produced at first any very extensive effect. But the policy of Rome never relinquished any privilege or prerogative which it once obtained; and whilst it was the primary object to advance the papal power, every other consideration gave way to this. This eminently appeared on occasion of the difference which arose between the Eastern and Western churches in the business of Acacius, who, in a matter of controversy, opposed the Roman pontiff; and hence arose a schism between the oriental and occidental churches, which lasted 35 years, and from which the latter, or rather the see of Rome, derived considerable advantage in its progress towards absolute supremacy. In other controversies that occurred, however trivial in themselves, the church of Rome found that, by possessing the prerogative of deciding, she gained accession of authority. The exercise of this power occasioned appeals to the Roman pontiff, which established and extended his influence. It was by flattery of the emperor Phocas, who murdered his sovereign and family, and thus ensuring his favour, that the Roman pontiffs obtained the revocation of the edict which had conferred the title of "Universal bishop" on the patriarch of Constantinople, and a new decree entailing this title in perpetuity on the occupier of the see of Rome, who was actually vested with the primacy of all the bishops of the empire. With similar views of aggrandizement, pope Zachary, in the middle of the 8th century, assisted, with his council and influence, the usurper Pepin to depose his master and benefactor Childeric, king of France, with all his family, and to possess himself of his crown and kingdom. This favour, Pepin, in the next pontificate, retaliated, by aiding the pope to usurp the imperial dominions in Italy. Indeed, it was a maxim on which the Roman pontiffs very uniformly acted, and particularly sanctioned by Gregory, one of the best of them, that every thing, which served to advance the papal power and secure the supremacy of Rome, might be reckoned just and lawful.

Another circumstance, which deserves to be mentioned, because it tended at an early period to advance the authority of the Roman pontiff, was the following: To the vicarage of Rome belonged 10 provinces, including the islands of Sicily, Corsica, and Sardinia; but as in these there were no metropolitans, the vicar of Rome, or pope, had not only the power of an exarch over the whole 10 provinces, but that also of the primate in every province. In him, therefore, coalesced the metropolitical and patriarchal jurisdictions; and he had the charge, either by himself or his delegates, of ordaining every bishop within the provinces of his vicariate. These rights he gradually extended, as circumstances favoured his views, first to the whole prefecture of Italy, which included West Illyricum, and West Africa; afterwards to all the occidental churches, Gaul, Spain, and Britain; and lastly, as of divine right, and, therefore, unalienable, over the whole Catholic church. It was also a great advantage enjoyed by Rome, in consequence of her vast opulence and rich domains, that she was able to employ and support missions, in distant parts of Europe, for the propagation of the gospel; and, of course, when churches were planted in any country by means of missions and expence, they were always counted dependent on that as the mother church by whom the missionaries were employed. Another excellent piece of policy, by which the church of Rome extended and secured its authority, was the legatine power; introduced by Damascus near the end of the 4th century. The general ambition of the clerical order served also to promote the self-aggrandizing schemes of Rome. The monarchical form of the church, supported by the prejudices and superstition of the people, was the only adequate means both of preserving and of extending the high privileges, honours, titles, and immunities claimed universally by the sacred order, and for which they strenuously contended. This could not fail to induce them to put themselves under the protection of the only bishop in the west, who was both able and willing to support their bold pretensions. The ambition of secular princes also concurred in the establishment and exaltation of the papal hierarchy. The bishop of Rome by his extensive influence had it in his power to excite and foment, or to compromise and terminate internal discord, or foreign contests in all the states, which acknowledged his authority. We must not omit to mention another great engine of papal policy, by which its authority and interest were upheld and promoted, and that is the exemption granted by the pontiffs to particular ecclesiastics or communities, by which their subjection to the ordinary was dispensed with, and their immediate dependance on Rome preserved. From the various circumstances that have been recited, and many others of a similar nature, which our limits constrain us to omit, the rise, establishment,

establishment, extensive influence, and long duration of the church of Rome may be accounted for without difficulty. Moreover, it is easy to perceive that, when Rome had every thing at her disposal, all canons, in regard to discipline, and all decrees, in relation to doctrine, would point invariably to the support of this power. Hence, sprung the convenient doctrines of transubstantiation, purgatory, prayers, and masses for the dead, auricular confession, and the virtue of sacerdotal absolution. Hence also were derived, and, with this view, were enforced the canons extending so immensely the forbidden degrees of marriage, the peculiar power in the popes of dispensing with these, and other canons; the power of canonization, the celibacy of the clergy, the supererogatory merits of the saints, indulgences, and many others. See the several articles, and POPERY.

For the support of such an immense fabric as that of the Romish church, very ample revenues were necessary; and its sources of supply were as various and extensive as the different modifications of its influence and dominion. Every country in which it prevailed, contributed, in a variety of ways, not only to its subsistence, but to its magnificence and to all the costly undertakings in which it engaged. Princes and kingdoms were its tributaries; by impositions and by benevolences; by donations and bequests, it filled its treasures, and amassed wealth sufficient to answer all the purposes of its numberless establishments. It would be endless to recount the various claims which it set up under the names of annats, tythes, peter-pence, reservations, resignations, expectations, graces, &c. besides the casualties arising from pilgrimages, jubilees, indulgences, the dues of appeals, confirmations, dispensations, investitures, &c. &c. which were so many sorts of tribute.

After this brief sketch of the principal circumstances that contributed to the rise and establishment of the church of Rome, or Romish hierarchy, we shall terminate this article, with a concise account of the causes that brought about the declension of this wonderful empire over the consciences, the persons, and the property of mankind. The opinions, we may observe, which are the great bulwarks of spiritual tyranny, are founded in ignorance and superstition; and these are always accompanied with great credulity. We may add, that the three great engines which Rome has employed for maintaining the ignorance of her votaries, and for preventing every acquisition in knowledge that might prove subversive of her high pretensions, are the concealment of Scripture from the people, and even of the import of the forms of public worship, by the daily use of a dead language; the prohibition, under the severest penalties, of every thing which might serve to enlighten and undeceive the world; and the system of persecution. The first two were chiefly calculated for preventing all intercourse with that most formidable enemy of superstition, knowledge; and the third intended principally for checking its progress wherever it appears to have made any advances. By the noble discovery of the art of printing, knowledge has been diffused; and this has proved more baneful to the cause of superstition and tyranny than any event that has happened since the first promulgation of the gospel. Although knowledge had been gaining ground for some centuries before, its progress was slow; but the art of printing served to accelerate its progress to an inconceivable degree. When learning was thus brought within the reach of the middle ranks, the dead languages became a very general study. The Scriptures were read by most students in the Latin vulgate, and by some few in the Greek. The early writers of the church were also read: reading occasioned reflection, and comparison. To this purpose, it is said, that a picture which Huss, one of the first reformers, had procured, and exhibited to the people, in which the entry of our Lord into Jerusalem, riding on an ass, attended by his disciples on foot, in a very homely garb, was contrasted by a procession of the pope and cardinals, in their pontifical habits, and magnificently mounted on the finest horses, richly caparisoned, and adorned with gold, and silver, and jewels, did not a little contribute to excite the indignation of spectators against their spiritual lords, as bearing no resemblance to those meek, humble, and unassuming men, from whom they pretended to derive all their high powers and prerogatives. But the disparity was not less remarkable in disposition and character than in external circumstances. The dignified clergy of the Romish church, as they were both wealthy and powerful, were generally indolent, proud, ambitious, envious, vindictive, and sometimes profligate. Those again, on whom the burden of the service was devolved, as they were both needy and dependent, and often ignorant, had a share of the vices, which commonly accompany these circumstances. They were false, mercenary, and servile. This general charge admits, however, of various exceptions; for in the higher and lower ranks of clergymen, there were many persons whose characters were irreproachable, and lives exemplary. It will also be admitted, as a circumstance of additional importance, that the different kingdoms and states of Europe had, at length, attained a better and more settled constitution than formerly; statesmen began to entertain more extensive views of policy, and princes to understand better their own rights and interests. As men's eyes were opened, they saw more clearly the encroachments and usurpations of the Romish priesthood. This discovery, concurring with the abhorrence and contempt they entertained of many of the priests themselves on personal accounts, namely, the neglect or prostitution of their sacred functions, and the dissoluteness of their lives, led them to inquire a little into the foundations of the high powers and privileges which they claimed. This was a subject which would not bear examination. As the great foundations of the papal hierarchy were the people's ignorance, superstition, and credulity; when these were removed, the whole fabric began to totter and gradually fell to pieces. Accordingly, in all the heresies which sprang up in the different parts of Europe, since the revival of letters, church power seems to have been the principal object at which the reputed heretics aimed. This will appear manifest to any one who considers the accusations brought against Waldo of Lyons, and his followers, Wickliff of England, Huss of Bohemia, Luther of Germany, and Zuinglius of Switzerland; and compares them with those brought against the heresiarchs of the primitive ages, such as Arius, Pelagius, Nestorius, Eutychius, in none of whom was there any direct attack against ecclesiastics. The usurpation and tyranny of ecclesiastical superiors, and the ignorance in which they kept the people, were at first almost the only topics. Hence, they proceeded to censure practical abuses in ceremonies and discipline. The third and last step of their progress was to expose errors in doctrine. For some centuries before the time of Luther, the corruptions that had found their way into the church had been the subject of complaint and murmur in various places. From the time of Wickliff, preaching in England and publishing his sentiments to the world in Latin tracts, which was near a century and a half before the reformation, men's attention was roused to such topics, and people grew bolder every day in speaking out their opinions. In the remote kingdom of Bohemia, Wickliff's doctrine extended its influence, and the fate of his two famous disciples, John Huss and Jerome of Prague, afforded melancholy instances of of it. In what related to the corruptions of the church and of the clergy, together with the exorbitance and abufe of ecclefiaftical power; they were evidently the followers of Wickliff, however they might have differed from him in other particulars; and at length emboldened by his writings and example, they bore an open teftimony to the truth in their native country, and fealed it with their blood at Conftance. This happened about a century before the public remonftrances of Luther, and paved the way for the reformation. Thus previoufly difpofed, as Europe feemed to be, towards the clofe of the 15th and beginning of the 16th century, nothing could be more evident to any perfons of difcernment, than that Chriftendom was ripe for a revolution in its ecclefiaftical polity, and feemed only to wait for a favourable occafion. Such an occafion the avarice of pope Leo X., and the impiety, as well as indifcretion, of his minifters and agents, foon furnifhed. Campbell's Ecclef. Hift. paffim. See *Lutheran* CHURCH, *Reformed* CHURCH, LUTHER, and REFORMATION.

CHURCH, *Gallican*, denotes the church of France, as it fubfifted before the revolution, under the direction and government of its bifhops and paftors. This church has always enjoyed certain immunities and franchifes, not as grants from the popes, but derived to her from her firft original, which fhe has carefully maintained. Thefe privileges depend on two maxims; viz. 1. That the pope has no authority or right to command or order any thing, general or particular, in which the temporalities and civil rights of this kingdom are concerned. 2. That notwithftanding the pope's fupremacy is owned in cafes purely fpiritual, yet in France, his power is limited and regulated by the decrees and canons of ancient councils, received in that realm. A fcheme of union between the church of England and the Gallican church was projected by the doctors of the Sorbonne in the beginning of the 18th century; and a correfpondence was carried on, in 1717 and 1718, between archbifhop Wake and Dr. Du Pin on the fubject; which terminated without fuccefs.

CHURCH, *Reformed*, in a general fenfe, comprehends all thofe churches that have feparated from the church of Rome, and that have renounced the fpiritual jurifdiction and fupremacy of the Roman pontiff. Accordingly, the Romanifts call it the "Weftern Schifm," as they denominate the Greek church the "Eaftern Schifm."

The denomination of "reformed" is often reftricted to thofe Proteftant churches which did not embrace the doctrine and difcipline of Luther. The title was firft affumed by the French Proteftants, and afterwards became the common denomination of all the Calviniftical churches on the continent. But in England the term "reformed" is generally ufed in its genuine and extenfive fenfe, as ftanding in oppofition to popery alone; and in this large fenfe it comprehends the Lutheran church in all its modifications, the Calvinift church, the church of England, the church of Scotland, &c. When this epithet of "reformed" is ufed in oppofition to the community founded by Luther, it reprefents not a fingle church, as the epifcopal, Prefbyterian, or Independent, but rather a collection of churches; which, though they be invifibly united by a belief and profeffion of the fundamental doctrines of Chriftianity, yet frequent feparate places of worfhip, and have, each of them, a vifible centre of external union peculiar to themfelves, which is formed by certain peculiarities in their refpective rules of public worfhip and ecclefiaftical government. This matter may be illuftrated by an attentive examination of the difcipline, polity, and worfhip of the churches of England, Scotland, Holland, and Switzerland. The firft of thefe churches, being governed by bifhops, and not admitting the validity of the Prefbyterian ordination, differs from the other three more than any of thefe differ from each other. There are, however, peculiarities of government and worfhip, that diftinguifh the church of Holland from that of Scotland. The inftitution of deacons, the ufe of forms for the celebration of the facrament, an ordinary form of prayer, the obfervation of the feftivals of Chriftmas, Eafter, Afcenfion-day, and Whitfuntide are eftablifhed in the Dutch church; and, it is well known, that the church of Scotland differs from it extremely in thefe refpects. For an account of the origin, progrefs, and eftablifhment of the "reformed church," in the more general fenfe of the term; fee REFORMATION.

The founder of the "reformed church," in a more reftricted fenfe, was Ulrick Zuingle, a native of Switzerland, who combined, with uncommon penetration and acutenefs, an ardent zeal for truth. Zuingle wifhed to remove out of the churches, and to abolifh in the ceremonies and appendages of public worfhip, many things which Luther was difpofed to treat with toleration and indulgence; fuch as images, altars, wax-tapers, the form of exorcifm, and private confeffion. What he aimed at eftablifhing in his country was a method and form of divine worfhip diftinguifhed by its fimplicity, and as far remote as could be from every thing that might have the fmalleft tendency, according to his ideas, to nourifh a fpirit of fuperftition. Moreover, his fentiments concerning feveral points of theology, and more efpecially his opinions relating to the facrament of the Lord's Supper, were very different from thofe of Luther. Of thefe fentiments and opinions feveral were adopted in Switzerland by thofe who concurred with Zuingle in promoting the caufe of the reformation, and were tranfmitted by them to all the Helvetic churches that threw off the yoke of Rome. From Switzerland thefe opinions were propagated among the neighbouring nations by the friends and difciples of Zuingle; and thus the primitive reformed church, that was founded by this eminent ecclefiaftic, and whofe extent at firft was not very confiderable, gathered ftrength by degrees, and made daily new acquifitions. After the death of Zuingle, feveral Lutheran doctors of the more moderate fort, and particularly Martin Bucer, made an attempt to form a kind of reconciliation between the partizans of the Lutheran and reformed churches; but their endeavours were unfuccefsful. The breach between them was widened by Calvin, who, by his activity and zeal, confiderably enlarged the boundaries of the reformed church, propagated his doctrine, and gained profelytes and patrons to his theological fyftem, in feveral countries of Europe. The plan of doctrine and difcipline, which Zuingle had formed, was altered and corrected by Calvin, particularly in relation to three points. Zuingle, in his form of ecclefiaftical government, had given an abfolute and unbounded power, in religious matters, to the civil magiftrate, to whom he had placed the clergy in a degree of fubjection, with which many were offended. He allowed, however, certain fubordination and difference of rank among the minifters of the church, and thought it expedient to place at their head a perpetual prefident, or fuperintendant, with a certain degree of infpection and authority over the whole body. Calvin, on the contrary, reduced the power of the magiftrate, in religious matters, within narrow bounds. He declared the church a feparate and independent body, endowed with the power of legiflating for itfelf. He maintained that it was to be governed by two ecclefiaftical bodies, viz. "the venerable company" of the paftors and profeffors, and the "confiftory;" and he left to the civil magiftrate little elfe befides the privilege of protecting and defending the church, and providing for what related to its external exigencies and concerns. Thus this eminent reformer introduced into the republic of Geneva, and endeavoured to introduce into all the reformed churches throughout Europe, that form of ecclesiastical government, which is called "Presbyterian," from its neither admitting the institution of bishops, nor any subordination among the clergy; and conformably to this principle, that all ministers of the Gospel are, by the law of God, declared to be equal in rank and authority. In consequence of this principle, he established at Geneva a consistory, or ecclesiastical judicatory, over which he himself presided (though at his death he advised the clergy not to give him a successor), composed of ruling elders, partly pastors and partly laymen; and he invested this ecclesiastical body with a high degree of power and authority. He also convened synods, composed of the ruling elders of different churches, and in these consistories and synods had laws enacted for the regulation of all matters of a religious nature, and among other things restored to its former vigour the ancient practice of excommunication. All these things were done with the consent of the greatest part of the senate of Geneva. Calvin also, with a view, as it is said, of facilitating the desired union with the Lutheran church, substituted, instead of the system adopted by Zuingle with regard to the eucharist, another, which appeared more conformable to the doctrine of that church, and which, in reality, differed little from it. The doctrine of Zuingle supposed only a symbolical, or figurative, presence of the body and blood of Christ in the eucharist, and represented a pious remembrance of Christ's death, and of the benefits it procured to mankind, as the only fruits that arose from the celebration of the Lord's Supper; whereas Calvin acknowledged a real, though spiritual, presence of Christ in this sacrament; or, in other words, he maintained, that true Christians were, by this ordinance, in a certain manner united to the man Christ; and that from this union the spiritual life derived true vigour in the soul, and was still carried on, in a progressive motion, to greater degrees of purity and perfection. See CONSUBSTANTIATION, EUCHARIST, and IMPANATION. Moreover, Calvin zealously inculcated the absolute decree of God, with respect to the future and everlasting condition of the human race, which formed no part of the theological creed of Zuingle. The first of the above-mentioned points was not universally allowed, notwithstanding the credit and influence of Calvin, in the reformed churches. The English and Germans rejected it, and even the Swiss refused to adopt it. It was, however, received by the reformed churches in France, Holland, and Scotland. Several churches, more especially those of Zurich and Bern, obstinately maintained the doctrine of Zuingle in relation to the eucharist; neither could they be easily persuaded to admit, as an article of faith, the doctrine of predestination, as it had been taught by Calvin. His followers, nevertheless, in process of time, aided by his high reputation and learned writings, induced almost all the reformed churches to adopt his theological system. In various provinces of Germany, the tenets, rites, and institutions of the church of Geneva, were adopted and enforced by the ruling powers. This was the case, particularly, with the palatinate and the republic of Bremen. The French Protestants, very generally, entered into the bonds of fraternal communion with the church of Geneva. See CHURCH of *Scotland* and CHURCH of *England*.

CHURCH, *Lutheran*, derives its appellation from Luther, who, having been eminently instrumental in bringing about the reformation (which see), formed the project of founding a church upon principles entirely opposite to those of Rome, and of establishing in it a system of doctrine and ecclesiastical discipline, which he conceived to be agreeable to the spirit and precepts of the Gospel. Accordingly, the rise of this church must be dated from that remarkable period, when the pontiff Leo X. drove Martin Luther, with his friends and followers, from the bosom of the Roman hierarchy, by a solemn and violent sentence of excommunication; and it began to acquire a regular form, and a considerable degree of stability and consistence, from the year 1530, when the system of doctrine and morality it had adopted was drawn up and presented to the diet of Augsburg. It was raised to the dignity of a lawful and complete hierarchy, totally independent on the laws and jurisdiction of the Roman pontiff, in consequence of the treaty concluded at Passau in the year 1552, between Charles V. and Maurice, elector of Saxony, relating to the religious affairs of the empire. The great and leading principle of the Lutheran church, says Mosheim (Eccl. Hist. vol. iv.) is, that the Holy Scriptures are the only source from whence we are to draw our religious sentiments, whether they relate to faith or practice; and that these inspired writings are, in all matters essential to salvation, so plain, and so easy to be thoroughly understood, that their signification may be learned, without the aid of an expositor, by every person of common sense, who has a competent knowledge of the language in which they are composed. There are, also, certain formularies adopted by this church, which contain the principal points of its doctrine; but the books, containing these formularies, have no authority beyond what they derive from the scriptures of truth, whose sense and meaning they are designed to convey; nor are the Lutheran doctors permitted to interpret or explain these books so as to draw from thence any propositions that are inconsistent with the express declarations of the word of God. The principal of these human productions is the "Confession of Augsburg," with the annexed "Defence" of it. In the next rank may be placed the "Articles of Smalcald," together with the shorter and larger "Catechisms of Luther." To these standard books most churches add the "Form of Concord." The supreme civil rulers of every Lutheran state are invested with the dignity and perform the functions of supremacy in the church; but they are effectually restrained, by the fundamental pinciples of the doctrine they profess, from any attempt to change or destroy the established rule of faith and manners, to make any alteration in the essential doctrines of their religion, or in any thing that is intimately connected with them, or to impose their particular opinions upon their subjects in an arbitrary and despotic manner.

The councils, or societies, appointed by the sovereign to watch over the interests of the church, and to govern and direct its affairs, are composed of persons versed in the knowledge both of civil and ecclesiastical law, and, according to a very ancient denomination, are called "consistories." The internal government of the Lutheran church seems equally removed from episcopacy on the one hand, and from Presbyterianism on the other, if we except the kingdoms of Sweden and Denmark, in which the church is ruled by bishops and superintendents, under the inspection and authority of the sovereign. The archbishop of Upsal is primate of Sweden, and the only archbishop among the Lutherans; and his revenues do not amount to more than 400l. annually; and those of the other bishops are proportionably small. Every country has its own liturgies which prescribe every thing that relates to external worship and the public exercise of religion. Assemblies for the celebration of divine worship meet every where at stated times. The Holy Scriptures are publicly read, prayers and hymns are addressed to the Deity, the sacraments are administered, and the people are instructed in the knowledge of religion, and excited to the practice of

virtue

virtue by the discourses of their ministers. Among the days that are held sacred in the Lutheran church, besides Sunday, we may reckon all such as were signalized by the glorious and important events that proclaim the celestial mission of the Saviour, and the divine authority of his holy religion. The Lutheran church has extended itself to Asia and America; and formed several congregations in those remote parts of the world. Mosheim's E.H. vol. iv.

CHURCH *of England* is that branch of the reformed church which was established in England after the separation from the Romish church; which took place in the reign of Henry VIII. who renounced the pope's supremacy. The English, who first threw off the yoke of Rome, seemed to be more inclined to the sentiments of Luther concerning the eucharist, the form of public worship, and ecclesiastical government, than to those of the Swiss churches. But after the death of Henry VIII. the scene changed; when, by the industrious zeal of Calvin and his disciples, more especially Peter Martyr, the cause of Lutheranism lost ground considerably; and the universities, schools, and churches, became the oracles of Calvinism, which also acquired new votaries among the people. Accordingly, when it was proposed, in the reign of Edward VI. to give a fixed and stable form to the doctrine and discipline of the church, Geneva was acknowledged as a sister church; and the theological system, then established by Calvin, was adopted, and rendered the public rule of faith in England. This, however, was done without any change of the episcopal form of government which had always taken place, and was entirely different from that of Geneva; and several religious rites and ceremonies were retained, which many of the reformed considered as superstitious. This latter circumstance gave rise to many dissensions in subsequent ages, which proved detrimental both to the civil and ecclesiastical constitution of Great Britain. The controversy concerning the ceremonial part of divine worship, commenced with those exiles who, in 1554, fled from the bloody rage and inhuman tyranny of queen Mary, and took refuge in Germany. After the accession of queen Elizabeth, these exiles returned to their own country, and renewed the contest at home which had begun abroad. Queen Elizabeth, unwilling to strip religion of the ceremonies which remained in it, was rather inclined to bring the public worship still nearer the Romish ritual; and had a great propensity to several usages in the church of Rome, which were justly looked upon as superstitious. She publicly thanked one of her chaplains, who had preached in defence of the real presence; she was fond of images, and retained some in her private chapel, and would undoubtedly have forbidden the marriage of the clergy, if Cecil, her secretary, had not interposed. Having appointed a committee of divines to review king Edward's liturgy, she gave them an order to strike out all offensive passages against the pope, and to make people easy about the corporal presence of Christ in the sacrament. For an account of the disputes that agitated the country on this occasion, see the article PURITAN.

From the time of Henry VIII. the kings of England have considered themselves as supreme heads of the church, in relation both to its spiritual and its temporal concerns; and on the ground of this title, both Henry VIII. and his son Edward assumed an extensive authority and jurisdiction in the church, and seemed to consider their spiritual power as equal to that which had been unworthily possessed and exercised by the Roman pontiff. Accordingly the constitution of the church of England resembled that of the state, and a striking analogy subsists between the civil and ecclesiastical governments established in this country. The clergy, consisting of the upper and lower houses of convocation, are assembled (whenever they do assemble) by the archbishop of Canterbury, in consequence of an order from the sovereign, and in these meetings are proposed, in common council, such measures as seem to be necessary to the well-being of the church: these measures are laid before the king and parliament, and derive from their approbation and authority the form of laws.

The 37th article of the church of England expressly declares and ordains that "the queen's majesty hath the chief power in this realm of England, and other her dominions, unto whom the chief government of all estates of this realm, whether they be ecclesiastical or civil, in all causes, doth appertain, and is not, nor ought to be, subject to any foreign jurisdiction." It is well known, however, that for the first three centuries, the Christian religion was not embraced or protected by any Roman emperor. But after the conversion of Constantine, this first Christian emperor, and many of his successors, enacted laws which are now extant in the codes of Theodosius and Justinian, relative to ecclesiastical matters. When the empire of Rome was divided into independent kingdoms, the sovereigns exercised the same authority over all their subjects, without any distinction, and made such regulations, free from all foreign controul, as appeared to them expedient for the good government of their respective churches. This continued to be the case till the aspiring ambition of the bishops of Rome prompted them to claim universal dominion, not only over ecclesiastics, but over sovereign princes, throughout the Christian world. Of the fact there is no question; and it has been alleged by the advocates of the supremacy of the sovereign, that the authority which the constitution of Great Britain gives to our sovereign in ecclesiastical affairs, is founded in Scripture; is conformable to the practice of the times previous to the corruptions and usurpations of popery; and is perfectly agreeable to the reason and nature of things. This claim, however, was contested, on the grounds both of reason and Scripture, soon after it was assumed; and it has been considered by many persons in later times as inconsistent with the evangelical constitution of the Christian church, and with the sole legislative, judicial, and sovereign authority of Christ, the head of the church, in all religious matters. It has been also maintained, that the subjection to higher powers, and obedience to magistrates, which the Scripture enjoins on Christians, relate only to civil, but not at all to religious matters; for this obvious reason, that the magistracy at that time was every where Pagan. See SUPREMACY.

Moreover, the 20th article of the church of England declares and ordains, "that the church hath power to decree rites and ceremonies, and authority in controversies of faith; and yet it is not lawful for the church to ordain any thing that is contrary to God's word written, neither may it so expound one place of Scripture, that it be repugnant to another." This article, from the time of its first introduction to the present day, has been the occasion of great difference of opinion and of dispute between its defenders on the one hand, and its opposers on the other. By the former it has been argued, that, the church being a society of men united for the most important purposes, it is necessary that its affairs, like those of every other society, should be conducted by certain rules; and that, although the New Testament does not contain any particular directions upon the subject of rites and ceremonies, every church is left at liberty to prescribe such to its own members as are consistent with the general precepts enjoined by the sacred writers; such as "Give none offence;" "Let all things be done decently and in order;" "Let all things be done unto edifying, &c."

This

This liberty, it is said, was allowed under the Jewish dispensation; and hence it is concluded that it is lawful for a society of Christians, whose religion is designed for all ages and countries, to make any regulations which may tend to promote the great objects for which they have formed themselves into one body. In vindication of the authority ascribed to the church in controversies of faith, reference has been made to the decree of the apostles and elders assembled at Jerusalem, which was communicated to the churches then established in different parts of Asia, and to which their obedience was required; and it has been said, that this was an instance of authority exercised by the church, under the direction of the inspired apostles, in a controversy of faith. Two passages have also been cited (viz. 1 Tim. i. 3, and Titus iii. 10.) in order to shew, that Timothy and Titus had authority given them to regulate the faith of the churches over which they were appointed to preside; and hence it has been inferred, that there must have been, at that very early period, some fixed test, by which the faith of professed Christians was to be judged: the consequence of not conforming to which test was, by apostolical authority, excommunication. It is further added, that this practice appears, from ecclesiastical history, to have been usual in every period of the Christian church. See the lord bishop of Lincoln's Elements of Christian Theology, vol. ii. On the other hand, it has been pleaded, that this authority claimed by the church of England is lodged in the king and parliament of these realms, and not with the church, considered as composed of the bishops and clergy. It has been said, that all the clergy of this kingdom, with all the bishops at their head, have not the least authority to enjoin one ceremony or rite of worship; or to either establish or annul one article of faith. All power and jurisdiction pertaining to these matters is lodged chiefly in lay-hands; it is solely in the king and parliament, under whose direction and controul the clergy are to act. It has been also said, that the bishops and clergy were so far from having any hand in the first forming of our present established church, or in ordering its rites and articles of faith; that it was done not only without, but in actual opposition to them: for in the 1st of queen Elizabeth the parliament alone established the queen's supremacy and the common-prayer book, in spite of all opposition from the bishops in the House of Lords; and the convocation then sitting was so far from having any hand in those church acts for reformation, that it presented to the parliament several propositions in behalf of the tenets of popery, directly contrary to the proceedings of the parliament. It has been also queried, who gave the civil magistrate this power to decree rites in Christian worship, which Christ never decreed, and to make articles of faith which Christ never made? See Mr. White's Three Letters, and the Dissenting Gentleman's Answer.

It was the general opinion of the British divines that lived in the earliest period of the Reformation, and though it was first abandoned by archbishop Whitgift, it has been maintained by later writers of the highest rank in the church, (see Elem. of Theology, above cited,) "that Jesus Christ has left upon record no express injunctions with respect to the external form of government that is to be observed in his church; and, consequently, that every nation hath a right to establish such a form, as seemeth conducive to the interests, and to the peculiar state, circumstances, and exigencies of the community, provided that such an establishment be in no respect prejudicial to truth, or favourable to the revival of superstition." See Bishop.

The doctrines of the church of England are contained in the 39 articles. (See Article *of Faith*.) These articles were principally compiled by archbishop Cranmer; and it appears, from some passages quoted by the bishop of Lincoln, (*ubi supra*,) from a publication, entitled, "Necessary Doctrine and Erudition for any Christian Man," which was confirmed by act of parliament, that his sentiments on the subject of predestination and grace inclined more to those afterwards inculcated by Arminius and the synod of Dort, than to those of Calvin; and in this respect the sentiments of Ridley, Latimer, and Hooper, coincided with those of Cranmer. The worship of the church of England was directed by a liturgy, for an account of which, see Liturgy. When James I. ascended the throne on the death of Elizabeth, the Puritans entertained hopes, from his having received his education in Scotland, that he would mitigate the vexations they had suffered from their attachment to the discipline and worship of the church of Geneva. But they soon found that their expectations were unfounded. An episcopal hierarchy was more favourable to his views than the Presbyterian form of ecclesiastical government; and he, therefore, distinguished the bishops with peculiar expressions of his favour, extended their authority, increased their prerogatives, and publicly adopted and inculcated the following maxim, "No bishop, no king." When the British divines returned from the synod at Dort, the king, together with the greatest part of the episcopal clergy, discovered their inclination to the sentiments of Arminius, relating to the divine decrees, which they thought preferable to those of Calvin and Gomarus. His son and successor, Charles I., who had imbibed his father's political and religious principles, directed the whole scope of his administration towards the three following objects: "The extending of the royal prerogative, and the raising of the power of the crown above the authority of the law—the reduction of all the churches of Great Britain and Ireland under the jurisdiction of bishops, whose government he looked upon as of divine institution, and also as the most adapted to guard the privileges and majesty of the throne—and, lastly, the suppression of the opinions and institutions that were peculiar to Calvinism, and the modelling of the doctrine, discipline, ceremonies, and policy of the church of England, after the spirit and constitution of the primitive church." The instrument he employed for the execution of his plan was bishop Laud of London, afterwards archbishop of Canterbury. (See the article Laud.) After the death of Laud, when the dissensions between the king and parliament arrived at their height, the great council of the nation, instigated by the Puritans and Independents, abolished episcopal government; and proceeded to condemn and abrogate every thing in the ecclesiastical establishment that was contrary to the doctrine, worship, and discipline of the church of Geneva. As soon as Charles II. was re-established on the throne of his ancestors, the ancient forms of ecclesiastical government and public worship were restored; and in 1662, a public law, intitled, the "Act of Uniformity," was enacted, by which all who refused to observe the rites, and subscribe the doctrines, of the church of England, were entirely excluded from its dominion. In the reign of king William, and particularly in 1689, the divisions among the friends of episcopacy ran high, and terminated in that famous schism, if it may be so called, in the church of England, which produced the two parties denominated "High Church," or "Non-Jurors," and "Low-Churchmen."

The Church of England which is now the chief and leading branch of the great community distinguished by the denomination of the Reformed Church, continues much in the same state and is governed by the same principles, which it assumed at the revolution, under the reign of king William

liam III. The established form of church-government is episcopacy, which is embraced by the sovereign, the nobility, and the greatest part of the people. The Presbyterians and other numerous sects comprehended under the general appellation of non-conformists, enjoy the sweets of religious liberty, under the influence of a legal toleration; and whatever may be the private sentiments or governing dispositions of a few individuals, the dignitaries of the church and the rulers of the state manifest a liberal and candid temper; nor is there any reason to apprehend any species or degree of persecution, in the present enlightened age, either from the church or the state. Those who are comprehended within the pale of the church, and those who are without it, enjoy, as far as the civil or ecclesiastical government is concerned, unmolested freedom and tranquillity. The members of this church may be divided into two classes, according to their different ideas of the origin, extent, and dignity of episcopal jurisdiction. Whilst some look upon the government of bishops to be founded on the authority of a divine institution, and are zealous for extending the power and prerogatives of the church, of which description, the number, we conceive, is very inconsiderable; others, and they form the very decided majority, of a more mild and sedate spirit, though they consider the episcopal form of government as far superior to every other system of ecclesiastical polity, and recommend all the precautions that are necessary for its preservation and the independence of the clergy, yet do not carry this attachment to such an excessive degree, as to refuse the name of a "church" to every religious community that is not governed by a bishop, or to defend the prerogatives and pretensions of the episcopal order with an intemperate zeal. To the spirit of the established church of England, in relation to those who dissent from its rule of doctrine and government, we have already paid our tribute of respect and commendation. We shall close this part of our article with the words of the learned and amiable Dr. Jortin, (Diss. ii. p. 3.) as they are cited by the bishop of Lincoln *(ubi supra)*, without taking upon us to determine whether the articles of the church are Calvinistic or Arminian, or what is the proportion of those who adopt either scheme of interpreting them, or vouching for the justice of the representation: "In England, at the time of the synod of Dort, we were much divided in our opinion concerning the controverted articles; but our divines having taken the liberty to think and judge for themselves, and the civil government not interposing, it has come to pass, that from that time to this, almost all persons here, of any note for learning and abilities, have bid adieu to Calvinism, have sided with the Remonstrants, and have left the Fatalists to follow their own opinions, and to rejoice (since they can rejoice) in a religious system consisting of human creatures without liberty, doctrines without sense, faith without reason, and a God without mercy."

The revenue of the church of England has been stated by two late writers, from whose publications we shall extract the following particulars. The bishop of Landaff (Dr. Watson) in his "Letter to the Archbishop of Canterbury," printed in 1783, assures us, that the whole income of the church, including bishoprics, deans and chapters, rectories, vicarages, dignities, and benefices of all kinds, and even the two universities with their respective colleges, doth not amount, upon the most liberal calculation, to 1,500,000 *l.* a year. Consequently, if we had no bishops to inspect and govern the church; no deaneries, prebendaries, or canonries, to stimulate the clergy to excel in literary attainments; no universities or colleges to instruct our youth; nothing but parochial clergy, and all of these provided for by an equal partition of the present ecclesiastical revenues, there would not be, estimating the number of the clergy at ten thousand, above 150 *l.* a year for each individual. The learned prelate adds, that though the whole revenue of the church is so inconsiderable, as not to admit any diminution of it, yet a somewhat better distribution of it might be introduced, with much advantage to the state, and without the least injustice to any individual. For an account of the plan which he proposes, see AUGMENTATION. Another writer, Mr. Cove, vicar of Sithney in Cornwall, in his "Essay on the Revenues of the Church of England," 2d ed. 1797, says, that though the cathedral revenues, throughout the kingdom, amount to the gross sum of 140,000 *l.* *per annum*, there are in all, not less than 1700 persons who, in a greater or smaller proportion, participate these revenues. The parochial clergy, he adds, have been more fortunate and successful than either their episcopal or dignified brethren. Their incomes, being chiefly dependent on the state of landed property, whosoever might be the possessors of it, have been necessarily more augmented by the increased value of the rental of that property; and their rights and claims, not being of a fleeting nature, but immoveably affixed to the soil of each parish, have suffered little diminution, except from the easiness, inattention, and neglect of the clergy themselves.

It appears from the "Liber Regis," according to archdeacon Plymley in his "Charge to the Clergy of Salop, in the year 1793," that there are in England and Wales 5,098 rectories, 3,687 vicarages, and 2,970 churches, which are neither rectorial nor vicarial; in all 11,755 churches, contained in about 10,000 parishes, at which number the parishes throughout the kingdom are usually estimated.

Of these rectories many are, without doubt, highly valuable. The same may be said in respect to some of the vicarages, from being possessed of large glebes or large endowments, or from both causes united; but however there are many rectories, and vicarages, in particular, whose tithes are wholly impropriated, and without even any parsonage house. Of the churches, which are neither rectorial nor vicarial, perhaps two-fifths are merely chapels of ease, and appendant to some extensive and valuable benefices, or else built on speculation in populous parts of the kingdom, in which districts they are chiefly to be found. And of the remaining churches to which neither houses, glebes, nor tithes most commonly belong, the incomes must necessarily be very inconsiderable, as they can alone proceed from trifling contingencies.

From the aggregate amount of the incomes of 3,181 livings, now and formerly in charge in the king's books, situated in every county in the kingdom, and whose value hath been collected almost entirely within the last ten years, from various sources of public and private information, it appears that each of these livings is now worth, on the average, 141 *l.* per annum, and that when compared with the value annexed to them in the king's books, they have all increased in the general proportion of about ten to one, since the time of the reformation; but that the rectories have increased in the ratio of nearly eleven to one, and are at present of the yearly value of 162 *l.* each, and that the vicarages have increased in the ratio of rather more than nine to one, and are at present of the yearly value of 106 *l.* each. The number of rectories included in this calculation, is 2,037, and of the vicarages 1,144; the collective value of the former in the king's books being 30,158 *l.* and of the latter 13,379 *l.*, and the collective value of the former at present being 330,754 *l.* and of the latter 121,403 *l.* per annum.

 According,

According, then, to the prefent average value of thefe rectories and vicarages, and to the number of the rectorial, vicarial, and other churches throughout the kingdom, as before given from the "Liber Regis," the revenues of the parochial clergy will be increafed to the amount of 1,313,000 *l.* per annum, as thus appears: 5,098 rectories, at 162 *l.* each, will give 825,876 *l.*—3,687 vicarages, at 106 *l.* each, will give 398,222 *l.* And 1782 (that is, three-fifths of 2,970) churches, which are neither rectorial nor vicarial, but are prefumed to be parochial cures, at, fuppofe the ample allowance of—50 *l.* each, will give 89,100 *l.* And, when to thefe fums are added the epifcopal, cathedral, and univerfity revenues amounting, to 392,000 *l.* per annum, it will be feen that the bifhop of Landaff's valuation of the church and univerfity revenues is exceeded by the fum of 205,000 *l.*

From the revenues, this author proceeds to form an eftimate of the number of the eftablifhed clergy:

They have been varioufly eftimated, as much above 20,000 as below 15,000; a medium between both, or 18,000, is, moft probably, the correcteft ftatement of them, as it will allow a fupernumerary or curate to about one half of the before ftated number of 11,755 churches.

Thefe eighteen thoufand perfons, whether beneficed or expectant, with their families and dependents, make up poffibly near 100,000 fouls, reckoning at the rate of five and an half perfons to a family. However, as a part of the clergy, like thofe of other profeffions, may be fuppofed to be fingle men, this computation will therefore at firft fight appear exaggerated; but, when it is confidered that the clergy are an exception to thofe of other profeffions, and are for the moft part married men with numerous families in general, the calculation, in eftimating the whole body of them with each a family of five and an half perfons, may turn out neither rafh nor ill-founded; and more efpecially, fince computing two-thirds of them to be married men, with families and dependents of feven perfons each, the fame grofs product will almoft appear, as feven times twelve thoufand amount to 84,000, and the remaining one-third, (or 6,000 fingle men) with one dependent each, will make up the whole number to be 96,000.

And thus, taking the population of the kingdom at 8,000,000 of perfons, the clergy, with their families and dependents, are about an eightieth part of the people.

It appears that, by the addition of the cathedral and the equalization of the parochial incomes, the revenue to be enjoyed by each parifh prieft would not exceed 172 *l.* per annum.

Church *of Scotland*, is that branch of the reformed church which was eftablifhed in Scotland. One of the principal agents in accelerating and completing the progrefs of the reformation in Scotland was John Knox, who, with better qualifications of learning, and more extenfive views than any of his predeceffors in Scotland, poffeffed a natural intrepidity of mind, which fet him above fear. He began his public miniftry at St. Andrew's, in the year 1547, with that fuccefs which always accompanies a bold and popular eloquence. Inftead of amufing himfelf with lopping the branches, he ftruck directly at the root of popery, and attacked both the doctrine and difcipline of the eftablifhed church, with a vehemence peculiar to himfelf, but admirably fuited to the temper and wifhes of the age. The great revolution in England, which followed upon the death of Henry VIII. contributed no lefs than the zeal of Knox towards demolifhing the popifh church in Scotland. Several noblemen of the greateft diftinction having about this time openly efpoufed the principles of the reformer, they were no longer under the neceffity of inculcating their fentiments with the referve which they had before practifed; and with greater fecurity and encouragement, they had likewife greater fuccefs. The ambition of the houfe of Guife and the bigotry of Mary of England haftened the fubverfion of the papal throne in Scotland; and by a fingular difpofition of Providence, the perfons who oppofed the reformation in every other part of Europe with the fierceft zeal, were made inftruments for advancing it in that kingdom. It was not, however, till about the year 1560 that the Proteftant church of Scotland began to affume a regular form. But the model introduced by the reformers differed extremely from that, which had been fo long eftablifhed. As the vices of the clergy had, at firft, fays Dr. Robertfon (Hift. of Scotland), excited the indignation of mankind, and roufed that fpirit of inquiry, which proved fo fatal to the whole popifh fyftem; as this difguft at the vices of ecclefiaftics was foon transferred to their perfons, and fhifting from them, by no violent tranfition, fettled at laft on the offices which they enjoyed; the effects of the reformation would naturally have extended not only to the doctrine, but to the government of the popifh church; and the fame fpirit which abolifhed the former would have abolifhed the latter. But, in a great part of Germany, in England, and in the northern kingdoms, its operations were checked by the power and policy of their princes; and the ancient epifcopal jurifdiction, under a few limitations, was ftill continued in thofe churches. The epifcopal hierarchy appears to be more conformable to the practice of the church, fince Chriftianity became the eftablifhed religion of the Roman empire. The ecclefiaftical government was, at that time, plainly copied from the civil; the firft not only borrowed its form, but derived its authority from the latter; and the diocefes and jurifdictions of patriarchs, archbifhops, and bifhops, correfponded with the divifion and conftitution of the empire. In Switzerland, and the Low Countries, the nature of the government allowing full fcope to the genius of the reformation, all pre-eminence of order in the church was deftroyed, and an equality eftablifhed more fuitable to the fpirit of republican policy. The fituation of the primitive church fuggefted the idea, and furnifhed the model of the latter fyftem, which has fince been called "Prefbyterian." The firft Chriftians, oppreffed by continual perfecutions, and obliged to hold their religious affembles by ftealth, and in corners, were contented with a form of government extremely fimple. The influence of religion concurred with the fenfe of danger in extinguifhing among them the fpirit of ambition, and in preferving a parity of rank, the effect of their fufferings, and the caufe of many of their virtues. Calvin, whofe decifions were received, among the Proteftants of that age, with incredible fubmiffion, was the patron and reftorer of this fcheme of ecclefiaftical policy. The church of Geneva, formed under his eye, and by his direction, was efteemed the moft perfect model of this government; and Knox, who, during his refidence in this city, had ftudied and admired it, warmly recommended it to the imitation of his countrymen. Among the Scottifh nobility, fome hated the perfons, and others coveted the wealth of the dignified clergy; and by abolifhing that order of men, the former indulged their refentment, and the latter hoped to gratify their avarice. The people, inflamed with the moft violent deteftation of popery, and approving every fcheme that departed fartheft from the practice of the Romifh church, were delighted with a fyftem, fo admirably fuited to their predominant paffion. While the friends of civil liberty beheld, with pleafure, the Proteftant clergy pulling down, with their own hands, that fabric of ecclefiaftical power, which their predeceffors had reared with fo much art and induftry; and flattered.

ed themselves, that by lending their aid to strip churchmen of their dignity and wealth, they might entirely deliver the nation from their exorbitant and oppressive jurisdiction. However, on the first introduction of his system, Knox did not deem it expedient to depart altogether from the ancient form. Instead of bishops, he proposed to establish 10 or 12 superintendents in different parts of the kingdom. These, as the name implies, were empowered to inspect the life and doctrine of the other clergy. They presided in the inferior judicatories of the church, and performed several other parts of the episcopal function. Their jurisdiction, however, extended to sacred things only; they claimed no seat in parliament; and pretended to no right to the dignity, or revenues, of the former bishops. The number of inferior clergy, to whom the care of parochial duty could be committed, was still extremely small, and much dispersed through the different provinces of the kingdom; and in a few places only, were they formed into regular classes or societies. The first general assembly of the church was held this year (December 20, 1560.) See *General* ASSEMBLY. In order to give greater strength and consistence to the Presbyterian plan, Knox, assisted by his brethren, composed the first book of discipline, which contains the model or platform of the intended policy. From this period to the present times, the form of doctrine, worship, and discipline, that had been established at Geneva by the ministry of Calvin, and introduced with certain modifications by Knox into Scotland, has been maintained with invincible steadiness and zeal; and every attempt to introduce into that kingdom the rites and government of the church of England, or to re-establish popery, has proved impotent and unsuccessful.

The church of Scotland is, of course, considered by its members as founded upon the principle of the primitive church, in which they perceive no distinction between presbyters and bishops. A body of presbyters having a moderator, who conducts the proceedings, and executes the sentences, is regarded as competent to perform all the acts which, in an episcopal government, belong exclusively to the bishop. It tries the qualifications of candidates for the office of the ministry; it confers orders by the imposition of hands; to those who are nominated by persons having right of nomination, it grants the investiture of the sacred office, or induction into the charge of a particular parish; and it exercises inspection and jurisdiction over the pastors of all the parishes within its bounds.

In the exercise of his spiritual functions a pastor acts within his parish, according to his own discretion: and for the discharge of the pastoral duties, he is accountable only to the presbytery from whom he received the charge of the parish; but in every thing which relates to *discipline*, he is assisted by lay-elders. These, like the deacons of the primitive church, attend to the interests of the poor. But their peculiar business is expressed by the name *ruling-elders;* in every question of jurisdiction within the parish, they form a spiritual court, of which the minister is moderator. In the presbytery also they sit as representatives of sessions or consistories.

Ministers are admitted into a church by a presbytery. When a student has gone through his university education, according to certain prescribed rules, he may be proposed to a presbytery, in order to be taken upon his trials; the consent of a superior court, called a synod, having been first obtained; to which court an appeal lies, if the presbytery should be oppressive. A person entered upon his trials, having obtained a licence to preach, is called a probationer; and in this character has no fixed charge, though he is allowed to assist a clergyman disabled by age or sickness. When he receives a presentation, he undergoes a second trial before the presbytery, to whom the presentation is addressed: if they find that he is not qualified in respect of doctrine, literature, or moral character, their sentence declaring him unqualified, unless it be reversed by their ecclesiastical superiors, renders his presentation void. If, upon a vacancy in the living, the patron do not present within six months, the presbytery take such steps as they judge proper to supply the vacancy. None but *licentiates* or probationers, or those who have been previously inducted to another living, can be presented. The people have no right to elect a person to be presented to the presbytery; this right being reserved to the patrons, except when it is transferred by the patron to the parishioners. Yet the people are not overlooked; but have two ways allowed them of expressing their sentiments of the person who is to minister to them, either by subscribing or refusing to subscribe a paper, named a *call*, inviting him to be their minister; or by supporting a charge of immorality of conduct or unsoundness of doctrine. The former of these seems of little importance, as a *call* may be sustained, however small the number of subscribers. If no objection occur, the person is ordained, by imposition of the hands of the presbytery, who assemble at a time appointed for the purpose; the presentee having first answered the questions, and made the promises and engagements required by the law.

The lowest judicatory in the church of Scotland is the *kirk-session*, composed of the minister of the parish and of lay elders. New elders are chosen by the session, but are liable to be objected against by any member of the congregation. If the objections be not valid, they are at an appointed time set apart to their office by prayer; having first declared their assent to all that is contained in the confession of faith.

A presbytery is composed of an indefinite number of parishes; in some populous districts of not less than thirty, in some more remote of not more than four. This judicatory consists of the ministers of all the parishes within the district; of the professors of divinity, if they be ministers, in any university that is within the same district; and of one elder from each parish. A moderator, who must be a minister, is chosen twice a year. At present there are seventy-eight presbyteries in Scotland.

Three or more presbyteries, as the matter happens to be regulated, compose a *provincial synod*. There are at present fifteen of these judicatories, most of which meet twice in the year. This court is formed of every minister of all the presbyteries within the bounds of the synod, and the same elder who had last represented the kirk-session in the presbytery.

The next and highest ecclesiastical court is the *general* ASSEMBLY. It is composed in the following manner: all presbyteries consisting of twelve parishes, or under that number, send two ministers and one ruling elder; all presbyteries consisting of eighteen or fewer, but above twelve, send three ministers and one ruling elder; all presbyteries consisting of twenty-four parishes, or fewer, but above eighteen, send four ministers and two elders; all of above twenty-four, but under thirty parishes, send five ministers and two ruling elders; and all that consist of more than thirty parishes, send six ministers and three ruling elders. The sixty-six royal burghs of Scotland are represented in the general assembly by ruling elders: Edinburgh sending two, and every other burgh one; and each of the five universities is represented by one of its members. The general assembly, therefore, is composed of two hundred ministers representing presbyteries, eighty-nine elders representing presbyteries, sixty-seven elders representing royal burghs, five ministers or elders representing universities: in all 361. In this assembly, the sovereign is represented by the lord high commissioner. This assembly meets annually in the month of May, and continues to sit for

ten

ten days. But as it may be impoffible, in that fpace of time, to decide all the queftions that are brought before it, and circumftances may occur in the intervals between general affemblies requiring the interpofition of this fupreme court, a commiffion is annually formed of the general affembly: which differs from the general affembly chiefly in not being honoured by the reprefentation of the fovereign, and may be confidered as a committee of the whole houfe. Thirty-one members, of whom twenty-one are always to be minifters, conftitute a quorum, which meets four times in the year, or oftener, for the difpatch of bufinefs.

Thefe four courts are fo conftituted, that each inferior court is fubject to the controul of its fuperior. The power of the fuperior court may be exercifed at its own pleafure, upon reference from an inferior court, and upon appeal or complaint. In matters purely ecclefiaftical, the civil power does not interfere with thefe fpiritual courts; but in every queftion of a civil nature, fuch as refpect glebes, &c. the decifion of a prefbytery is cognizable by a civil judicatory.

The judicial power of the church of Scotland appears in the infliction or removal of fuch cenfures as are thought to belong to a fpiritual fociety. The objects of thefe cenfures are grofs immorality, herefy, and fchifm. The minifter of the parifh has no power of this nature, but as a member of the kirk-feffion: and he again is fubject to no control lefs than that of the prefbytery by whom he was ordained, and by whom alone he may be fufpended or depofed. The nature of thefe cenfures, and the method of inflicting them, are defined in a code of laws, confeffedly imperfect, called the form of procefs.

General laws were formerly made and repealed by the general affembly alone. The barrier act enables an individual to propofe to the prefbytery new laws, or the amendment or repeal of old laws. Such propofals muft be tranfmitted to the general affembly, and by them are either difmiffed, or fent to all the prefbyteries for their approbation. The refult is returned to the next general affembly, and paffes into a ftanding law, if not lefs than forty prefbyteries have approved. To prevent the delay which muft thus be occafioned, the general affembly, if it thinks fit, can order the propofed meafure to be obferved as a law, during the term which intervenes between its firft being propofed, and the rejection or confirmation of it by the prefbyteries at its fucceeding meeting.

The church of Scotland receives annually from the exchequer of that country, 2000 *l.* Of this, 500 *l.* are fet apart for the falaries of the procurator and agent of the church, the law-officers, clerks, &c.; and the remaining 1500 *l.* for the defraying of the expences incident to the dignified ftation of the reprefentative of the fovereign of the general affembly. Emoluments are alfo annexed to the offices of his majefty's chaplains for Scotland, and the deans of the chapel-royal. The ftipends of the minifters arife chiefly from the teinds or tythes, paid either in money or in kind by the titular of the teinds, who is not always the landholder, but in fome cafes the crown, in others an individual or a corporation. The landholder in Scotland enjoys a privilege in refpect of the payment of tythes, which is not known in other Chriftian ftates: he may value his teinds before a court of feffion; and that valuation being eftablifhed, how much foever the rent of his lands may rife by the improvements of agriculture, &c. the increafe is entirely his own, becaufe the teinds never go beyond the rate at which the valuation had fixed them. The landholder, if he be not titular, as is frequently the cafe, may compel the titular to fell the teinds to him; excepting where the teinds are held by the crown, or when they have been granted for the fupport of public inftitutions. If the titular does not pay the whole of the teinds, according to their valuation, to the minifter, the court of feffion may grant an augmentation, but never beyond the quantity or fum fixed when the teinds were valued. Befides the teinds, the minifter of every country parifh is provided with a dwelling houfe, or manfe; with a garden; with a glebe of not lefs than four acres of arable land; with grafs for one horfe and one cow, and with the out-houfes neceffary for the management of his fmall farm. By another legal provifion, called the ann, the half-year's ftipend that becomes due after the death of a minifter, is paid to his widow or executors. See Dr. Hill's Theological Inftitutes, part ii.

In a parallel drawn between the church eftablifhments of England and Scotland (fee Cove's Effay on the Revenues of the Church of England), we learn, that the whole provifion of the minifters of the Kirk of Scotland, was eftimated, about the year 1755, at about 68,500 *l.* per annum; which, being divided between 944 minifters, afforded to each of them, on an average, an annual income of 72 *l.* This provifion may, indeed, have been augmented fince; but it appears to be very incompetent to a decent and confortable maintenance, even in Scotland, and difcourages the youth of refpectable families and connections from entering, as they formerly did, into the miniftry.

Church, *High*, was a denomination originally given to thofe, otherwife called *Nonjurors*, who refufed to acknowledge the title of William III. to the crown of Great Britain, under a notion that James II. though excluded, was ftill their rightful fovereign. This appellation was given them, becaufe they entertained high notions of the dignity and power of the church, and the extent of its prerogatives and jurifdiction. And thofe, on the contrary, were called *low-church* men, who difapproved of the feceffion and obftinacy of the Nonjurors, diftinguifhed themfelves by their moderation toward diffenters, and were lefs ardent in extending the limits of church authority. The denomination of *high-church* men is now more generally applied to all who form pompous and ambitious conceptions of the authority and jurifdiction of the church, and who would raife it to an abfolute independence on all human power.

The non-jurors, or high-churchmen, who boaft with peculiar oftentation of their orthodoxy, and treat the Low-church as unfound and fchifmatical, differ in feveral things from the members of the epifcopal church, in its prefent eftablifhment; but they are more particularly diftinguifhed by the following principles: 1. "That it is never lawful for the people, under any provocation or pretext whatever, to refift the fovereign." This is called in England "paffive obedience," and is a doctrine warmly oppofed by many, who think it both lawful and neceffary, in certain circumftances, and in cafes of an urgent and momentous nature, to refift the prince for the happinefs of the people. They maintain further, 2. "That the hereditary fucceffion to the throne is of divine inftitution, and therefore can never be interrupted, confounded, or annulled, on any pretext." 3. "That the church is fubject to the jurifdiction—not of the civil magiftrate, but of God alone, particularly in matters of a religious nature." 4. "That confequently Sancroft and the other bifhops, depofed by king William III. remained, notwithftanding their depofition, *true bifhops* to the day of their death; and that thofe who were fubftituted in their places were the unjuft poffeffors of other men's property." 5. "That thefe unjuft poffeffors of ecclefiaftical dignities were rebels againft the ftate, as well as fchifmatics in the church; and that all, therefore, who held communion with them were alfo chargeable with rebellion and fchifm." 6. "That this

this schism, which rends the church in pieces, is a most heinous sin, whose punishment must fall upon all those who do not return sincerely to the true church, from which they have departed." Mosheim's Eccl. Hist. vol. v.

Church is also used for a Christian temple, built and consecrated to the honour of God; and, anciently, under the invocation of some particular saint, whose name it assumed.

In this sense, churches are variously denominated, according to the rank, degree, discipline, &c. as metropolitan church, patriarchal church, cathedral church, parochial church, cardinal church, &c. See each under its proper article, Metropolis, Patriarch, Cathedral, Parochial, Cardinal, &c. In ecclesiastical writers, we meet with grand church, for the chief church of a place, particularly in the Greek liturgy, for the church of St. Sophia at Constantinople, the see of the patriarch, founded by Constantine, and consecrated under Justinian. It was at that time so magnificent, that Justinian is said to have cried out in the consecration thereof, Ενικησα σε, Σολομων; *I have out-done thee, Solomon.* The dome, which is said to have been the first that was built, is 330 feet diameter.

The first church publicly built by the Christians, some authors maintain to be that of St. Saviour at Rome, founded by Constantine: others contend, that several churches abroad, called by the name of St. *Peter Vivus*, were built in honour of that apostle during his life-time.

In the first ages the Christians assembled for social worship in private houses and sequestered places: and therefore if any are pleased to give the name of a church to a house or part of a house, which, though appointed as the place of religious worship, was neither separated from common use, nor considered as holy in the opinion of the common people, it must be granted that the most ancient Christians had churches. It is the opinion of many learned men, particularly Suicer (ad vocem Ναος) that the Christians had no public edifices during the three first centuries, as they have shewn from the authorities of Origen, Minutius Felix, Arnobius, and Lactantius. Tillemont, in discussing the antiquity of Christian churches (Mem. Eccl. tom. iii. part 2) refers the first construction of them to the peace of Alexander Severus; but Mr. Moyle (vol. i.) ascribes it to the peace of Galienus. Between the years 211 and 249, during a calm of 38 years, Christians, it has been said, were permitted to erect and consecrate convenient edifices for the purpose of religious worship; to purchase lands, even at Rome itself, for the use of the community; and to conduct the elections of their ecclesiastical ministers in so public, but at the same time in so exemplary a manner, as to deserve the respectful attention of the Gentiles. Under the persecuting edicts of Dioclesian, the Christian churches were generally demolished; and though in some places the magistrates contented themselves with shutting up the places of religious worship, in others they proceeded to a more severe extreme; and after taking away the doors, the benches, and the pulpit, which they burnt, as it were in a funeral pile, they completely destroyed the remaining edifice. In the age of Constantine, the Christian temples of Antioch, Alexandria, Jerusalem, Constantinople, &c. displayed the ostentatious piety of a prince, ambitious in a declining age to equal the perfect labours of antiquity. The form of these religious edifices was simple and oblong; though they might sometimes swell into the shape of a dome, and sometimes branch into the figure of a cross. The timbers were framed for the most part of cedars of Libanus; the roof was covered with tiles, perhaps of gilt brass; and the walls, the columns, the pavement, were incrusted with variegated marbles. The most precious ornaments of gold and silver, of silk and gems, were profusely dedicated to the service of the altar; and this specious magnificence was supported on the solid and perpetual basis of landed property. In the space of two centuries, from the reign of Constantine to that of Justinian, the 1800 churches of the empire were enriched by the frequent and unalienable gifts of the prince and people. In the 10th century all Europe was alarmed with a terrifying apprehension, that the day of judgment was at hand, and that the world was approaching to its final dissolution; and, among the other effects of this general panic, the churches and monasteries were suffered to fall into ruin, or at least to remain without repair, from a notion that they would soon be involved in the general fate of all sublunary things. But when these apprehensions were removed, the tottering temples were rebuilt, and the greatest zeal, attended with the richest and most liberal donations, was employed in restoring the sacred edifices to their former lustre, or rather in giving them new degrees of magnificence and beauty. Accordingly, during the whole of the 11th century, all the European nations were diligently employed in rebuilding, repairing, and adorning their churches.

The churches of the first ages, however magnificent and splendid those of some favoured countries and places might have been, were generally plain and simple structures. Sulpicius Severus describes one of the churches of Cyrene in the deserts of Libya, which, he says, was made of small rods interwoven, not much more stately than his own house, in which a man could hardly stand upright; and the description given by our venerable Bede of the church which Finan, the second bishop of Lindisfarne, or Holy Island, since called the bishopric of Durham, built, will furnish a just idea of the simplicity of many of our oldest churches.

Places appropriated to religious worship were distinguished by a variety of names, both in the East and West. Εκκλησια and εκκλησιαστηριον, whence the French "Eglise," and the British "Eglwys," are often used indiscriminately, though sometimes, as we have already shewn in a preceding article, the former signified the assembly of Christians, and the latter the place where they assembled. One of the earliest names is "oratory" or "house of prayer," προσευκτηριον and οικος ευκτηριος, which names were afterwards restricted to chapels in private families. The Latins called the church "Dominicum" or "domus Dei," God's house; which answers to the Greek κυριακον, whence the Saxons derived their name "kyrick" or "kyrch," and the Scots and English "kyrk" and "church." Tertullian called it "domus Columbæ." The word "temple," which was not used during the three first ages, was introduced after the heathen temples were converted into churches for the worship of the true God. Mr. Bingham, in his "Antiquities," has collected a variety of other names, which we need not recite. Churches, which were built, after the persecutions ceased, over the grave of any martyr or saint, from respect to their memory, were called "martyrium" and "memoria," and thence the word "cemetery" came also to signify a church. This practice, perhaps, suggested the idea of dedicating these structures to some particular saint, and gave rise to the custom of putting some portion of the relics of a martyr into the foundation of every church, with a view of encouraging men to submit to a fate which was likely to befal them in those ages; and thence they proceeded to dedicate them to the honour of the Virgin, or to some remarkable circumstance in the life or sufferings of our blessed Lord. Mr. Bingham says that the word "mensa" was used for a church, because an altar or communion-table was erected at the place where the martyr suffered, at which sermons were preached;

preached; but this part seems rather to have answered to the "trapeza," a refectory in monasteries, where those discourses were held; these were never preached at the altar, which would have been very inconvenient for the auditors; the laity being never permitted to enter there.

A *church*, in order to be adjudged such by our laws, must have administration of the sacraments and sepulture annexed to it. If the king founds a church, he may exempt it from the jurisdiction of an ordinary; but it is otherwise in case of a subject.

The manner of founding churches in ancient times was as follows: after the founders had made their application to the bishop of the diocese, and had his licence, the bishop or his commissioners sat up a cross, and settled the boundaries of the church-yard where the church was to be erected, and then the founders might proceed with the building; and when the edifice was completed, the bishop consecrated it; then, and not before, the sacraments were to be administered in it. (See Stillingfleet's Ecclesiastical Cases.) But by the common law and custom of this realm, any person, who is a good Christian, may build a church without licence from the bishop, so that it be not prejudicial to any ancient churches; though the law takes no notice of it as a church, till it is consecrated by the bishop, which is the reason why *church*, and *no church*, &c. is to be tried and certified by the bishop. And in some cases, though a church has been consecrated, it must be consecrated again; as in case any murder, adultery, or fornication be committed in it, by which it is defiled; or if the church be destroyed by fire, &c.

The ancient ceremonies used in consecrating the ground on which it was proposed to build a church, and the church itself, were as follow: when the materials were provided for building, the bishop came in his robes to the place, &c. and having prayed, he perfumed the ground with incense, and the people sung a collect in praise of that saint to whom the church was dedicated; then the corner stone was brought to the bishop, which he crossed and laid for the foundation; and a great feast was made on that day, or on the day of the saint to whom it was dedicated; but the form of consecration was left to the bishop, as it is at this day.

A *Church* in general, legally considered, consists of three principal parts, viz. the belfry or steeple, the body of the church with the aisles, and the chancel; and not only the freehold of the whole church, but of the church-yard, are in the parson or rector; and the parson may have an action of trespass against any one that shall commit a trespass in the church or church-yard; as in the breaking of seats annexed to the church, or the windows, taking away the leads, or any of the materials of the church, cutting the trees in the church-yard, &c. But church-wardens may, by custom, have a fee for burying in the church; the church-yard is a common place of burial for all the parishioners. Moreover, the actions for taking away the seats must be brought in the name of the church-wardens, the parishioners paying the expence. If a person erect a pew in a church, or hang up a bell, &c. in it, they then become church goods, though not expresly given to the church; and he may not afterwards remove them. The parson only is to grant licence for burying in the church; but for defacing a monument in a church, &c. the builder or heir of the deceased may have an action. And a man may be indicted for digging up the graves of persons buried and taking away their burial dresses, &c. Although the parson hath the freehold of the church and church-yard, he hath not the fee-simple, which is always in abeyance; but in some respects the parson hath a fee-simple qualified. (Litt. 644, 645.) The chancel of the church is to be repaired by the parson, unless there be a custom to the contrary; and for these repairs he may cut down trees in the church-yard, but not otherwise. (Stat. 35 Ed. I. st. 2.) The church-wardens are to see that the body of the church and steeple are in repair; but not any aisle, &c. which any person claims by prescription, to him or to his house. Concerning these repairs the canons require every person who hath authority to hold ecclesiastical visitation to view the churches within their jurisdiction once in three years, either in person, or to cause it to be done; and they are to certify the defects to the ordinary, and the names of those who ought to repair them; and these repairs must be done by the church-wardens, at the expence of the parishioners. Can. 86.

By the common law, parishioners of every parish are to repair the church; but by the canon law, the parson is obliged to do it; and so it is in foreign countries, (1 Salk. 164.) In London the parishioners repair both the church and the chancel. The spiritual court may compel the parishioners to repair the church, and excommunicate every one of them till it be done; but those that are willing to contribute shall be absolved till the greater part agree to a tax, when the excommunication is to be taken off; but the spiritual court cannot assess them towards it. (1 Mod. 194. 1 Vent. 367.) For though this court hath power to oblige the parishioners to repair by ecclesiastical censures; yet they cannot appoint in what sum, or set a rate, for that must be settled by the church-wardens, &c. (2 Mod. 8.) If a church be down, and the parish is increased, the majority of the parish may raise a tax for the necessary enlargement of it, as well as the repairing of it, &c. (1 Mod. 237.) But in some law-books it is said, that if a church falls down, the parishioners are not obliged to rebuild it; though they ought to keep it in due repair. (1 Vent. 35.) On the rebuilding of churches, it is now usual, on the petition of the parishioners, to obtain briefs. See BRIEFS.

By stat. 37 Hen. VIII. c. 21, churches, not above six pounds a year in the king's books, may, by the assent of the ordinary, patron, and incumbent, be united; and by stat. 17 Car. II. c. 3, in cities and corporations, &c. churches may be united by the bishop, patrons, and chief magistrates, unless the income exceeds 100 *l. per annum*, and then the parishioners are to consent, &c. By stat. 9 Ann. c. 22. (See also stat. 10 Ann. c. 11.) 50 new churches were built in or near London and Westminster, for which purpose a duty of two shillings per chaldron was laid on coals; the rectors of these churches are to be appointed by the crown, &c. A duty is also granted on coals imported into London, to be appropriated for the maintenance of ministers for the new churches. Stat. 1 Geo. I. c. 23.

No man shall cover his head in the church, in time of divine service, except with a cap if he have some infirmity; and all persons are to kneel or stand, &c. as directed by the Common Prayer, during service. Can. 18. No ill language is to be used, or noise made in churches or church-yards; and persons striking, or laying violent hands on others there are to be excommunicated; and for striking with a weapon, or drawing a weapon with an intent to strike, shall lose one of his ears; nor may a man lawfully return blows in his own defence in these circumstances, stat. 5 and 6 Ed. VI. c. 4. 1 Hawk. P. C. c. 63, §. 24, &c. See BURGLARY and LARCENY.

No fairs or markets shall be kept in church-yards. Stat. 13 Ed. I. st. 2, c. 6.

Any person may be indicted for indecent or irreverent behaviour in the church; and those that offend against the acts of uniformity, are punishable either by indictment upon the statute, or by the ordinary.

Church, *Mother*, *Matrix ecclesia*. See Mother-churches.

Church, with regard to *Architecture*, Daviler defines a large oblong edifice, in form of a ship, with nave, choir, aisles, chapel, belfry, &c. See each part under its proper head.

Church, *simple*, is that which has only a nave and a choir.

Church *with aisles*, that which has a row of porticos, in form of vaulted galleries, with chapels in its circumference.

Church *in a Greek cross*, that where the length of the transverse part is equal to that of the nave; so called, because most of the Greek churches are built in this form.

Church *in a Latin cross*, that whose nave is longer than the cross part, as in most of the Gothic churches.

Church *in rotundo*, that whose plan is a perfect circle, in imitation of the Pantheon.

As to the form of the ancient Greek churches, when they had all their parts, it was as follows: first was the *narthex*, porch, or portico, and then the part called the *vaunt-nave*, προναος; this was adorned with columns on the outside, and on the inside surrounded with a wall; in the middle whereof was a door, through which they passed into a second portico. The first of these porticos was destined for the *energumeni*, and penitents in the first stage of their repentance; the second was much longer, destined for penitents of the second class, and the catechumens, and hence, called ναρθηξ, *ferula*, because those placed in it began to be subject to the discipline of the church. These two porticos took up about one third of the space of the church. From the second portico, they passed into the nave, ναος, which took up near another third of the church. In the middle, or at one side of the nave, was the *ambo*, where the deacons and priests read the gospel, and preached. The nave was destined for the reception of the people, who here assisted at prayers.

Near the entrance of this was the Baptistery, or Font. Beyond the nave was the choir, χορος, set with seats, and round: the first seat on the right, next to the sanctuary, being for the chantor, or *choragus*.

From the choir, they ascended by steps to the sanctuary, which was entered at three doors. The sanctuary had three apsides in its length; a great one in the middle; under which was the altar, crowned with a baldachin, supported by four columns. Under each of the small apsides, was a kind of table, or cupboard, in manner of a beaufet. Nevertheless, of the Greek churches now remaining, few have all the parts above described; most of them having been reduced to ruins, or converted into mosques.

M. Frezier, engineer to the French king, and F. Cordemoy, a regular canon, have disputed the form of the ancient and modern churches, and the best manner of building them, with a good deal of learning, in the Journals de Trevoux.

For the form of the Latin churches, though it be various, yet may all the variety be reduced to two heads; viz. those in form of a ship, and those of a cross.

Churches, *round*. Among the more ancient architectural structures of Great Britain which appear to have been connected in their origin as well as in their form, is one class, of which but few instances, if they were ever numerous, remain; known by the appellation of the Round Churches. Dr. Stukeley hazarded a conjecture, (Itin. Curios. p. 35.) that they were the most ancient churches in England; and were either erected in the later time of the Romans for Christian service, or in the earlier periods of the Saxons. Another opinion, equally strange, but far more general, was that which attributed the construction of them to the Jews.

The first writer who seems to have treated their real history with success, was Mr. Essex, whose "Observations" are to be found in the sixth volume of the Archæologiæ. But Mr. Britton, to whom more numerous sources of intelligence were open, appears almost to have exhausted the subject, in his "Architectural Antiquities," in which the principal of the round churches are both engraved and accurately described.

That the circular form for the temple was a very ancient one in the heathen world, may be proved from a variety of instances. Though nothing will be gained by comparing it either with the irregular structure of the Druid circle, or with the occasional temples of that form, which are found among the buildings of the Romans.

The round churches of this country appear to have been indebted for their origin to those who returned from the crusades; on whose minds the venerable form of the church of the sepulchre at Jerusalem had left a strong and durable impression.

The parent model had been rebuilt by Charlemagne about the year 812, to a certain extent, in imitation of the church of Santa Sophia at Constantinople: and the devotees of the cross, either considering it as the original work of Helena, the mother of Constantine the Great, or from the sacred relics it was supposed to have contained at a former period, appear to have adopted its form, not only in this country, but in others; considering it as one which was likely to exhibit a character of peculiar sanctity.

Santa Sophia, however, has at different times received accessions, and is now surrounded by a multitude of minarets which confuse the exterior outline of the rotunda. The church of the sepulchre at Jerusalem also has been enlarged: a second rotunda was added in the eleventh century by Godfrey of Bulloigne; and a tower at the west end, at a period much later. The best idea of it may be obtained from sir Robert Ainslie's Views in Egypt, Palestine, &c.

But a church still nearer to our own, both in design and character, is described by the German writer of "Voyage en Sicile et dans la Grande Gréce, addressé a l'Abbé Winckelman," 8vo. 1773. The account answers exactly to the churches of the same description in England.

"On donne l'Eglise du S. Sepulcre pour un temple antique; c'etoit une rotonde; cet edifice n'est point du bon tems de l'architecture: sa forme n'est pas parfaitement circulaire, et il n'y a point de portique à l'entrée, et il decrit un demi circle différent, qui ne fait point corps avec le reste du batiment; ce que lui donne une irregularité désagreable. L'on reconnoit aussi le mauvais goût du tems de la decadence des arts aux ornemens de l'ancienne porte qui est murée aujourd'hui. Cet edifice est vouté et soutenu entierèment par des colonnes de marbre."

Of the English round Churches, that of St. Sepulchre's, Cambridge, is supposed by Mr. Essex to be the oldest: he dates it between the first and second crusades, in the reign of Henry I. From the ground plan, with the interior and exterior views of the building, given by Mr. Britton, we perceive that it originally consisted of a circular wall perforated with six semicircular-headed windows, and an ornamented door-way of the same shape. The latter is still perfect; but the former appear to have been materially altered by widening, and the introduction of mullions. Within is a circular colonnade of eight columns. These are short and massy, without any base, and with a narrow ornamented capital, which varies in different columns. The tower ap-

pears

pears to have been raised one story, for the reception of bells, in the reign of Edward the Second; and the east end or chancel, with the north aisle, were added as late as 1313.

In regard to the history of St. Sepulchre's Church, Northampton, we are without authentic documents. It is universally asserted, that the circular part of the church was built by the knights templars, who obtained their organization and their fame in the vicinity of the church of the Holy Sepulchre at Jerusalem. Mr. Britton observes, that it advances a little in beauty of proportion from the church at Cambridge, and dates it at the end of the twelfth or the beginning of the thirteenth century. By the ground-plan and exterior view, he observes, it may be perceived that the walls of the circular building are thicker than those of the round church at Cambridge; that the columns are smaller and higher; that they have bases and capitals, some square and some round; that the circular aisle has no arched roof, but is merely covered with timber; and that, immediately above the columns, the wall becomes octangular. These are peculiarities which distinguish it from the other circular churches, and render it an unique example of ancient architecture.

In elegance of construction, the Temple church in London is far superior to those we have already mentioned. It seems to have been built upon the same plan with the old temple church in Holborn, the circular walls of which are said to have been discovered about a century ago, and was consecrated in 1185. The ground-plan and exterior wall of the round part are probably thus old; but the interior, with the six clustered columns, and their incumbent arches, as well as the choir, appear to have been erected about 1244, (when Sir William Dugdale tells us the church was again dedicated,) and correspond with the generality of those examples of ecclesiastical architecture which are known to have been erected in the reign of Henry the third. In raising the superstructure of the circular part, the architects appear to have mixed the new with the old style of arches.

Another church of the circular kind occurs at Maplestead in Essex; and still more instances may probably be found in remote corners of the kingdom. It is not unlikely, that the old church of St. Selpulchre, by Newgate, had the same form: and some allowance must probably be made for copies from the church of the Sepulchre taken at different periods.

According to a curious manuscript in the Bodleian Library at Oxford, a pilgrim who visited the Holy Land in 1462, upon his return, deposited the following curious articles in the abbey of Edyngton, in Wiltshire: "*A chapel made to the likeness of our Lord's sepulchre at Jerusalem*, and a variety of vestments, with imitations in wood of the chapel of Calvary, the church at Bethlem, the Mount Olivet, and the valley of Jehosaphat."

CHURCH, *discipline*, *government*, *policy*, *revenue*, &c. See these articles, and the preceding articles of *church of England*, &c. &c.

CHURCH *lands*, in *Agriculture*, are all such lands as belong to and are held under religious establishments. It has been observed by the author of "Modern Husbandry," that lands held by corporations, whether civil or religious, experience has proved are, in scarcely any instance, managed in such a way as to insure their permanent improvement. The writer of the "Report of the County of Lancaster" also remarks, that glebe or church lands, or any other appropriated to the support of meeting houses, and those lands which appertain to small livings purchased by the bounty of queen Anne, are generally under a bad state of cultivation, the uncertainty of lease depending on a contingency of a single life operating as a strong obstacle to any degree of even modern improvements, and, in consequence, they are in general under the very worst sort of management. This account of the management of church lands Mr. Donaldson thinks is strictly true, when applied to other parts of England as well as to the county of Lancaster. This, in some degree, proceeds from the want of some proper regulations in respect to the tithes. And he supposes that the modes of leasing lands, either for a term of twenty-one years, renewable on payment of a fine at the end of every seven, or on one or two lives, renewable on the demise of one of the persons named in the lease, on the payment also of an arbitrary fine, as practised by the dignitaries of the church of England, are well known to operate powerfully against the improvement of church-lands. It is impossible, says he, it should be otherwise, for who in his senses will think of expending money on the improvement of land, when these very improvements are to operate against himself at the renewal of a lease, which, in one case, is limited to seven years, and, in the other, is held on a very precarious tenure? Such regulations in regard to leasing church-lands, ought, he thinks, to be made, as would leave the tenants at liberty to expend part of their capitals in the improvements of their farms, without being compelled to pay a ransom at the end of every seven years for the improvements which their own money, labour, and industry, have effected in the intervals.

That something is necessary to be done in these cases, cannot be disputed by those who have seen the comparatively bad state in which much of the lands under such tenures still remains.

CHURCH *Bay*, in *Geography*, a bay on the S.W. coast of the Isle of Rathlin, at the N.W. extremity of Ireland. The ground in this bay is clean, and vessels can ride safe, except with westerly winds, which cause a great swell of sea there. M'Kenzie.

CHURCH *Creek Town*, a town of America, in the county of Dorchester, and state of Maryland, lying at the head of Church-creek, a branch of Hudson's river, 7 miles south-westerly from Cambridge.

CHURCH *Point*, a cape on the west coast of the island of Barbadoes; $\frac{3}{4}$ of a mile north of Hole Town.

CHURCH-*rate*. See CHURCH-*wardens*.

CHURCH-*reves*. See CHURCH-*wardens*.

CHURCH *Rock*, in *Geography*, a rock in the bay of Bengal, near the coast of Ava. N. lat. 17° 32′ E. lon. 94° 14′.

CHURCH-*scot*, or CHURCH-*esset*, in *Ecclesiastical History*, a payment, or contribution, so denominated in domesday, and by the Latin writers frequently called *primitiæ seminum*; being, at first, a certain measure of wheat, paid to the priest on St. Martin's day, as the first fruits of harvest.

This was enjoined by the laws of king Malcolm IV. and Canut. c. 10. But after this, church-scot came to signify a reserve of corn-rent paid to the secular priests, or to the religious; and sometimes it was taken in so general a sense as to include poultry, or any other provision that was paid in kind to the religious. From these customary oblations to the parish priest, the religious sometimes purchased an exemption for themselves and their tenants.

CHURCH-*Stretton*, in *Geography*, a small market town of Shropshire, England, is situated in a narrow, deep vale, between several high mountains: here are not above 100 houses, the greater part of which are occupied by day-labourers and small farmers. A free-school, church, and a decayed market-house or town-hall, are the only public buildings in this place. The mountainous ridges here are of great altitude, and furnish food to numerous flocks of small sheep: the wool and lambs of which constitute the chief incomes of the farmers and yeomen. On the top of the highest hill, called

Caer-Caradoc, is a large fortified entrenchment, which is traditionally said to have been the celebrated camp of Caractacus, the British monarch who so valiantly defended his kingdom against the warlike Romans. See CARACTACUS.

Here are a small weekly market on Thursday, and two fairs annually. It is 158 miles N.W. from London, and 13 S. from Shrewsbury.

CHURCH-*wardens*, anciently called CHURCH-*reves*, or *ecclesiæ guardiani*, the guardians or keepers of the church, and representatives of the body of the parish, are officers chosen yearly in Easter week, by the parson, and his parishioners, according to the custom of the place; to look to the church, church-yard, church-revenues, &c. observe the behaviour of the parishioners with regard to faults that come under the jurisdiction of the ecclesiastical court; present scandalous livers to the bishop; take care none preach without licence, &c. These officers are chosen by the joint consent of the parishioners and minister; but by custom, on which the right of chusing them depends, the minister may chuse one, and the parishioners another; or the parishioners may elect both. In most of the parishes in London, the parishioners chuse both church-wardens by custom: but in all parishes erected by stat. 9 Ann, c. 12, the canon (Can. 89, 90.) shall take place, and this directs the choice to be made by the joint consent of the minister and the parishioners; or, in case of disagreement, the minister shall chuse one, and the parishioners another. When the parishioners chuse, the majority of those who meet at the vestry, upon a written notice for that purpose, shall bind the rest: and by custom, the choice of church-wardens may be by a select vestry, or a particular number of the parishioners. The validity of the custom of chusing church-wardens is to be decided by the courts of common law, and not by the spiritual court.

All peers of the realm, and clergymen, members of parliament, aldermen, counsellors and attornies, physicians, surgeons and apothecaries, and dissenting ministers, are exempt from this office; and persons who have sued a felon to conviction, and the first assignee of the certificate thereof, are exempted from the office of church-warden, in the parish where the offence was committed. The same exemption extends to persons serving in the militia, during such service. Dissenters are allowed to execute the office by a sufficient deputy. No person living out of the parish, although he occupies lands within the parish, is eligible. A person, refusing the office, is liable to excommunication. They are sworn into their office by the archdeacon, or ordinary of the diocese, who is compellable by a mandamus to admit those whom the parish appoint.

The church-wardens are a kind of corporation: and are enabled by law to sue, and be sued, for any thing belonging to the church, or the poor of the parish.

They may purchase goods, but not lands, except by custom, in London, where they, with the minister, form a corporation for lands as well as goods, and may hold, purchase, and take lands for the use of the church, &c. If they waste the goods of the church, the new church-wardens (but not the parishioners) may have action against them, or call them to account. They have a certain special property in the organ, bells, parish-books, bible, chalice, surplice, &c. belonging to the church; of which, they have the custody on behalf of the parish, whose property they really are; and they may bring an action at law against those who steal or damage them. To them belongs the office, with the consent of the minister, of giving seats to the parishioners in the body of the church, reserving those who belong by prescription to particular messuages, &c. They have also the care of the benefice during its vacancy, and, as soon as there is any avoidance, they are to apply to the chancellor of the diocese for a sequestration: and when this is obtained, they are to manage all the profits and expences of the benefice for him that succeeds, and appoint a curate, approved by the bishop, to serve the benefice, and pay him out of the profits. It is their business also to summon a vestry, in order to settle any rates. Their duty comprehends a great variety of particulars, already noticed in the beginning of this article. To them it belongs to repair the church, and to make rates, and levies, with the consent of the parishioners, for this purpose. It is their province to provide, in conjunction with the overseers, for those who need assistance; to keep the key of the belfry, and to prevent the bells being rung without proper cause; to collect charity-money upon briefs; to give consent for burying a person in a different parish from that in which he dies; not to allow suicides or excommunicated persons to be buried in the church or church-yard, without licence from the bishop; and, by stat. 30 Car. II. c. 3. to apply to the magistrates for convicting offenders who do not bury their dead in woollen. They are also to take care that the church be well aired, as well as in good repair; to provide the proper books, as a large bible, a common prayer, and a book of homilies, a font of stone, a decent table, and other articles for the communion, and to see that the ten commandments are set up at the end of the church, &c. They are to sign the certificates of persons taking the sacrament as a qualification for offices. It is also their duty to prevent any irreverence or indecency in the church; and they may pull off a person's hat in the church, or turn him out if he disturb the congregation. They may refuse to open the church at the instance of any person, except the parson, or any one acting under him; they are not to suffer any one to preach, unless he appears qualified, by producing a licence. To them belongs the care of the church-yard as well as of the church; and they are to prevent all games and feasts, and profane usages, from taking place in either. Churchwardens are to levy the penalty of 12 *d.* on persons not coming to church each Sunday under stat. 1 Eliz. c. 2. They are to observe, whether the parson reads the thirty-nine articles twice a year, the canons once a year, preaches every Sunday good doctrine, reads the common prayer, administers the sacraments, &c. &c. They are also to superintend the conduct of the parishioners, with regard to their coming to church, having their children baptized, women churched, persons not marrying within the prohibited degrees, or without banns or licence, &c. &c. They are also by their oath to present, or certify to the bishop or his officers, all things presentable by the ecclesiastical law, which relate to the church, to the minister, and to the parishioners. To them belong the care and inspection of the parish register; and they are to levy penalties on those who profane the Sunday, under stat. 1 Car. I. c. 1. and 29 Car. II. c. 7. At the end of every year they are to deliver just accounts to the minister and parishioners; over which accounts, however, justices of the peace have no jurisdiction.

CHURCH-*yard*, a place adjoining to a church, employed commonly for the interment of the deceased. See COEMETERIUM.

CHURCHILL, JOHN, in *Biography*, duke of Marlborough, a prince of the holy Roman empire, one of the ablest statesmen and politest courtiers, as well as one of the most illustrious heroes that this, or, perhaps, any country ever produced, was the son of sir Winston Churchill, distinguished for his monarchical principles during the reigns of Charles I. and II. John was born at Ashe in Devonshire,

on

on Midfummer-day, 1650, and was educated in his father's houfe under a clergyman. When he was only twelve years old, his father took him to court, where the beauty of his perfon, the brilliancy of his underftanding, and the modefty of his behaviour recommended him to general notice. He became page and favourite to the duke of York, and in the year 1666, he was prefented with a pair of colours in the guards. His firft military fervice was at the fiege of Tangier, and from this time he feems to have devoted himfelf to the profeffion of arms. Upon his return to England, he continued his attendance at court, and received from the king, as well as from the duke, repeated marks of kindnefs and favour. He gained an intereft with the fair fex, though with fuch prudence as not to excite the jealoufy of any one. The duchefs of Cleveland, the king's favourite miftrefs, made him a prefent of 5000 *l.*, with which he immediately purchafed an annuity; and his favour with the duke of York was fecured by means of his fifter, who was miftrefs to that prince. In 1672, the duke of Monmouth commanding a body of Englifh auxiliaries in the fervice of France, Mr. Churchill attended him, and was foon after captain of the grenadiers in his grace's own regiment. He was engaged in all the actions of that campaign which humbled the republic of Holland. At the fiege of Nimeguen, captain Churchill fo diftinguifhed himfelf, that he obtained the particular notice of the great Turenne, who beftowed upon him the name of the "Handfome Englifhman." For his conduct at the fiege of Maeftricht he received the public thanks of the king of France; and the duke of Monmouth, in relating to his father what had happened at the attack, acknowledged that he was indebted to captain Churchill for much of his glory, and for his fafety altogether, fince his life had been preferved by his bravery. This good fortune, which began in his twenty-fecond year, attended all his fucceeding undertakings. The laurels which he brought from France, entitled him to preferment at home; he was accordingly promoted to a lieutenant-colonelcy by the king, and the duke made him gentleman of his bedchamber, and foon after mafter of the robes. As a courtier he acted his part with great warinefs, making his way through all the contending factions. In 1679, he accompanied the duke of York to the Low Countries; and in the next year he attended him into Scotland, where, as a declared favourite, he received every refpect from the nobility who wifhed to pay their court to the duke. While he waited upon the duke, a regiment of dragoons was given him, and, in a fhort time afterwards he married Sarah Jennings, a lady of great beauty and good connections, then an attendant upon the princefs, afterwards queen Anne. In the fpring of 1682, he fuffered fhipwreck with the duke of York in a paffage to Scotland, and obtained a fignal proof of his mafter's regard, in his folicitude to fave him, while a great part of the crew, and feveral perfons of quality were left to perifh. In the fame year, he obtained other preferments and a title, and on the acceffion of James II. to the throne he was fent ambaffador to notify the event to the court of France, and in a fhort time afterwards he was raifed to an Englifh peerage by the title of baron Churchill of Sundridge. Through the whole of this reign lord Churchill's conduct was regulated by the principles of prudence, and an invariable attention to his own intereft. He avoided public bufinefs, and, for a confiderable time, never declared himfelf. At length, when it was impoffible for a perfon of his rank and confideration to remain neuter, he made his decifion, and joined in the invitation to the prince of Orange. To obviate the charge of ingratitude, it is generally believed that he had often declared, if the king attempted to overturn the eftablifhed religion he would leave him; he never diffembled his zeal for the church of England, and had been taught from his infancy to regard it with the greateft reverence. The king, however, had no doubt of his fidelity, and entrufted him even with the command of 5000 men to oppofe the progrefs of the prince of Orange. James was advertifed of his difloyalty, but gave no credit to the report, till he, with the duke of Grafton, and fome other officers withdrew from the king's quarters, and joined the prince of Orange at Axminfter. By his advice, prince George of Denmark and the princefs Anne took the fame ftep. Lord Churchill was received with marks of efteem and refpect by the prince of Orange, and was, in the enfuing year, rewarded with the earldom of Marlborough. He affifted at the coronation of their majefties, and was foon after appointed to command the Englifh forces that were fent over to Holland, in order to make part of the army of the allies. He difplayed great military talents at the battle of Walcourt: and in the next year he ferved in Ireland with great reputation. The enfuing campaign he paffed on the continent with king William, where he exhibited great fagacity, by penetrating into the enemy's defigns of befieging Mons, in which the Dutch deputies were deceived. While he was proceeding by hafty fteps to the pinnacle of fame and of fortune, he received a meffage, without any warning, that the king had no further occafion for his fervices. This fudden deprivation of all his employments was followed by his commitment to the Tower, on a charge of high treafon. No evidence was brought againft him; he was bailed, and the principal author of the accufation, then a prifoner in Newgate, was convicted of perjury and punifhed, and the earl cleared. It is now generally believed that though no proofs were then brought forward againft the earl, yet a correfpondence had been carried on between him and the exiled king with a view of reftoring him to the throne. It is certain that, during the life of queen Mary, Churchill kept at a diftance from court, and attended, with his lady principally, to the princefs Anne, whofe influence probably prevented his intrigues from being inquired into. After the death of Mary, Churchill was made a privy counfellor, and, in 1698, was appointed governor to the dnke of Gloucefter: on this occafion the king very handfomely faid to the earl, "My lord, make him but what you are, and my nephew will be all I wifh to fee him." He continued in favour during the remainder of the reign, and received more than once the moft unequivocal marks of the king's efteem.

Immediately upon the acceffion of queen Anne to the throne in 1702, the earl of Marlborough was raifed to that height of power and greatnefs which left no fubject in Europe his equal. He attained to every honour to which ambition itfelf could afpire, and he gained lucrative appointments for his friends. He was created a duke, had a penfion granted him by the queen for her life, and received the thanks of parliament for his conduct abroad. This courfe of good fortune was balanced by the lofs which he fuftained in the death of an only fon, a youth of eighteen, then at Cambridge, but the duke fought and found relief in an active performance of the high duties of his ftation. We cannot follow this great and illuftrious general through all his campaigns, in which it has been faid, that he never drew his fword but victory purfued him. The bufinefs of 1704 was, however, fo celebrated, and was fo fignalized by the duke's mafterly execution of his own plans of pufhing to the Danube, that it muft not be paffed over. After a march of fifty days from the frontiers of Holland, he arrived, unexpectedly, at the lines of Schellenburgh, defended

 by

by 20,000 men, which he instantly attacked, and forced, after an obstinate resistance. This success brought on the famous battle of Hochlett, or as it is more generally called by us, the battle of Blenheim, fought August 2d, between the allied army commanded by the duke of Marlborough and prince Eugene, and the French and Bavarians, commanded by marshall Tallard and the elector of Bavaria. Nothing could be more complete than the victory on the side of the allies. The pride of Louis XIV. received a check which it never afterwards recovered, and the battle of Blenheim may be reckoned the date of that reverse of fortune which embittered the latter years of that monarch's life. The French were pursued till they crossed the Rhine, Landau was taken, and France trembled for its own safety. It is not possible to enumerate all the popular triumphs of the duke of Marlborough upon his return to England. The more substantial expressions of the nation's gratitude consisted in the public gift of the honour of Woodstock and hundred of Wotton, and the erection of a magnificent palace for his residence. The next campaign produced nothing worthy of public expectation, on which account discontents began to manifest themselves in England. The duke employed the latter end of the year in visiting the courts of Berlin, Hanover, and Vienna, where his talents for negociation were equally useful to the common cause, as his military talents in the field. No man ever displayed happier powers in conciliating different tempers and interests; to which a perfect command of himself, and the habitual practice of all the engaging arts of good-breeding greatly contributed. The emperor Joseph presented the duke with the principality of Mindelheim, which accompanied his title of prince of the empire. By great exertions he was able to meet the French army under marshal Villeroy, and on the 11th of May, 1706, he gained the decisive battle of Ramillies, and with that the reduction of all Brabant, with Antwerp and its territory. Ostend, Menin, Dendermonde, and Aeth, were added to the conquests of the year. On account of his successes, a bill was passed to settle his honours upon the male and female issue of his daughters.

The duke of Marlborough had now attained to the zenith of his glory. In the campaign of 1707, his antagonist was the celebrated duke of Vendome, by whom he was so well matched as to be able to gain no material advantage; and he was mortified in being unable to infuse a spirit of zeal, at a conference at Frankfort, in the German part of the confederacy. On returning to England, he had the still further mortification of finding his duchess supplanted in the affections of her mistress, by a new and more obsequious favourite. His own presence reclaimed the queen's attentions for a time, but the impression was made which at length put an end to his consequence. In the campaign of 1708, the French, under the dukes of Burgundy and Vendome, were defeated at the battle of Oudenard, by the superior skill of prince Eugene and the duke of Marlborough. Lisle was afterwards invested, which, though it resisted several months, at length, with its citadel, surrendered. The duke also recovered Ghent, Bruges, and other places taken by the French at the beginning of the campaign. France was now obliged to set on foot a negociation, and the duke of Marlborough, who had so often met and defeated her generals in the field, was appointed the queen's plenipotentiary, and went to Holland. The preliminaries proposed by the duke, in which he had carefully regarded the interests of the allies, were such as the French minister could not agree to, and the war was again renewed. The duke of Marlborough was now to contend with marshal Villars, a general of great experience and skill. The battle of Malplaquet was fought on the 31st of August, the French lines were completely broken, and the result was one of the most destructive actions of the whole war. It cost the allies 18,000 men, killed and wounded. The city of Mons was captured, but the purchase was reckoned too dear, even by those who were not accustomed to set a proper value upon human lives. The English nation, long accustomed to victory, began to lose its relish for triumphs, in which itself had no real or very apparent concern. The war became unpopular; the tory part of the country were loud in the clamours against its continuance, and the duke himself was slighted. His winter visit, though attended with public honours, was very inauspicious to the expectations which he had formed; he found that a total breach had been made between the queen and his duchess. He took the field again early in 1710, and, in conjunction with prince Eugene, conducted a campaign against marshal Villars, in which they captured several places of strength and importance. The duke's victories on the continent could not prevent the machinations of his enemies at home. The queen had called to her council men wholly inimical to his views. They wished and expected his resignation; but either private interest, or a desire of being absent from the scene of things in which he could take no part, or, perhaps, from a regard to the public interests of his country, he dissembled his indignation, and again met his antagonist Villars. In this campaign he maintained his superiority, but the advantages gained were neither very brilliant nor of very great consequence. His influence at court was now completely gone, still he seemed willing to retain his command in the army, but as he did not resign, the honour was taken from him. In the House of Commons he was charged with peculation, for which there was no such strong ground as should have induced his enemies to have pursued him with so much indignity. They were jealous of his power, and were determined to keep no terms with the man who had been so long and so deservedly regarded as the first person in the nation, and who, whatever might be his failings, merited the esteem and veneration of his country. To escape the mortification that he was liable to experience in his own country, he paid a visit, in the winter of 1712, to the Low Countries, where he was received with the honours due to his high character. In two years he returned, and upon the accession of George I. was again summoned to the court, and enjoyed the smiles of royal favour. He was re-instated in the supreme military command, and his advice was taken and acted upon with regard to the suppression of the rebellion in 1715. This was the last public business in which he took a part. His mental faculties began to droop, and he at length experienced those changes which are so humiliating to the human understanding, and which induce the state of complete second infancy. He died at Windsor lodge on the 16th of June, 1722, in the 73d year of his age, leaving behind him a numerous posterity by his four daughters, married into families of the greatest consequence in the kingdom. Biog. Brit.

Churchill, Charles, was the eldest son of the rev. Mr. Churchill, rector of Rainham in Essex; and when about eight years old he was sent to Westminster school. His proficiency in classical learning was considerable, but not so extraordinary as to entitle him to any pre-eminence over several of his school-fellows in the same class with himself. At the age of fifteen he became a candidate to be admitted on the foundation at Westminster, and went in head of the election. On entering his nineteenth year he quitted Westminster school, and applied for matriculation at the university of Oxford, but was refused on account of a deficiency in classical fical learning; he was however admitted of Trinity College, Cambridge, in the year 1749. Immediately after his admiffion he returned to Weftminfter, but quickly put an end to his education, by an imprudent marriage with a young lady in the neighbourhood. To this premature and highly inconfiderate meafure, moft of the difficulties in which our author was afterwards involved may be afcribed; and in his endeavours to forget or elude thofe difficulties he acquired fuch habits of diffipation, as indirectly terminated his life. His father, who had been reluctantly reconciled to this imprudent match, received this youthful couple into his houfe, where they refided about a year, during which the conduct of the fon was exemplary and domeftic. In the year 1751 he retired to the north of England, and applied himfelf to thofe ftudies which fhould qualify him for his future deftination in the church. At the age of twenty-two he again vifited the metropolis to take poffeffion of a fmall fortune to which he became entitled in right of his wife. He no fooner was inducted into the office of clergyman than he earneftly laboured from principle to difcharge the important duties incumbent on him. At twenty-five he was ordained prieft by Dr. Sherlock, bifhop of London; his family however increafing, he found the fcanty income of a curacy very inadequate to fupply his wants, and he opened a fchool and obtained confiderable encouragement; but in 1758, by the death of his father, he quitted the profeffion of an inftructor, and was elected his fucceffor to the curacy and lectureſhip of St. John the Evangelift, and in connection with this he engaged in private tuition, and gave leffons to the young ladies at Mrs. Dennis's boarding-fchool in Queen's fquare, and likewife in his leifure hours attended feveral young gentlemen in order to affift them in their claffical ftudies.

Such was the laudable conduct of this young man until he was twenty-feven years of age, when a total alteration took place in his general fyftem of conduct and behaviour in life. The anxiety arifing from domeftic infelicity unhinged his mind, though naturally of a firm texture, and feemed to give an entirely new bias to his difpofition. At this time the friendfhip between Churchill and Robert Lloyd, which had been formed at fchool, revived with all the glow of fenfibility and ardour of attachment characteriftic of men of ftrong paffions and of warm imaginations. Urged on by the fame motive, a reftlefs inquietude of mind, they hurried together into fcenes of diffipated conviviality. "The future, fays one of Mr. Churchill's biographers, is rarely facrificed to the prefent, without producing confequences of the moft diftreffing nature." A few months only had elapfed before the young man experienced, in the moft fenfible manner, the juftice of this obfervation. He found that by his extravagance and fondnefs for theatrical amufements he wantonly plunged himfelf into an abyfs of mifery, from which he had no hope of being ever able to extricate himfelf. At this critical and alarming juncture, Dr. Lloyd, father to his friend and companion, became his deliverer, and by his aid, Churchill was enabled to effect a compromife with his creditors, who upon receiving one fourth only of their feveral demands, fully liberated him from all the terrors of a prifon. He now ferioufly thought of exerting thofe talents which he well knew were latent in his mind; and his firft fubject was derived from the ftock of obfervation his habits of life had afforded him. The excellencies and defects of the actors in both houfes were the topics of his Rofciad, a poem publifhed in March, 1761, without his name. It was greatly admired, and was attributed to the moft celebrated names of the time; but a fecond edition declared the real author. Churchill was raifed to a confiderable fhare of eminence. As the characters he had drawn were public ones, the public at large became interefted in the difcuffion of their merits; and the feverity of the author's fatire was no impediment to the popularity of his work. Befides this, it had a very confiderable fhare of intrinfic merit. Equal energy and vivacity were difplayed in the delineations; the language and verfification, though not without inequalities, were fuperior to the ordinary ftrain of current poetry; and many of the obfervations were ftamped with found judgment and correct tafte. The theatrical performers increafed the celebrity of the piece by the impatience which many of them fhewed under its cenfure. The author juftified himfelf in a new piece of fatire, entitled the "Apology." Thefe works made him many enemies, but they brought him into the moft flattering notice among wits and men of pleafure. This produced its natural confequence of loofe and licentious manners. His nocturnal revels and frequent abfence from home rendered every return to it the more irkfome, and the frequent altercations between him and Mrs. Churchill, who poffeffed but little of the fpirit of conciliation, and whofe imprudence is faid to have kept too near a pace with that of her hufband, ended in February, 1761, in a total feparation. This circumftance, together with the general outcry raifed againft him by his parifhioners for the total difregard of his religious functions, and the unbecoming mode of his drefs, induced him to refign the curacy and lectureſhip of St. John's, which, but a few years before, had been conferred upon him, in confequence of the high character which he then poffeffed for learning and morality. He now totally renounced all claim to the clerical character, became a man of the town, and indulged in all the exceffes to which youth and unbridled licentioufnefs could prompt. To vindicate his conduct from the juft cenfure of the public, Churchill publifhed a poem, entitled "Night." The difgraceful impofture of the Cock-lane ghoft furnifhed him with another topic of perfonal fatire, which, however, did not greatly intereft the public.

In the year 1762, Churchill plunged deeper and more irrecoverably in the mire of debauchery and faction, by commencing an acquaintance with Mr. Wilkes, and by becoming a coadjutor in the North Briton, and it was given in evidence by the bookfeller, that the profits arifing from the fale of this publication were received by Churchill. He was included in the general warrant with Mr. Wilkes, and only efcaped, owing to the meffenger's ignorance of his perfon, and to the prefence of mind with which Wilkes addreffed him by the name of Thompfon. The political occurrences at the beginning of the prefent reign had infpired among the people a rancorous hatred againft the Scotch; and Churchill adminiftered food to this paffion by the "Prophecy of Famine," the materials of which were propofed to him as the fubject of a paper for the North Briton; but on more mature confideration, he determined on converting it into a poem, in which the powers of defcription are exhaufted in humorous exaggeration of the defects of the country, and acrimonious abufe of its inhabitants. The poem was received with avidity, and gave the author that precedence as a political fatyrift, which he long maintained at the expence of candour and decorum, and to the final debafement of his poetical as well as his moral character. Hogarth was the next victim immolated at the fhrine of party, on account of the attempts he had made to expofe the failings of the earls Temple and Chatham, and his coarfe caricature of Churchill himfelf. This epiftle was written in the author's beft manner, and is faid to have accelerated the death of the ingenious artift to whom it was addreffed.

Churchill now affected in his manners and drefs the appearance

pearance of a man of the town, and, in conformity to this exterior, he engaged in his illicit amours. He even proceeded to the fashionable vice of seduction, and enticed from her parents the daughter of a respectable tradesman in Westminster, for whom his passion subsided in less than a fortnight; during which short period she had full leisure afforded her for sorrow and repentance. Her father was induced to receive her again into his family: this instance of tenderness sensibly affected her, and her future conduct would probably have justified the lenient kindness of a father, had she not been continually exposed to the taunts and goadings of an elder sister, the bitterness of whose reproaches induced this unhappy young woman to apply once more to Churchill for protection, which he readily granted. While this transaction was fresh in the public mind, he published the "Conference," in which the emotions of a mind not hardened in guilt, and severely labouring under the pressure of self-conviction, are pathetically described, and several passages of that poem are strongly expressive of manly sentiment and acuteness of feeling. Accompanied by this young lady, he retired into Wales in the summer of 1763, the rusticity of whose inhabitants he has celebrated in his work, entitled, "Gotham." On his return to London, he found his friend, Lloyd, imprisoned in the Fleet, for whose liberation he made every possible exertion, but his efforts proved abortive. The rencontre between Wilkes and Martin gave rise to Churchill's next poem, entitled, "The Duellist," and he closed his poetical labours for the year 1763, with the "Author." The satire in this publication is of a general nature, and well directed. In 1764, he poured forth several new productions, inspired by no other muse than necessity, and accumulating all the faults, with few of the beauties of the former: these are entitled "The Candidate," "The Times," "Independence," and "The Journey." Towards the latter end of that year Churchill went over to France to pay a visit to Mr. Wilkes, then a refugee in that kingdom. At Boulogne he was seized with a fever, which soon threatened the fatal termination that took place on November 4th, 1764, which closed his short but animated career in his 34th year. His body was brought to Dover, where it was deposited in the old church-yard, with a stone over it, on which are inscribed his age, the time of his death, and this line from his own works:

"Life to the last enjoy'd here Churchill lies."

It is to his credit that he is much regretted by his particular friends, to whom he was endeared by a generosity of temper not unusually attending strong passions and unshackled manners. His poetical reputation seems to have been uniformly declining from the time of his death: a handsome edition of his works was, however, published in the year 1804, in two volumes, octavo, with explanatory notes, and an account of his life, to which this article is indebted. Churchill left two sons, Charles and John, the charge of whose education was generously undertaken by sir Richard Jebb, who sent the former to the university of Cambridge, with a handsome allowance. They neither of them proved worthy of this support. They inherited the faults, without the virtues and abilities of their father, and died, like him, victims to their disregard of temperance and prudence.

CHURCH-HILL, in *Geography*, a post and fair-town of Ireland in the county of Fermanagh. It is near Lough Erne, on the road from Enniskillen to Belleek, and is 89 miles N.W. from Dublin.

CHURCH-HILL, a village of America, in queen Anne's county, Maryland, at the head of S.E. creek, a branch of Chester river; N.W. of Bridge-town, and N.E. of Centreville eight miles, and 85 S.W. from Philadelphia. N. lat. 40° 9'. W. long. 75° 53'.

CHURCH-HILL *fort*, called also *Prince of Wales's fort*, a fort in New North Wales, at the mouth of Seal river, on the coast of Hudson bay, constructed in 1715. N. lat. 58° 55' 30". W. long. 94° 50' 45". The temperature of 12 months, from Sept. 1768 to the end of August 1769, was 24°.7. Phil. Trans. for 1770, vol. LX. p. 148, &c.

CHURCH-HILL *river*, a river of New South Wales, which runs north-easterly into the west side of Hudson bay, at Church-hill fort. N. lat. 58° 47' 32". W. long. 94° 7' 30".

CHURCHING *of women after child-birth*, took its rise from the Jewish rite of purification. In the Greek church it was limited to the fortieth day after delivery; but in the western parts of Europe no certain time is observed. There is an office in the liturgy for this purpose.

CHURCH-TOWN, in *Geography*, a village of America, in the N.E. part of Lancaster county, Pennsylvania, about 20 miles E.N.E. of Lancaster, and 50 W.N.W. of Philadelphia. It has 12 houses, and an episcopal church; and in the environs are two forges, which manufacture about 450 tons of bar-iron annually.

CHURCO, a town of Asiatic Turkey, on the coast of Caramania, about 46 miles from the isle of Cyprus.

CHURGE, in *Ornithology*, the name given by Buffon to the Indian bustard; he terms it *churge ou outarde moyenne des Indes*. See OTIS *bengalensis*.

CHURLE, CEORLE, or CARL, in *Saxon Times*, signified a tenant at will, who held of the thanes on condition of rent and service. They were of two sorts: one rented the estate like our farmers: the other tilled and manured the demesnes, and were called ploughmen.

CHURN, in *Rural Economy*, the name of a vessel in which cream is coagulated by agitation. There are various constructions or sorts of churns, but those which are of the upright or Dutch kind, and barrel churns, have been by much the most generally employed. Dr. Anderson observes that he should prefer the simplest which he has seen as the best; merely because they admit of being better cleaned, and of having the butter more readily separated from the milk than any others; these are the old-fashioned upright kinds, which have long handles with feet to them, perforated with holes for the purpose of beating the cream by means of being moved upwards and downwards by the hand. But though, for these reasons, he may prefer this form of churn, other persons may choose that which they like best, as all the sorts under skilful management will perform the business perfectly well. Indeed, where the cream has been properly prepared, the process of churning will be so easy, he thinks, as to render those utensils, in general, the most commodious which can be most easily emptied.

According to the author of the "Agricultural Survey of Cheshire," the churns in common use there are mostly of the upright sort, and have in some cases a lever applied to them, in which case, one end of it, which is supported by an upright frame, is connected to the end of the churn staff, and the other end of it by the means of a rod to the crank of a toothed wheel, and is wrought by a pinion fixed upon the axle of a common winch. By this simple contrivance, the operation of churning is performed by a single person with the greatest facility. But in large dairies, churns are frequently wrought by means of a horse, and on such farms as have threshing mills, they may be very conveniently attached to and wrought by them. But in whatever way the business of churning may be performed, the size of the churn should always be suited to the quantity of cream

cream intended to be churned, as without attending to this point, much lofs may frequently be incurred by the cream being forced out of the churn, as well as other caufes.

Several improvements have lately been made in this fort of machinery. Mr. Harland, by an alteration in the manner of working thefe utenfils, has in a great meafure obviated the inconvenience of the vertical motion of the common churn, and the awkward rotatory motion of the barrel churn; which is fupplied by a very eafy mufcular exertion, refembling in its nature that of a common pump-handle; and by affixing a fly-wheel, the agitation is performed in a more equable manner, and on that account the butter is more perfectly feparated from the whey. The effect of the fly-wheel in regulating motion may eafily be made evident by ceafing to work the handle, on which the churn, by a regular diminution of motion, continues to act for fome time without any moving power being applied. At *fig.* 3. *Plate* VIII. of *Agriculture*, is fhewn the common barrel-churn, thus improved, moved by the intervention of a multiplying-wheel, to moderate its over-violent motion. The head of the crank moving in the mortife in the handle, caufes the rotatory motion of the barrel with great facility. From fome experiments that have been made it would appear that if the barrel be fixed, and the axis in the infide, to which the dafhers are attached, be made to turn, that the forming of the butter will be much fooner completed than when the contrary is the cafe.

Churns with this fort of alteration have been likewife conftructed by the fame ingenious mechanic.

At *fig.* 4. is an improvement in communicating the vertical motion to the common churn. The fly-wheel and crank are applied as in the other inftance, and with the fame equable effects; which, from the vertical motion of the common churn being fo intolerably fatiguing, is a very valuable application. The limits of this vertical motion are obvioufly double the length of the crank whofe end is inferted in the mortife of the handle. The fame apparatus may be applied for making different quantities of butter by placing larger or fmaller churns on the fame platform.

Other improvements in thefe utenfils have been introduced by Mr. Rawntree, the principal advantages of which are, that the cream is more effectually agitated than in the common churns; that, by taking off the covers, the infide can be perfectly cleaned without any difficulty, and that by leaving them off, the churn will be kept fweet, when not in ufe, by the current of air paffing through it. A churn of this improved kind as fhewn in *fig.* 5, is compofed of two cylinders of tin plate (or, in large churns, of wood,) A, B joined together in an angle; thefe are ftrengthened by two bars of wood on each fide, covered with iron plates D, D, to which the centre pins *d*, that the churn turns upon, are affixed; the iron plates D, D, project beyond the wooden bars, and have holes through them to receive each end of a clamp *e*, which has a fcrew through the middle of it: the end of this fcrew preffes againft the middle of the cover E, fo that when the fcrew is releafed the clamp *e* can be taken away, and the cover removed. Each of the cylinders contains a beater, compofed of three circular boards, *fig.* 6, with holes through them, which boards are kept at the proper diftances from each other by a wooden rod fixed to them; *n n* is a fmall pipe extending from near the outer end of each cylinder to their junction where it connects with a fmall upright pipe; thefe anfwer the purpofe of the vent-peg, and can always be kept open without throwing out the cream. When this churn is ufed, one of the beaters muft be put into its cylinder, and its cover put on and fcrewed faft; the churn muft be then held by one perfon, fo that the clofed cylinder is nearly vertical, (as in the figure) while another pours the cream in at the other end, which is left open; the other beater is then put in and the cover fcrewed on. The operation of churning is performed by a perfon taking hold of any part of the churn, and moving it up and down on its centre pins, fo that the elevated cylinder is a little above the horizontal line, (large churns are put in motion by a pendulum affixed to the end of one of the centre pins). By this means the cream is alternately poured out of one cylinder into the other, and dafhed againft the beaters with great violence. When the butter is made, the butter-milk is drawn off by a peg in one of the covers, and the butter is taken out by removing the covers. And an improvement of his on the upright churn is exhibited at *fig.* 7, by which the operation of churning is faid to be executed with much greater eafe and expedition.

The *pendulum churn* conftructed by Mr. M'Dougall has been found to anfwer admirably well, and fave much labour in Mr. Curwen's dairy in Cumberland.

As the improvements of Mr. Harland render the expences of churns confiderably higher, it may not be unufeful to ftate the addition which is thus created. A barrel-churn, which will make four dozen of butter, ufually cofts about 3*l.* 10*s.*, but, with the improvement, five guineas; the common upright churn, with the additional apparatus, will coft two guineas, when for making eight pounds at a time; and three guineas for making twelve pounds, and fo on in proportion to the fize. Thefe churns may be had of the manufacturer in Fenchurch-Street, London.

Churn-*owl*, in *Ornithology*. The common European goatfucker has obtained the name of churn-owl in many parts of England; and it is alfo called the goat-owl and fern-owl. Ray defcribes it in his Synopfis under the name of churn-owl; and Willughby under the two latter. At this time it is pretty generally known to be of a diftinct genus from the owl tribe; it is the *Caprimulgus europæus* of modern naturalifts. See article Caprimulgus.

CHURNET, in *Geography*, a river of England, which runs into the Dare in Staffordfhire.

CHURNING, in *Rural Economy*, the operation of procuring butter by the agitation of cream in a veffel of the churn kind. It has been well noticed by Dr. Anderfon, that in the management of this procefs much greater nicety is requifite than has been commonly fuppofed; as a few hafty irregular ftrokes given by the dafhers may render the whole of the butter of that churning ufelefs in its original intention, and of little or no value for any other purpofe, which, but for that circumftance, would have been of the firft quality. It is therefore conceived that the proprietors of extenfive dairies fhould be particularly attentive to the execution of this part of the bufinefs, and be very careful in providing a proper perfon for the conducting of it.

The moft fuitable conductors of operations of this nature are thofe of cool, fedate, fober difpofitions, and no others fhould ever be permitted to take any fhare in the performance of this fort of bufinefs without a conftant attention to the manner in which it is executed, as without fuch care much lofs and inconvenience may often be fuftained by the dairy farmer.

And, it is added, that to thofe who have been in the habit of feeing cream churned that has not undergone a proper preparation, it may perhaps be thought that it muft be hard labour in a confiderable dairy to be executed by one perfon; but that nothing is more eafy, fo far as bodily labour is concerned, than the procefs of churning butter where the cream has been prepared in a fuitable manner.

Mr. Headrick made the following chemical experiment as to the procefs of churning, which is recorded in the Report of of Mid-Lothian. "From the fwelling and foaming of the liquor during this procefs, he was led to conclude that gafes were evolved from it."

And "to afcertain that point, a glafs tube was faftened in a plug of cork, fixed in the funnel of a patent churn belonging to Mr. Robertfon at Granton. The lower extremity of the tube was immerfed in water, and the joints of the funnel and cork luted, fo as to prevent the accefs of external air and caufe the gafes emitted by the liquor to pafs through the tube into an inverted glafs jar, previoufly filled with water.

"To their great furprife, no gafes whatever were (he fays) emitted during the procefs; and the water in the bafon conftantly rofe in the glafs tube; which fhewed that the atmofpheric air was rufhing into the liquor inftead of gafes rufhing from it, as they expected, into the atmofphere."

The conclufion which feems to follow from this experiment is, he thinks, "that in churning, the faccharine part of the milk combines with the oxygen of the atmofphere, by which it is converted into acid, and precipitates the oil, or butyraceous part." He adds, that "this experiment might give rife to many important obfervations concerning the nature and management of milk; but it fhould be previoufly repeated, with varied circumftances, in order more fully to afcertain the facts."

It has been fuggefted by fome, that the procefs of churning might be greatly expedited by having recourfe to the ufe of acids, fuch as diftilled vinegar, towards the latter part of the operation; but it is probable that fuch additions can never be made without confiderably injuring the quality of the butter. Befides, nothing feems to be neceffary to the eafy and expeditious execution of the bufinefs, but a due temperature and ftate of acidity in the cream, the manner of attaining which is fully explained in fpeaking of the nature and management of the dairy. See DAIRYING.

For various methods of churning or making butter among the ancients and in the Eaft, fee BUTTER.

CHURR-WORM, in *Entomology*, a name given by fome to the *Gryllotalpa*.

CHURRITUCK, in *Geography*, a county of America, in the ftate of North Carolina, and diftrict of Edenton.

CHURSEN, a town of Arabia; 32 miles N.E. of Chamir.

CHURWALDEN, a diftrict of Switzerland, in the league of the Ten Jurifdictions, purchafed of the houfe of Auftria in 1649. In this diftrict the hamlets are pleafantly difperfed about the vale and upon the fides of the mountains.

CHUSAN, CHEW-SHAN, or TCHEOU-CHAN, an ifland, or rather a groupe of iflands, fituate in the Eaftern fea, about 18 or 20 leagues from Ning-poo, between the province of Tche-tchiang, the eaftern coaft of China, and Japan. N. lat. 30°. E. long. 122°. At the harbour of the principal of thefe iflands the Englifh firft landed on their arrival at China; and this was formerly reckoned the utmoft boundary of European navigation. The fea from thence, for about 10° of latitude and 6° of longitude, was utterly unknown before the late embaffy, the fquadron of which touched at this ifland in 1793, except to thofe who dwelt in the neighbourhood of its fhores. Into this fea are received the waters of the great "Whang-ho," or Yellow river of China. See YELLOW *Sea*. Between the Queefan iflands and Chufan harbour, through a fpace of about 60 miles in length, and 30 in width, the number of iflands exceeds 300. The part of the harbour in which the Clarence, one of the fhips of the Britifh fquadron, anchored, was about half a mile diftant from a landing place, and the depth of water was five fathoms. In this fituation the four paffages into the harbour were fo fhut in, that none of them were vifible. It appeared like a lake furrounded by hills; the extent of the harbour, from north to fouth, is little more than a mile, and near three miles from eaft to weft. The rife and fall of the tides make a difference of about 12 feet. The time of high water, at the full and change of the moon, appears to be about 12 o'clock. The tides, however, are very irregular, and vary, according to the wind, and the eddies produced by fuch a multiplicity of iflands.

Among thefe numerous iflands there are almoft as many valuable harbours, or places of perfect fecurity, for fhips of any burden. This advantage, together with that of their central fituation, in refpect to the eaftern coaft of China, and the vicinity of Corea, Japan, Leoo-keo, and Formofa, attract confiderable commerce, efpecially to Ning-poo, a city of great trade in the adjoining province of Tche-tchiang, to which all the Chufan iflands are annexed. From one port in that province twelve veffels fail, annually, for copper to Japan.

Moft of the Chufan iflands confift of hills rifing with a regular flope, and rounded at top, as if any points or angles, exifting in their original formation, had been gradually worn off into a globular and uniform fhape. Many of thefe iflands, though clofe to one another, are divided by channels of great depth. They reft upon a foundation of grey or red granite, fome part refembling porphyry, except in hardnefs. They were certainly, fays fir G. Staunton (Embaffy, vol. i. p. 408), not formed by the fucceffive alluvion from the earth brought into the fea by the great river, at whofe mouth they are fituated, like the numerous low and muddy iflands at the mouth of the Po, and many others; but fhould rather be confidered as the remains of part of the continent thus fcooped and furrowed, as it were, into iflands, by the force of violent torrents carrying off, farther into the fea, whatever was lefs refiftible than the adjacent rocks. Some of them wore a very inviting afpect; particularly *Poo-too*, which fee.

CHUSARIS, or CHUSARUS, in *Ancient Geography*, a river of Africa, in the interior of Libya, according to Ptolemy.

CHUSII, or CISII, a people of Afia, in Sufiana, S.W. of the town of Sufa between this and Pafitigris.

CHUSIS, CHUZES, or CHISAS, an epifcopal fee of Africa, mentioned in the acts of the council of Carthage, held under Cyprian.

CHUSISTAN, or KHOSISTAN, in *Geography*, a province of Perfia, bounded on the north by the Irak Ajemi, on the eaft by Farfiftan, on the fouth by the Perfian gulf, and on the weft and fouth-weft by the Tigris, which feparates it from the Arabian Irak. This is the fame country with Cufh in Affyria, having preferved its ancient name with a Perfian termination, and correfponds to the ancient Sufiana. But the name is antiquated. Shuftec, or Toftac, is now the name of a large province. Loriftan, or Laureftan, is in Shuftec; and to the weft is the country of Havila, the Ahwaz of M. D'Anville. The country, thus denominated, is extenfive, but thinly inhabited. It produces corn, rice, cotton, fugar, tobacco, and dates. The northern part is mountainous, but the fouthern flat and marfhy.

CHUSKA, a town of Afia, in the country of Tibet; 25 miles W.S.W. of Tankia.

CHUTA-NAGPOUR, a town of Hindooftan, in the country of Bahar; 150 miles S. of Patna, and 190 W. of Calcutta.

CHUTÆI, in *Ancient Geography*, a people originally of Affyria or Sufiana. Salmanazar tranfported them into the country

country of Samaria, in the room of the Israelites; they were then idolaters, and he appointed priests to instruct them in the worship of the God of Israel; but they attempted to blend idolatry with the religion of the Hebrews. Under Alexander the Great they obtained permission to build a temple on mount Gerizim. Josephus.

CHUTE, in *Geography*, a river of England, which runs into the Avon, near Bath.

CHUWASCH, a town of Persia, in the province of Segestan; 70 miles S.E. of Zareng.

CHUZIS, in *Ancient Geography*, a town of Africa propria, placed by Ptolemy between the two Syrtes.

CHWASTOW, in *Geography*, a town of Poland, in the palatinate of Kiov; 40 miles S.S.W. of Kiov.

CHYDA, in *Ancient Geography*, a town of Asia Minor, in Lycia, according to Ptolemy.

CHYDAS, a river of Sicily. Ptol.

CHYLE, in *Anatomy*, is the fluid into which the food is converted in the small intestine. See DIGESTION.

CHYLE, in *Chemistry*. The food of animals, after it has undergone digestion in the stomach, passes into the duodenum (the first of the small intestines), and here a separation begins to take place, the *chyle*, or nutritive part of it, being absorbed by the *lacteals*, which are minute absorbent vessels which open within the cavity of the small intestine, whilst the other portion of the food passes down into the large intestines. Chyle, therefore, is the last change that food undergoes previous to its conversion into blood, for the lacteals convey it by a circuitous course into a common reservoir, the *thoracic duct*, which opens into the left subclavian vein not far from the heart. The chemical analysis of chyle would be scarcely less interesting than that of blood itself, could it be collected in sufficient quantity, but this is attended with great trouble, as it would be scarcely possible to collect from one animal a greater quantity of *healthy* chyle than what would be found in the thoracic duct when the animal was killed a few hours after making a hearty meal. Hitherto only a few desultory experiments have been made on pure chyle, which have been collected by Haller.

By these we learn that chyle is a milky white fluid, of an agreeable sub-saline taste, lighter than the serum of blood, and even than water, on the surface of which it swims like cream. It readily coagulates by rest and extravasation, and appears to be composed of water, of an oily substance, consisting of globules evident to the microscope, of a heavier matter, like cheese, which remains at the bottom after coagulation, and of some earth. Chyle readily turns sour by keeping, but when fresh it gives no signs of acidity. The nature of the aliment makes but little change in that of the chyle. Its colour is usually white, as is obvious by the whiteness and turgescency of the lacteals, if examined after digestion; but Dr. Fordyce found that indigo, introduced in fine powder into the stomach, was capable of giving a blue tinge to the chyle. For further observations as to the time and mode of its formation, see the article DIGESTION.

CHYLEMETH, in *Ancient Geography*, a river of Africa, in Mauritania Cesariensis, according to Ptolemy.

CHYLIFICATION, is the process by which the conversion of the food into chyle is effected. See DIGESTION.

CHYLONGO. See CHILONGO.

CHYLOSIS. See CHYLIFICATION.

CHYME, is that particular modification which the food assumes after it has undergone the action of the stomach. See DIGESTION.

CHYME, in *Chemistry*. All food is reduced in the stomach by the united action of the fibres of this organ and of the gastric juice into a white pulpy mass, in which all the digestible parts of the aliment are indistinguishably blended, and which is called *chyme*. It is probably after this period that the *chyle* begins to be separated. The formation of chyme is so intimately connected with the subject of *digestion*, that we shall refer our readers to this article.

CHYMISTRY. See CHEMISTRY.

CHYMOLOGI, among *Botanical Writers*, denote such as have employed their time in investigating the qualities and properties of plants from their taste and smell.

CHYMOSIS, in *Physiology*, formed of χυμος, *succus*, of χεω, *fundo*, *I melt*, the act of making or preparing *chyme*, which see.

CHYMOSIS, in *Surgery*. See CHEMOSIS.

CHYTLA, in *Antiquity*, a liquor made of wine and oil, and sometimes used in divination.

CHYTRACULIX, in *Botany*, Brown. Jam. See CALYPTRANTHES *chytraculix*.

CHYTRÆUS, DAVID, in *Biography*, a learned Lutheran divine, born at Ingelfing, in Suabia, in 1530, was distinguished for his application to theology and the belles lettres, of which he became a professor at Rostock. He died in 1600. He was a considerable author; but his principal piece was a "Commentary on the Apocalyse." His Latin chronology of Herodotus and Thucydides is also in some repute. All his works were collected and printed at Hanover, in 1604, in two volumes folio. His brother, Nathan, presided over an academy at Bremen: he acquired some reputation for his Latin poems.

CHYTRI, among the Athenians, a festival in honour of Bacchus and Mercury, kept on the 13th of the month Anthesterion.

CHYTRI, in *Ancient Geography*, a town of the island of Cyprus, according to Pliny and Steph. Byz., called by Ptolemy *Chytros*, which had been episcopal.—Also, a lake of Greece, in Bœotia, placed by Theophrastus in the canton called "Pelecania," between the rivers Melas and Cephisus.—Also, a place situated at Thermopylæ, in which were hot baths. Pausanias, who speaks of these baths, says, that the people of the country called them χυτρους γυναικειους, *chytres*, or *baths of females*.

CHYTRINUM, or CHYTRIUM, a place of Asia Minor, in Ionia, belonging to the inhabitants of the isle of Cos.

CHYTROPOLIA, a place of Asia, in the vicinity of the burgh of Telephe, supposed to be situated towards the Phasis in Armenia Major.

CHYTROPOLIS, a small country of Thrace. Steph. Byz.

CHYTRUS, CITRIA, a town of the island of Cyprus, at some distance from the northern coast, S. of Marcaria, and N.W. of Salamis.

CIA, or DIA, an island of the Ægean sea, near that of Crete. Pliny.

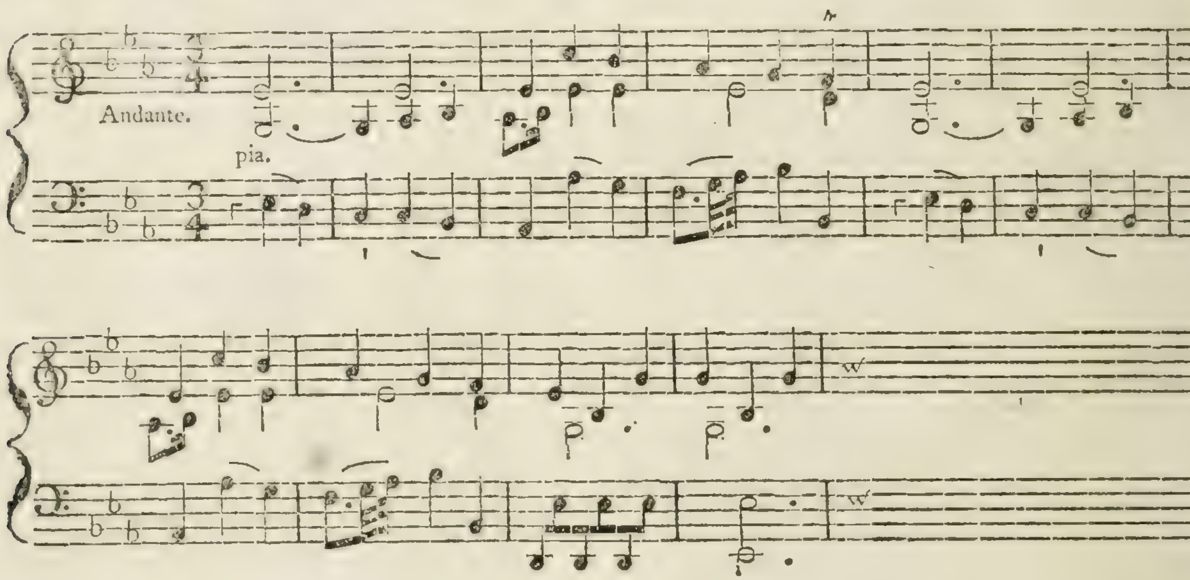
CIABRUS, CIAMBUS, CIAMBRUS, or CEBRUS, *Zibriz*, a river of Mœsia, dividing it into the higher and lower, running towards the north, and discharging itself into the Danube.

CIACA, a town in that part of Cappadocia, which was afterwards called Armenia Minor; situated in the Melitene, upon the right bank of the Euphrates, almost opposite to Pastona. Ptolemy calls it *Ciacis*.

CIACCONA, in *Music*, in Italian means the same thing, with *Chaconne* (which see) and is of so ancient an invention, that the origin of the term is disputed. Frescobalds has composed variations on the ciaccona; and a whimsical composer of Bergamo, Il Cavalier Tarquinio Merula, in a volume of his works published in 1635, has a composition which he calls "Duo sopra la Cieccona," on a grand base. Etymologists are doubtful whence the

the word *chaconne* or *ciacconna* is derived; it has been imagined in Italy by ſome that a *cieco*, or blind fidler, had invented the air, and that it had its name from that circumſtance. And we are able to give ſome weight to this conjecture, from recollecting, that in the "Hiſt. of Muſ. vol. ii." there is an account of a celebrated blind organiſt, who flouriſhed at Florence ſo early as the middle of the 14th century, and who was probably author of the air upon a ground, called the *cieccona*, or *ciacconna*. Philip Villani, the youngeſt of the Florentine hiſtorians of that name, in his "Vite d'Uomini illuſtri Florentini," has inſerted the life of Franceſco Cieco, the blind organiſt, who died in 1390. "Many," ſays this writer, "are the Florentines who have rendered themſelves memorable by the art of muſic; but all thoſe of former times have been far ſurpaſſed by Franceſco Cieco, who ſtill lives; and who, during childhood, was deprived of ſight by the ſmall-pox. He was the ſon of Jacopo, a Florentine painter, of great probity and ſimplicity of manners; and being arrived at adoleſcence, and beginning to be ſenſible of the miſery of blindneſs, in order to diminiſh the horror of perpetual night, he began in a childiſh manner to ſing; but advancing towards maturity, and becoming more and more captivated with muſic, he began ſeriouſly to ſtudy it, as an art, firſt by learning to ſing, and afterwards by applying himſelf to the practice of inſtruments, particularly the organ, which he ſoon played, without ever having ſeen the keys, in ſo maſterly and ſweet a manner, as aſtoniſhed every hearer. Indeed, his ſuperiority was ſoon acknowledged ſo univerſally, that, by the common conſent of all the muſicians of his time, he was publicly honoured at Venice with the laurel crown for his performance on the organ, before the king of Cyprus and the duke of Venice, in the manner of a poet laureat."

As the beautiful chaconne by Jomilli, which terminated a grand ballet at the Opera Houſe in 1772, and in which Mademoiſelle Heynel diſplayed her unrivalled powers of grace and execution, is not yet forgotten, we ſhall here inſert a few bars of it, as an admirable ſpecimen of the kind of movement ſo called.



CIACICA, in *Geography*, a juriſdiction or province of Peru, in S. America, ſubject to the archbiſhop of Plata; about 90 leagues N. of the city of Plata, and 40 from Paz. Its capital, which has the ſame name, and all the places ſituated to the ſouthward of it, belong to the archbiſhopric of Plata; but many of thoſe that lie to the north of it are in the dioceſe of Paz. The countries in this juriſdiction extend in ſome parts above a hundred leagues, and, of courſe, the temperature is various. Some parts are very hot, and produce abundance of *coca*, (which ſee,) affording a conſiderable commerce, and ſupplying all the mine towns from Charcas to Potoſi. The colder parts feed large herds of cattle; together with vicunas, guanacos, and other wild creatures. This province has alſo ſome ſilver mines.

CIACONIUS, Alphonso, in *Biography*, born at Baeça, in Andaluſia, about the year 1540. He entered the order of the Dominicans, and was afterwards ſent to Rome, where he was created titular patriarch of Alexandria. He wrote ſeveral works, ſome of which prove him to have been exceedingly credulous and ſuperſtitious, ſuch was his treatiſe to confirm the ſtory of the delivery of Trajan's ſoul from hell by the prayers of pope Gregory the Great. His moſt eſteemed work is entitled, "Vitæ et Geſta Rom. Pont. et Cardinalium," which he did not live to finiſh. It was completed by his nephew, and publiſhed in 1602. It abounded with errors, and the reviſion of it was committed to Jerome Alexander, and Vittorelli, and the corrected edition appeared in 1630. The laſt edition was greatly enlarged, and publiſhed in 4 vols. folio, at Rome, in 1676. Ciaconius left in MS. "An univerſal Library of Authors," which was edited, with additional notes, by Camuſat, and printed at Paris in folio, in 1732.

CIACONIUS, Peter, brother of the above, was employed by pope Gregory XIII. in reviſing an edition of the Bible, and of other works then printing at the Vatican. For ſuch an employment he is ſaid to have been admirably fitted, on account of the extraordinary facility which he had of reſtoring mutilated paſſages, and illuſtrating obſcurities. He is celebrated chiefly as a commentator, but he was engaged with Clavius in a correction of the calendar, and, after his death, were publiſhed a poſthumous work of his, entitled, "Kalendarii Romani veteris Explanatio," and ſome ſmaller pieces. He was connected with, and highly eſteemed by, the principal literati of his time, and was accounted

counted among the moſt learned men of the age in which he flouriſhed. He died at Rome in 1581. Gen. Dict.

CIÆNA, or CINNA, in *Ancient Geography*, a town of Aſia Minor, in Galatia. Ptolemy.

CIAGESI, or CIAGISI, an ancient people, who occupied one of the more ſouthern parts of Dacia.

CIAIS, a town of Mingrelia, near the Black Sea.

CIALIS, a country of Independent Tartary, with a capital of the ſame name; bounded on the N. by Eluth, on the E. by ſandy deſerts, on the S. by the Greater Tibet, and on the W. by Turkeſtan.

CIAMBERLANO, LUCA, in *Biography*, a painter and engraver, native of Urbino, whoſe prints bear date from 1609 to 1628. His engravings are executed entirely with the graver, in a neat but ſtiff manner: he drew the figure with tolerable correctneſs; but the effect in his prints is much injured by the lights being too much ſcattered, and of equal ſtrength; this, however, is the fault of the time when he lived. Many of his prints are from his own compoſition, and others from Raffaele, Polidor, Caracci, &c. Strutt. Heinecken.

CIAMBETTA, in *Ichthyology*, one of the ſynonymous names of the balance-ſhark, *Libella ciambetta*, Salvian, Aq. See SQUALUS *zygæna*.

CIAMPA, in *Geography*. See CHIAMPA and SIAMPA.

CIAMPELLI, AGOSTINO, in *Biography*, an hiſtorical painter, born at Florence about 1578. He became the diſciple of Santo di Titi, the moſt eminent Florentine painter of that time, and from him imbibed a ſufficiently correct and pure ſtyle of drawing, together with the gay colouring then in uſe among his countrymen. His pictures are, however, a little too red, and ſometimes rather hard. He neverthele ſs acquired ſufficient reputation to occaſion his being employed at Rome under Clement VIII. and his ſucceſſors, upon many large works in freſco, and in oil, which are enumerated by Baglione. The Sacriſty, and the chapel of S. Andrea, in the church of Geſu, are amongſt his beſt works in freſco; and a picture in oil by him at St. Stefano in Peſcia, repreſenting the meeting of Mary and Elizabeth, is conſidered little inferior to another by Tiarini, placed near it. Towards the latter part of his life, he was honoured by the ſuperintendance of the fabric of St. Peter's, the fatigue of which, however, is ſuppoſed to have contributed to his death, about 1640.

A very beautiful compoſition of Ciampelli, repreſenting the death of St. Antonio Abate, is engraved in the Etruria Pittrice. Baglione. Lanzi, Storia Pittorica. Orlandi.

CIAMPI, VINCENZO, an opera compoſer of conſiderable merit, who arrived in England in 1748, with a new company of comic ſingers brought hither from Italy by Signor Croza, for the firſt time. Theſe performers, conſiſting of Pertici, Laſchi, and Guadagni, then very young for the firſt ſerious man; Fraſi, and afterwards the Mellini, for ſerious woman; and the comic female characters by the wives of Pertici and Laſchi, the two beſt buffo actors we ever ſaw on any ſtage, formed a very good troop; and in the comic operas of "La Comedia in Comedia, Orazio, Don Calaſcione, Gli tre Ciciſbei ridicoli," &c. compoſed by Latilla, Natale Reſta, and Ciampi, who came over as maeſtro to the company, pleaſed the public, and filled the theatre, very ſucceſsfully, during the whole ſeaſon.

Ciampi remained in this country till the arrival of Cocchi in 1754, and compoſed ſeveral comic operas, as "Il Negligente," "Bertoldo," &c. and the ſerious operas of "Adriano in Siria," "Didone," and "Il Trionfo di Camilla." He likewiſe publiſhed ſix organ concertos, in which there were ſome maſterly movements; but though all ſuperior to the concertos of Filton, then in high favour, particularly in the country, being leſs familiar and common, they were never much noticed or performed in public. The productions of Ciampi ſtrike us now as they did fifty years ago: they are not without merit; he had fire and abilities, but there ſeems ſomething wanting, or redundant, in all his compoſitions; we never ſaw one that ſatisfied us, and yet there are good paſſages in many of them. "Adriano in Siria" was compoſed for ſecond-rate ſingers, and the muſic is of the ſame kind. The comic ſongs of "Il Negligente" are infinitely better than his ſerious ſongs; and convince us that the buffo ſtyle, for which he came over, was that in which nature beſt aſſiſted him.

CIAMPINI, JOHN-JUSTIN, born at Rome in 1633 was firſt engaged in the ſtudy of the law, with an intention of becoming advocate, but he afterwards attached himſelf ſolely to the practice of the apoſtolic chancery, in which he ſucceſſively occupied various poſts. He was much attached to the ſtudy of the belles lettres, which he promoted by various publications. He took a part in a literary journal commenced at Rome in 1668, and in three years he formed a ſociety for the ſtudy of eccleſiaſtical hiſtory. Under the protection of Chriſtina, then reſident at Rome, he founded, in 1677, an academy for phyſics and mathematics, which attained to conſiderable celebrity. He died in 1698, leaving behind him many works, which exhibit much learning, but they are deficient in method and purity of diction. His chief work is entitled "Vetera Monumenta, in quibus præcipue Moſaica opera, Sacrarum Profanarumque ædium Structura illuſtrantur," 2 vols. folio. This is a learned and curious treatiſe on the remains of ancient buildings and moſaics in Rome, illuſtrated with numerous engravings. The great object of this work is the elucidation of various points in eccleſiaſtical hiſtory. He was a collector of curious books, and well acquainted with their value.

CIANESUS, *Cianidzkhali*, in *Ancient Geography*, a river of Aſia in the Colchis territory. It flowed towards the W.S.W. and diſcharged itſelf into the Euxine Sea, N. of the mouth of the Phaſis.

CIANI, a denomination given by Livy to the inhabitants of the town of Cium, in Aſiatic Myſia.

CIANICA, a town of Aſia, placed by Ptolemy in the Melitene, a county of Leſſer Armenia.

CIANIS, a river which ran near the town of Cium in Aſiatic Myſia.

CIANO, in *Geography*, a town of Piedmont, in the Canaveſe; 12 miles S.E. of Jvrea.

CIANUS, SINUS, the *gulf of Cianus*, was formed by part of the waters of the Propontis, which extended towards the eaſt, between a peninſula that conſtituted northwards a portion of Bithynia, and ſouthwards part of the continent where Olympena was ſituated. It took its name from the town of Cius, ſeated at the bottom of the gulf.

CIASA, or CÆASA, an ancient town of Aſia, in Babylonia.

CIBALAS, CIBOLA, or CIVOLA, the ancient name of New Grenada, in Terra Firma, South America, and alſo of a town in this province. The country, though not mountainous, is cool; and the Indians, who inhabit it, are ſaid to be the whiteſt, moſt witty, moſt ſincere, and moſt orderly of all the aboriginal Americans. When the country was diſcovered, they had, each of them, only one wife, and were extremely jealous. They worſhipped water, and an old man that was a magician, whom they ſuppoſed to lie concealed under one of their lakes.

CIBALIS, or CIBALÆ, in *Ancient Geography*, a town of Lower Pannonia, whoſe name is ſtill preſerved in the obſcure

obscure ruins of Savilei; seated on the Save about 50 miles from Sirmium, the capital of Illyricum, and about 100 from Taurunum, or Belgrade, and the conflux of the Danube and Save. This town is famous for the first battle fought on the 8th of October, A.D. 315, between Constantine and Licinius; in which the latter, after a severe conflict, and the loss of more than 20,000 men, was obliged to retreat and make his escape, at the head of his cavalry, to collect a new army in Dacia and Thrace.

CIBAO, in *Geography*, a groupe of high mountains, occupying the centre of the island of St. Domingo; from which diverge three large chains, the longest stretching towards the east, and dividing that part of the island; another stretching to the north-west, [illegible]; and another, of less [illegible], [illegible] in the same direction, and terminating at Cape St. Mich. See St Domingo.

CIBARIA, a term which, in its general acceptation, signifies food, meat, victuals for man, cattle, fishes, &c. But in a *Military Sense* it denotes provisions, or what the French call *munitions de bouche.* Cicero says, that when a Roman army set out on a march, each soldier carried provisions with him for 15 days; and Titus Livius says for a whole month. The Greeks, who made but short campaigns, and seldom at a great distance from their own cities and territories, were not impeded in their marches and operations by great quantities of baggage or supplies, and always returned home to pass the winter.

CIBARITIS, or Cybaretis, in *Ancient Geography*, a country of Asia Minor, near the Mæander; supposed to be the territory of the town of Cibyra.

CIBBER, Colley, in *Biography*, an eminent actor and dramatic writer, was born in Southampton-street, London, on the 6th of November, 1671. His father was a statuary, a native of Holstein, who came to England about the time of the Restoration. In London are several specimens of his talents as an artist. Of these are the statues of the kings round the Royal Exchange, as far as king Charles, and that of sir Thomas Gresham in the piazza beneath. But his most capital works are the two figures of melancholy and raving madness, which were till lately in the front of Bethlehem. Colley bore the name of his mother; his first education was at the free-school at Grantham, whence his father hoped to get him elected into Winchester college, to which he had some claim, on account of his maternal descent from William of Wykeham; he was, however, disappointed. He would then willingly have sent him to the university in order that he might have been brought up to the church; but in this also his schemes were baffled. At length the young man pursued his own inclination, and, at eighteen, entered as a performer at Drury-lane theatre. His encouragement was at first small, it being several months before he was allowed ten shillings a week salary. As an actor he excited attention by performing the part of lord Touchwood in the "Double Dealer," to which he had been recommended by Mr. Congreve, who was fully satisfied with his manner of acting; and in consequence of his recommendation his salary was doubled. His father settled on him twenty pounds per annum; and being in his twenty-second year he married a lady, with whom he had some fortune. He gained considerable reputation by performing the part of Fondlewife in the "Old Bachelor:" and in 1696 he appeared as a dramatic writer, and his comedy of "Love's last Shift," or the "Fool of Fashion," was pronounced by lord Dorset, then lord chamberlain, the best first play he had ever known. He himself acted the principal character, to which his talents were well adapted. In some other productions Cibber was by no means so happy; his "Woman's Wit" was ill-received, and his "Xerxes" existed but a single night. The comedy of "Love makes a Man," though not original, proved beneficial to him; but his principal comedy was the "Careless Husband," which extorted praise from Pope, who never was the friend of Cibber, and who afterwards became his severe satirist. This comedy, which has been said to contain the most elegant dialogue, and the most perfect knowledge of persons in real life that has appeared in any language, is by no means a perfect play. It possesses scarcely any plot, and its success depends chiefly upon smart conversation, scenes, and the display of some lively and rattling characters, with which the stage at that time abounded. Its professed object is the reclaiming of a libertine husband; yet the virtuous wife is far from being properly displayed, and every superiority is given to an agreeable rake. Without enumerating the several pieces brought forward by Cibber, it is sufficient to say, that his importance as an actor continued to increase; and in 1711 he became manager and joint patentee of Drury-lane theatre; his brother managers were Wilks and Doggett. At the accession of George I. a new patent was granted; but instead of Dogget the names of Booth and Steele were inserted. The necessities of sir Richard Steele were not satisfied with the common profits, and he withdrew from the management; this led to a chancery suit, in which Cibber pleaded his own cause so successfully, that a decision was given in favour of himself and his brother managers.

In 1717, Cibber brought forward his comedy of "The Nonjuror," levelled at the Jacobite party. It had a great run, and was acted for eighteen succeeding nights: on account of its tendency, the author received two hundred pounds from the king, and the office of poet laureat. He soon after gave up his share in the theatre, and withdrew from the business of the stage, coming forward only on particular occasions, as an actor, when he had fifty guineas per night as a salary. At the age of seventy he professed himself the humble admirer of Mrs. Woffington, and was delighted to act with her in the play of the "Old Bachelor." In 1740 Cibber published an apology for his life, which included an historical view of the stage during his own time. The ease and sprightliness with which this was written, together with the numerous anecdotes which it contains, rendered it a very popular work, and its reputation is supported to the present time. In 1745, when he was turned of seventy-four, he appeared in the character of Pandulph, the pope's legate, in his own tragedy, entitled "Papal Tyranny in the Reign of King John;" and notwithstanding his advanced years, performed the part with great spirit and vigour. In 1747 he published "Remarks on Middleton's Life of Cicero," a work to which it will be generally admitted he was by no means competent; it was of course short-lived, and is now almost wholly forgotten. Cibber finished a long and active life on Dec. 12, 1757. His man-servant, with whom he had conversed, in apparently good health, at six in the morning, found him dead at nine, lying on his pillow, just as he had left him. He had entered his eighty-seventh year. He left two children. Theophilus adopted his father's professions of actor and dramatic writer, but with very inferior success. He was a mean and depraved character, and finished a life of distress and infamy by shipwreck in his passage to Ireland, in 1758. His daughter, Mrs. Clarke, was also on the stage, which was one only of the many parts she acted in life, and few women ever passed through a greater variety of adventures and occupations. When she quitted the theatre she kept a shop in Long-acre; then became mistress of a puppet-show; afterwards in man's cloaths she ap-

peared

peared as a valet to a nobleman: ſhe was afterwards a ſort of pork-butcher; and nine years of her life were ſpent in the occupation of a ſtrolling-player in the country. In Wales ſhe was a farmer and a paſtry-cook; at Briſtol the corrector of the preſs for a printer. She at length found means to take a public-houſe at Iſlington, where ſhe died in great diſtreſs in 1760. To return, however, to Cibber; he was a man of great vivacity, good-humour, and benevolence; his chief failing was vanity, the preponderance of which, and the liberties which he took with the characters of other perſons, without any ill-intention, produced him many enemies, by whom, and by Pope in his "Dunciad," in particular, he was attacked with much more ſeverity than he deſerved. Their attacks, though often very pointed and malignant, made but little impreſſion upon him, and he was even ready to acknowledge his foibles with frankneſs. As an actor he poſſeſſed great merit; but his judgment as a manager was not always to be depended upon: his behaviour to young authors was not always candid, and ſometimes inſolent and overbearing. His own pieces are generally of a moral tendency, and his comedies are entitled to praiſe. He collected and publiſhed his pieces in two volumes 4to. and they have ſince been re-publiſhed in five volumes 12mo. Biog. Brit.

Cibber, Mrs. Susannah Maria, the ſiſter of Dr. Arne, has been juſtly celebrated as a great tragic actreſs; but as ſhe firſt appeared on the ſtage as a ſinger, in her brother's opera of Roſamond, written by Addiſon, and afterwards ſung in Handel's oratorios of Sampſon and the Meſſiah, the firſt time they were performed, both in England and Ireland, and for whom he compoſed his two beſt oratorio airs: "Return, O God of Hoſts," and "He was Deſpiſed and Rejected;" which, with a feeble voice, and little knowledge of muſic, by a natural pathos, ſhe ſung in a more affecting manner, than much finer ſingers have ever done; theſe conſiderations, and perhaps, the ſtimulus of friendſhip, incline us to give her an article here, for her vocal powers. As an actreſs, ſhe was thought moſt excellent in tender parts, till, during the rebellion, ſhe appeared in the character of Conſtance in Shakeſpear's King John, in which ſhe manifeſted not only the maternal tenderneſs of a Merope, but ſuch dignity, ſpirit, and paſſion, as perhaps, have never been exceeded, if equalled, on any ſtage. Handel himſelf was exceedingly partial to her, and took the trouble of teaching her the parts expreſsly compoſed for her limited compaſs of voice, which was a mezzo ſoprano, almoſt, indeed, a contralto, of only ſix or ſeven notes, with all the drudgery of repetition neceſſary to undergo, in teaching perſons more by the ear than the eye. He and Quin uſually ſpent their Sunday evenings at Mrs. Cibber's, where wit and humour were more frequently of the party, than Melpomene, Euterpe, or Orpheus.

With reſpect to the effect of Mrs. Cibber's ſimple, but pathetic, ſtyle of ſinging, it ſeems to demonſtrate, that expreſſion in muſic is the ſoul, and mere ſounds the corporeal part. The moſt beautiful and affecting air of an oratorio or ſerious opera, if ſung without expreſſion, becomes a vapid and unintereſting pſalmody: *notes et rien que des notes*, as Rouſſeau ſays, notes and nothing but notes. But this expreſſion muſt be ſuited to the language in which the air is ſet. The ſongs which Handel expreſsly compoſed for Mrs. Cibber's limited powers, were never half ſo touching when ſung by a Monticelli, a Guarducci, or a Guadagni, great ſingers as they were, as by our countrywoman, though, comparatively, ignorant of muſic, and poſſeſſing but a thread of a voice. However, from the excellence of her underſtanding, knowledge of our language, and the natural pathos in the tone of her voice, ſhe never failed to penetrate into the inmoſt receſſes of the ſoul of every hearer of feeling in ſinging theſe airs, as much as ever ſhe did in the moſt tender and diſtreſsful ſcenes of declamation.

CIBDELOPLACIA, in *Natural Hiſtory*, the name of a genus of ſpars. The word is derived from κίβδηλος, *impure*, and πλὰξ, *a cruſt*. The bodies of this genus are terrene ſpars, that is, are compoſed of ſpar, debaſed by a very large admixture of earth, and are not, therefore, of the leaſt brightneſs or tranſparence; and are found formed into thin cruſts, coating over vegetable and other extraneous bodies in form of incruſtations. Of this genus there are five known ſpecies, ſome of them uſed in medicine, and diſtinguiſhed by particular names.

CIBDELOSTRACIA, the name of a genus of ſpars. The word is derived from κίβδηλος, *fouled* or *adulterated with extraneous matter*, and ὄστρακον, *a cruſt* or *ſhell*.

The bodies of this genus are cruſtaceous ſpars, ſo highly debaſed with earth, that they appear to the naked eye mere earths; they are deſtitute of all brightneſs or tranſparence, and are formed into thin plates, and uſually found incruſting over the ſides of fiſſures of ſtone. Of this genus there are ſeven known ſpecies.

CIBELIANA, *in Ancient Geography*, an epiſcopal ſee and town of Africa.

CIBERIS, a town of the Thracian Cherſoneſus, which was re-built and re-peopled by Juſtinian, after having been ruined; and in which he conſtructed baths, hoſpitals, and other edifices.

CIBILITANI, a people placed by Pliny in Luſitania.

CIBORIA, in *Antiquity*, the large huſks of Egyptian beans, which are ſaid to have been ſo large as to ſerve for drinking cups; whence they had their name, *ciborium* ſignifying *cup* in the Egyptian language.

CIBORIUM, in *Eccleſiaſtical Antiquity*, the covering for the altar of a church being an inſulated edifice, conſiſting of four columns ſupporting a dome.

This name was originally given to the huſks of Egyptian beans (ſee the preceding article), and thence by an eaſy tranſition came to denote a dome of the ſame form. The ciborium was in general uſe during the lower and middle ages, but was at length ſupplanted by the baldaquin, an object of the ſame nature, but in the form of a canopy. The application of a ciborium was not ſtrictly confined to the covering of an altar, they were alſo erected over the tombs of ſaints or martyrs, and the Italians call any inſulated tabernacle ciborio; thus there were ſometimes ſeveral in a cathedral, but in general there was only one placed over the great altar, and the ſpace which it occupied was called the ſanctum-ſanctorum.

The moſt magnificent ciborium ever known was that erected by Juſtinian in the church of St. Sophia at Conſtantinople. Four large columns, of a fine red marble, ſupported a ſilver dome, on the ſummit of which was placed a globe of maſſy gold, which weighed 118 pounds; lilies of gold ſurrounded the globe, and fell in feſtoons; they weighed 116 pounds, and in the middle was placed a croſs of 75 pounds, of the ſame metal, and covered with the moſt rare and precious jewels.

CIBOTUS, in *Ancient Geography*, a name given by Strabo to a port which had been formed near the town of Alexandria in Egypt.

CIBOULS, or Chibouls, in *Botany*, the Welſh onion. See Allium *fiſtuloſum*.

CIBSAIM, in *Ancient Geography*, a town of Judæa, in the tribe of Ephraim. It was given to the Levites of this tribe, who belonged to the family of Caath, the firſt of the Levites;

Levites; and is mentioned in the book of Joshua and the first book of Chronicles.

CIBULON, in *Geography*, a town of Asia, in the country of Tibet; 8 miles N.E. of Zuenga.

CIBUS Castrensis, the food or nourishment which the Roman soldiers took in their camps, which consisted chiefly of bread, bacon, vegetables, and cheese. Their drink or beverage was a sort of oxicrat, or a mixture of water and vinegar. They were not permitted to go to their meals without a signal or order for the same.

Cibus *ferialis*, in *Antiquity*, an entertainment peculiar to a funeral; for which purpose, beans, parsley, lettuce, bread, eggs, lentils, and salt were in use.

CIBYRA, in *Ancient Geography*, called the *Great*, a town of Asia Minor, situated on the confines of Phrygia, Caria, Lycia, and Pisidia. It is called *Cibyrrha* by Ptolemy. This town was watered by a river which, according to Pliny (l. v. c. 28), descended from the mountains called "Cibyratarum Juga," and after passing through the territory of Cibyra, discharged itself into the river Calbis. Cibyra, as Strabo informs us (l. xiii.), was an ancient colony of Lydians, who took possession of Cabatia, a country in the vicinity of Lycia; and in process of time, the Pisidians removed this town to a more advantageous situation, and built a new town, 100 stadia in circuit. The inhabitants, who were very numerous, spoke four different languages, viz. the Lydian, Pisidian, Lycian, and Greek. The town, situated in a fertile district, acquired great celebrity by the excellence of its laws and the mildness of its government, and thus attained to a very high degree of prosperity. The dominions of this town extended from Pisidia and Milyuda to Lycia, and the coast over against the isle of Rhodes, and they were able to raise 30,000 foot and 2000 horse. When the consul Cneius Manlius was commissioned, in the year of Rome 565, to reduce the Galatæ in Asia Minor, he passed near Cibyra, and obtained from Moagetes, the governor of this town, 100 talents in silver, and 10,000 measures of corn, who thus prevented the pillage of the country, and the threatened siege of the capital. Polybius says, this town was subjugated by the prætor L. Muræna, and its territory reduced to a province, in the year of Rome 671. Cibyra maintained its dignity and splendour under the Roman government, and became the capital of an extensive department, which contained 25 towns, and which Pliny (l. v. c. 25.) calls "Conventus Cibyraticus." This department remained, for several years, a part of the government of Cilicia. At the commencement of the civil war between Cæsar and Pompey, the departments of Cibyra, Pisidia, and Lycia, were detached from the province of Cilicia, and annexed to that of Asia. Tacitus (Annal. l. iv. c. 17.) reports, that Cibyra had sustained considerable damage by an earthquake; and Tiberius issued a decree of the senate, that it should not pay tribute for three years. This epocha was the year of Rome 776. Accordingly this emperor was considered by the inhabitants as the founder of their city, and in order to perpetuate the remembrance of it, they caused the series of years, inscribed in their annals and engraved on their monuments, to be reckoned from the epocha of the revival of their city. Cibyra took a distinguished part in the public rejoicings occasioned by the victories of Gordian; it offered solemn sacrifices and celebrated public games, as may be seen on an urn, which was engraved on a medal struck in honour of Gordian, in the year 289 of his æra, or 242 of Christ. Strabo speaks in terms of high commendation of the vines that grew in the vicinity of this place, and of the excellent wines which they afforded; and he adds, that Cibyra derived a large revenue from its iron mines, and that its inhabitants carried on a considerable commerce in hams. Apollo had a temple at Cibyra, and Mars was probably its principal and tutelary divinity, represented on its public monuments. Cibyra was at first governed by its own princes, but after it became subject to the Romans, by a senate under a chief magistrate. About the year 705 of Rome, Cibyra obtained from the Romans the privilege of being governed by its own laws and by its own magistrates, whose names appear on the ancient medals. It had also the privilege of coining money, which it retained for many ages under the Roman emperors. It further obtained from the emperors and the senate, the honour of placing on its monuments the title of Cæsarea, probably in honour of Tiberius, its restorer, adopted by Augustus into the family of the Cæsars. After the proconsular province of Asia was divided into several parts by Dioclesian, the town of Cibyra was comprehended within the province of Caria. Upon the division of Constantine the Great, Cibyra was referred to the department of the Thracesians and of Anatolia. In the first ages of the church, the city of Cibyra was erected into an episcopal see in the ecclesiastical province of Caria, under the metropolis of Aphrodisias.

Cibyra, a town of Asia Minor, in Pamphylia. It was situated in the interior of the country, S.E. of Aspendus. Its territory extended along the sea-coast, between the valley of Sidé and the river Melas, according to Strabo, l. xiv. Ptolemy places it in Cilicia Trachæa.

CIBYRATICA, one of the principal governments of Asia Minor, the capital of which was Cibyra of Phrygia.

CICACOLE, a circar of Hindoostan, on the N.W. coast of the bay of Bengal; 150 miles long, and from 15 to 30 broad.—Also, a town in this circar; 150 miles N.E. of Rajamundry, and 308 E. of Hydrabad. N. lat. 18° 16′. E. long. 84° 8′.

CICADA, in *Entomology*, a genus of the hemipterous order, possessing, according to the Linnæan arrangement, the following characters. Antennæ inflected, or bent, inwards under the breast; antennæ setaceous; the four wings membranaceous and deflected; legs in most formed for leaping, or as in the maniferæ for walking or creeping.

Linnæus, in order to comprehend the various natural tribes, or families, of insects, which he includes under the general head of cicada, found it necessary to distribute them into several distinct sections, some of which, in the entomological arrangements of more modern writers, constitute, and with much propriety, so many different genera. The *foliaceæ* family of the Linnæan cicadæ, consist of those in which the thorax is compressed, membranaceous, and larger than the body. The *cruciatæ*, those which have the thorax armed on each side with a horn or spine. The *maniferæ*, those which have the feet formed for creeping or walking instead of leaping. The *ranatræ*, those having the posterior feet formed for leaping. And the *deflexæ*, those whose wings are wrapped round the sides of the body.

Scopoli divides the cicadæ into three different sections, according to the substance and texture of the wing-cases; the first containing those cicadæ which have the whole of the wing-cases coriaceous; the second, those coriaceous from the base to the extent of half their length; and the third, such as have those parts entirely membranaceous.

In the Fabrician system of entomology, the Linnæan cicadæ are divided into several genera; in one of the latest and most comprehensive works of that author, his "Entomologia Systematica," they are divided into four genera, membracis, tettigonia, cicada, and cercopis, and this final arrangement is retained in his "Supplementum," published since, with this difference only, that his former genus, cicada, is divided into two genera,

genera, one of which he names flata, and the other cicada, as before. A new genus, delphex, comprehending two of Panzer's species of cicada, is likewise added, so that Fabricius may be considered as having constituted six distinct genera of those insects, which Linnæus would have united in his single genus cicada. Gmelin has endeavoured to reconcile the Linnæan and Fabrician arrangements, by making the genera of the latter subservient to the sections of Linnæus: the last Fabrician genera were, however, unknown to Gmelin.

The cicadæ live on various kinds of plants; the larvæ are entirely destitute of wings, which in the pupa begin to appear; but both in the larva and pupa state, they resemble the perfect insect, except in being destitute of wings. The larvæ, especially those of the Linnæan family ranatræ, discharge a kind of froth from the vent and pores of the body, under which they conceal themselves; they are furnished with six feet, and are very active. The males of the perfect insect, in general, chirp like the cricket; and some of the larger kinds of the tettigonia family possess two peculiar drum-like organs, which emit a loud and incessant noise at the pleasure of the insect, as is particularly exemplified in some of the Chinese and North American cicadæ. (See Donov. Inf. China, cicada atrata, &c.)

The following species of this extensive genus are described by Linnæus, Scopoli, Geoffroy, Fabricius, Donovan, and others.

Inflata. Thorax foliaceous; the membrane inflated, testaceous and reticulated. *Membracis inflata*, Fabr. A native of Cayenne.

The membrane of the thorax is large, inflated; on each side seven black dots; body yellowish; wing-cases hyaline, and dusky on the thinner margin.

Rhombea. Foliaceous, the membrane rhombic and broader behind. *Cicada rhombea*, Linn. Phil. Tranf. A.D. 1765. Inhabits South America.

Foliata. Thorax foliaceous, rounded, yellow, with a black band and spot. *Cicada foliata*, Linn. *Membracis foliata*, Fabr. A native of South America.

Lunata. Thorax foliaceous, rounded, black; with three white lunules. *Membracis lunata*, Fabr. From Cayenne; cabinet of V. Rohr.

Fasciata. Thorax foliaceous, rounded, and black, with two bands, the anterior one fulvous, posterior white. *Membracis fasciata*, Fabr. Inhabits Cayenne. Same country as the last.

Bracteata. Thorax foliaceous, green, and immaculate. *Membracis bracteata*, Fabr. An insect of small size, from the same country as the preceding.

Squamigera. Thorax foliaceous, acute before and behind, and grey. Linn. Inhabits South America.

Hastata. Horn of the thorax projecting above the head, compressed, and carinated; body grey. *Membracis hastata*, Fabr. A native of South America; size small.

Lanceolata. Horn of the thorax projecting above the head, and incurvated; body black, with two white dorsal spots. *Membracis lanceolata*, Fabr. Inhabits Cayenne.

2-Maculata. Horn of the thorax compressed, extending beyond the head; brown, with a yellow marginal spot each side. *Membracis 2-maculata*, Fabr. *Cicada 2-pustulata*, Gmel. Inhabits America. Described from the cabinet of Bosc.

Spinosa. Thorax three-horned, and produced behind to the length of the wings. Fabr. Inhabits India.

Acuminata. Thorax three-horned; the middle horn longest and compressed. Fabr. Inhabits Pennsylvania. Banksian cabinet.

Planata. Thorax flat, produced each side, and acute; body greenish. Fabr. Inhabits the East Indies.

Aurita. Thorax two-eared; shield of the head dilated and rounded anteriorly. *Cicada aurita*, Linn. Found in Europe.

Flexuosa. Thorax two-horned, and blue: horns depressed and black. *Membracis flexuosa*, Fabr. A native of the East Indies.

Marginata. Thorax two-horned, and longer behind than the abdomen; margin yellowish. *Membracis marginata*, Fabr. Inhabits China.

Horrida. Thorax two-horned, produced behind, with two large tubercles, and the tip three-spined. *Membracis horrida*, Fabr. Inhabits Cayenne.

Trifida. Thorax four-horned, hairy, produced and trifid behind; the divisions subulate. *Membracis trifida*, Fabr. A native of Cayenne.

Punctata. Thorax two-horned, spotted with white, and lengthened behind, beyond the abdomen. *Membracis punctata*, Fabr. Described from the Banksian cabinet. Inhabits Brasil.

Cornuta. Thorax two-horned, black; behind subulate, and as long as the abdomen; wings fuscous. *Cicada cornuta*, Linn. An European species. Donov. Brit. Inf.

Bubalus. Thorax two-horned, and long as the thorax behind; abdomen greenish; head and abdomen fulvous; wings hyaline. *Membracis bubalus*, Fabr. Inhabits North America. Helwig.

Taurus. Thorax two-horned, fuscous, filiform behind, and as long as the abdomen; horns arched. *Membracis taurus*, Fabr. Inhabits the East Indies. Koenig.

Vitulus. Thorax two-horned and green, with a white curve and line; posterior part produced as long as the abdomen; wings white. *Membracis vitulus*, Fabr. Inhabits America.

2-Punctata. Thorax nearly unarmed, produced behind, and shorter than the abdomen; wing-cases with a black spot at the base. *Membracis 2-punctata*, Fabr. A native of New Holland. *Cicada binotata*, Gmel.

Bonasia. Thorax two-horned, and lengthened behind, with white margin; at the base of the wings a white spot. *Membrasis bonasia*, Fabr. An American species described from the Hunterian Collection.

Convoluta. Thorax unarmed, greenish, with yellow margin, and length of the abdomen behind. *Membracis convoluta*, Fabr. Inhabits Brasil. Banksian Cabinet.

Mutica. Thorax unarmed, ferruginous, carinated, and length of the abdomen behind. *Membracis mutica*, Fabr. A native of North America.

Inermis. Thorax unarmed, greenish, length of the abdomen behind, and subulate. *Membracis inermis*, Fabr. Same country as the preceding.

Genistæ. Thorax unarmed, fuscous, and half the length of the thorax behind. Fabr. Inhabits France, Geoffroy; and England, Lee.

Sinuata. Thorax foliaceous; back in the middle broad, emarginate; body brown. *Membracis sinuata*, Fabr. An American species.

Emarginata. Thorax foliaceous; back broad, emarginate; body black, with a few whitish streaks; legs white. *Membracis emarginata*, Fabr. Inhabits Carolina. Bosc.

Fuscata. Thorax foliaceous, rounded, and fuscous, with a narrow white streak anteriorly, and a broad white band behind. *Membracis fuscata*, Fabr.

Inhabits the East Indies. The wings are fuscous, and the tip of the thorax sharp-pointed and black.

Rupicapra. Thorax three-horned; the middle one somewhat longer, and recurved wing-cases dusky hyaline. *Membracis rupicapra*, Fabr.

Inhabits India, Daldorff. This is small, general colour fuscous; the lateral thoracic horns thickest, obtuse, and somewhat dentated; wings white.

Tarandus. Thorax two-horned; horns arched; wing-cases hyaline. *Membracis*, Fabr. Inhabits the East Indies. In size and appearance this resembles *cicada cornuta*. The body is dusky, on the back fuscous; the horns on the thorax are compressed and vaulted; thorax subulate, and lengthened behind; wing-cases hyaline, veined with fuscous; wings whitish; legs ferruginous.

Capra. Thorax two-horned, short behind, and emarginate; body fuscous. *Membracis capra*, Fabr. Inhabits India.

Minuta. Thorax nearly unarmed, scabrous, and length of the abdomen behind; wing-cases whitish, at the base black. *Membracis minuta*, Fabr. A very small species is found in the East Indies.

Fasciata. Thorax nearly unarmed, behind as long as the abdomen; wing-cases dusky, with a yellow band at the base. *Membracis fasciata*, Fabr. Inhabits American islands. Bosc.

Obs. This, and the seven preceding insects, are new species, described in the Supp. Ent. Syst. of Fabricius.

* Section *Mannifera*, (legs not formed for leaping) Linn. Genus *Tettigonia*, Fabr.

Indica. Black; thorax with a yellow stripe, and towards the extremity of the abdomen an orange band; wing-cases brownish olive, with red veins. Donov. Inf. India.

A new species, and unquestionably the most striking and magnificent insect of the genus hitherto described. A single specimen only was discovered in Bengal about seven or eight years ago, and which is now deposited in the Imperial Cabinet at Vienna. The description and figure in Donov. Insects of India is taken from that individual and unique specimen.

Grossa. Thorax green, with a few black lines; wings white, with a yellow spot at the base of the posterior ones, Fabr. Inhabits Brasil. Banksian Cabinet.

Fasciata. Head and thorax black, spotted with rufous; wing cases black, with an abbreviated white band, Fabr. A large species, and inhabits Java. *Cicada javana* of Gmelin.

Grisea. Grey; wing-cases pellucid as water; posterior margin dotted with black; rib white on the anterior part. Fabr. A native of America.

Limbata. Thorax dilated at the margin, and acute; lower wings black, with white posterior margin. Fabr. An American species in the Banksian Cabinet.

Dilatata. Thorax dilated at the margin, and black; wings whitish. Fabr. Found in Jamaica.

Spinosa. Thorax armed each side with a single spine, and fuscous; wing cases dusky, with a macular black streak. Fabr. Inhabits Sumatra.

Vaginata. Testaceous; wing-cases whitish, with a black rib. Fabr. Same country as the last.

Tibicen. Scutel emarginate; wings with a greenish rib. *Cicada tibicen*, Merian. Linn. Inhabits South America.

Septendecim. Black; wing-cases white, with a yellow rib. Linn. Inhabits America.

Variegata. Black; thorax variegated with testaceous; wing-cases hyaline, with two black spots. Fabr. A native of Carolina.

Catena. Thorax variegated; wing-cases hyaline, with punctured nerves on the anterior part, and two undulated fuscous streaks behind. Fabr. Inhabits the Cape of Good Hope.

Maculata. Black; thorax, wing-cases, and wings, spotted with yellow. Drury. Inf. A native of China.

Cantans. Head and thorax black; wings at the base white. Fabr. A native of Barbary. Desfontaines.

Æstuans. Black; two spots on the thorax, and side of the abdomen beneath pale. Fabr. Same country as the preceding.

Pustulata. Black; head and thorax spotted with red; upper wings with darker bands at the base; veins testaceous. Fabr. A large species, and inhabits South America.

Stridula. Villous; wing-cases greyish; wings yellow, with the margins hyaline. Linn. &c. *Cicada catena*, Drury. *Cicada capensis* of Linnæus is supposed to be a variety only of his *Cicada stridula*.

Cingulata. Thorax spotted; wing-cases hyaline; rib and spot fuscous; abdomen black, with yellow bands. Fabr. Inhabits New Zealand. Described from a specimen in the Banksian Cabinet.

Villosa. Thorax fuscous and green, varied; breast white and villose. Fabr. A native of the Cape of Good Hope.

Cruentata. Thorax variegated; wing-cases hyaline; rib yellowish; abdomen black, with sanguineous bands. Fabr. A native of New Zealand.

Conspurcata. Black; wing-cases spotted with yellow at the base; tail yellow. Fabr. Inhabits India.

Hæmatodes. Black; incisures of the abdomen, and nerves of the wings sanguineous. Linn. A native of the south of Europe.

Plebeja. Scutel bidentated at the tip; wing-cases with four anastomoses, and six ferruginous lines. Linn.

Inhabits Africa and Italy, and is presumed to be, with the next species, the cicada of the Greek and Roman poets. See Notes on *Cicada atrata*. Donov. Inf. China.

Orni. Wing-cases with six concatenate dots within the margin, and the inner anastomoses brown. Linn. Inhabits the same country as *Cicada plebeja*.

Repanda. Wing-cases with a flexuous line; margin of the wings hyaline. Linn. A native of India.

Reticulata. Grey, with a white line on the thorax; wing-cases reticulated with white.

Kæmpferi. Wing-cases fuscous, with hyaline bands; wings black, with the margin hyaline. Fabr. Sent by Kæmpfer from Japan and preserved in the British Museum.

Picta. Thorax black, with testaceous spots; wing-cases veined, with white at the base; rib black. Fabr. Inhabits Provence. Bosc.

Atrata. Black; wings white, at the base black; veins testaceous. Fabr. Donov. Inf. China.

Australasiæ. Testaceous; margin of the thorax dilated; wings hyaline. Donov. Inf. New Holland.

A new species, of considerable size; the general colour testaceous.

Testacea. Black; abdomen sanguineous; wing-cases and the wings testaceous, veined with black. Stoll. Inhabits Tranquebar.

Flavescens. Yellowish-green; posterior shanks armed with a single tooth. Fabr. Inhabits Guinea. Ifert.

Olivacea. Olivaceous; head pale, with a transverse black spot on the snout, and another on the crown; posterior shanks armed with a single tooth. Fabr. A small species, and like the former, inhabits Guinea.

Sangui-

Sanguinolenta. Black; mouth, two ſpots on the thorax, and abdomen ſanguineous. Drury, Donov. Inſ. China, &c.

Splendidula. Wing-caſes golden-fuſcous; anterior ſhanks thick, dentated, and rufous. Fabr. Donov. Inſ. China.

Ephemera. Wing-caſes hyaline, with fuſcous ſpots. Stoll. Inhabits Surinam.

Muta. Wing-caſes hyaline; rib ſanguineous; abdomen with a ſanguineous dorſal line. A ſmall ſpecies, deſcribed by Fabricius from a New Zealand inſect in the Bankſian Cabinet.

Violacea. Violet; wings fuſcous at the tip. Linn. Muſ. Lud. Ulr.

Minuta. Livid; dorſal line on the thorax, and nerves of the wing-caſes yellowiſh.

8-Guttata. Thorax behind black, with a large, trifurcated, teſtaceous ſpot; wing-caſes black, with four white ſpots on each. *Tettigonia 8-guttata.* Fabr.

Inhabits Cayenne. This and the following tettigoniæ are new ſpecies deſcribed in the Fabrician Supp. Ent. Syſt.

Costalis. Black; wing-caſes hyaline, with a fulvous rib. Inhabits Philadelphia. Boſc.

Punctata. Thorax black behind, with three ferruginous lines; wing-caſes hyaline, with a white ſtigma, and two ſtreaks of fuſcous dots. A native of Ruſſia. An inſect of moderate ſize.

Hyalina. Black; thorax with a ferruginous ſtreak in the middle, and two ferruginous little lines; wing-caſes hyaline; ſtigma black. Inhabits the ſame country as the laſt, but is ſmaller.

Brunnea, Brown; anterior part of the thoracic lobe with three yellow ſpots on each ſide; wings hyaline.

Inhabits the iſle of France. The head is black, deepeſt in front; thorax duſky brown; ſcutel yellow; abdomen brown with the margin of the ſegments yellow.

* *Cicada,* Linn.

Genus *Flata,* Fabr. Suppl. Ent.

Perspicillata. Black; wings with an ocellated white hyaline ſpot; abdomen yellow at the tip. Fabr. An Indian ſpecies.

Ocellata. Wing-caſes compreſſed, aſcending, green, with ocellar ferruginous dots. Fabr. Inhabits Tranquebar. Koenig.

Limbata. Wing-caſes deflected, green, with red margin, the inner baſe dotted with black. Fabr. *Cicada æquinoctialis,* Gmel. An African inſect.

Candida. Snowy; wing-caſes deflected, with two ſmall yellow lines. Fabr. Suppl. A large ſpecies from the Iſle of France. Cabinet of Billardiere.

Fuscata. Wing-caſes deflected, black, hyaline and immaculate. Fabr. Inhabits Tranquebar. Lund.

Phalænoides. Whitiſh; wings deflected, patulous; anterior part of the wing-caſes dotted with black. Linn. Found on plants in America.

Bipunctata. Whitiſh; wing-caſes deflected; thorax with two impreſſed dots on the anterior margin. Linn. Same country as the preceding.

Retusa. Whitiſh, and immaculate; head retuſe. Fabr. A native of Cayenne.

Grisea. Grey; wing-caſes deflected; a black dot on the tip of the head. Fabr. A native of America.

3-Punctata. Wings deflected, green, with three whitiſh dots. Fabr. An African ſpecies.

Viridа. Green; wing-caſes deflected; wings white; front conic. Fabr. Inhabits American iſlands.

Minuta. Wings deflected, green; back ſcabrous; poſterior margin of the head, and dorſal line on the thorax ſanguineous. Fabr. Deſcribed a New Holland inſect in the Bankſian Cabinet.

Marginata. Yellow; wing-caſes deflected, and duſky; lateral line yellow. Linn. Inhabits American iſlands.

Pygmæa. Wing-caſes deflected, and immaculate; body yellowiſh. Fabr. Inhabits South American iſlands.

4-Punctata. Wing-caſes deflected, grey, with a pair of black dots on each. Fabr. &c. Same country as the laſt.

Viridana. Green; wing-caſes deflected, with two white ſpots near the baſe, and two pale bands towards the apex; wings white. Donov.

This, with the two following inſects, are new ſpecies of the Fabrician genus *flata;* natives of Botany, and deſcribed in Donovan's Hiſtory of the Inſects of New Holland.

Modesta. Pale; wing-caſes deflected, with two orange ſpots at the baſe, the inner one marked on the ſide with a black dot. Donov.

Pustulata. Whitiſh-green; wing-caſes deflected, with numerous red ſpots; poſterior angle pointed, and brown. Donov.

* Section *Cicada,* Linn.

Genus *Cicada,* Fabr. Ent. Syſt.

Cunicularia. Wings deflected, hyaline; with a ſtreak, band, and dots of brown; tail woolly. Linn. A native of India.

Lanata. Wing-caſes black, with blue dots; front red at the ſides; tail woolly. Linn. Inhabits India and China. Donov. Inſ. China.

Tomentosa. Wing-caſes deflected, green, with two interrupted fulvous bands; wings ſnowy-white, with two black bands. Fabr. Inhabits the Eaſt Indies. Muſ. Tottianum.

Barbata. Fuſcous; abdomen greeniſh; tail covered with ſnowy wool. Fabr. Deſcribed from a New Holland inſect in the Bankſian Cabinet.

Atrata. Black; thorax with four grey ſpots; margin of the abdomen yellow, with ſnowy ſpots. Fabr. A native of Cayenne.

Striatula. Above rufous, with black ſpots, beneath yellowiſh. Fabr. Inhabits Cayenne. Boſc.

Nigripennis. Black; margin of the head and thorax yellowiſh, with black dots. Fabr. Country unknown.

Ferruginea. Head, thorax, and ſcutel dotted with black; wing-caſes rufous; wings white. Inhabits the Cape of Good Hope, Fabr. Bankſian Cabinet.

Undata. Head and thorax cinereous, teſtaceous, and black, varied; wing-caſes duſky rufous, with a greeniſh lateral ſpot, and hyaline tip. Fabr. Inhabits Carolina.

Irrorata. Fuſcous; wing-caſes with the rib, baſe, and ſpeckling fulvous. Fabr. Inhabits Carolina.

Obtusa. Black; wing-caſes cinereous, hyaline at the tip. Fabr. Inhabits Cayenne.

Aurulenta. Head and thorax rufous; wing-caſes fuſcous, with cinereous tip. Fabr. Same country as the laſt.

Myopa. Head and thorax golden fuſcous, varied with black; wing-caſes hyaline, with a duſky tip, and a gold ſpot. Fabr. This alſo inhabits Cayenne.

Villosa. Green; wing-caſes deflected, whitiſh; tail woolly. Fabr. A native of South America. *Cicada Rohrii.* Gmel.

Elongata. Thorax red, with yellow lines; wing-caſes

 very

very long, and dotted with black. Fabr. Inhabits New Holland.

Histrio. Linear, flesh-coloured, with black lines. Fab. Muf. Lund. Country unknown.

Suturalis. Linear, testaceous; head with two elevated black dots, and future of the wing-cases fuscous. Fabr. Country unknown.

Nigripes. Blackish; wing-cases fuscous; nerves white, with black dots. Fabr. Inhabits Brasil.

Vittata. Yellow; wing-cases with a double longitudinal repandate and dentated ferruginous stripe. Linn. Inhabits gardens in Europe.

Lateralis. Black; wing-cases white at the sides. Linn. Panzer. Inhabits Europe.

Variegata. Above black; scutel, two yellow spots on the back, and exterior margin of the wing cases yellowish, Fabr. From the Banksian Cabinet. A native of Brasil.

Fenestrata. Above black; head and scutel yellow; margin of the wing-cases hyaline. Fabr. Inhabits the Pacific Ocean.

Flavipes. Black; head and legs yellow; wing-cases hyaline at the tip, and striated with black. Fabr. Found in Rotterdam Island.

Interrupta. Wing-cases yellow, with a double black, interrupted, longitudinal line. Linn. An European species.

Lineata. Pale; head and thorax dotted with black; wing-cases lineated with black. Fabr. Inhabits Saxony. *Cicada lyneri*, Gmel.

Acuminata. Black; wing-cases fuscous, striated, and barred with white. Fabr. *Cicada acuminalis*, Gmel. Inhabits Germany.

Abbreviata. Yellowish; wing-cases cinereous, with a black abbreviated stripe. Fabr. Inhabits Europe.

Flavicollis. Black; posterior margin of the head with the thorax yellow. Linn. Found on grass in Europe.

Viridis. Wing-cases green; head yellow, with black dots. Linn. Fn. Suec. Inhabits Europe, and is found in England. Donov. Brit. Inf.

Læta. Above black and polished, with bluish dots. Fabr. Inhabits Cayenne.

Atomaria. Golden; wing-cases obsoletely speckled with white. A native of Italy. Fabr.

Prasina. Green; wing-cases white, and hyaline at the tip. Fabr. Inhabits Italy.

Argentata. Head yellow, with black band between the eyes; thorax and wing-cases silvery, striated with fuscous. Fabr. Inhabits France.

4-Guttata. Wing-cases reddish, with two green spots and hyaline tip. Fabr. A South American insect.

Marginella. Black; head, thorax, and wing-cases edged with scarlet. Fabr. Same country as the last.

Lanio. Green; head and thorax flesh-colour. Linn. Panzer. An European insect.

Striata. Yellowish, polished; head, thorax, and wing-cases striated with white. Fabr. Inhabits France.

Ignita. Greenish, polished; head, scutel, and abdomen fulvous. Fabr. Inhabits Cayenne.

Festiva. Yellow; head and thorax with two black dots; wing-cases with three black spots. Fabr. A native of Germany.

Mixta. Yellow, variegated with black; wings black. Fabr. Inhabits Paris. Bosc.

Bicolor. Above yellow, beneath black; wing-cases pale, fuscous at the tip. Fabr. A small insect found in Denmark. *Cicada bicolorata*, Gmel.

Turca. Black; abdomen yellow; wings fuscous at the tip, with a hyaline lunule. Fabr. Inhabits South America.

Matura. Black; breast and abdomen sanguineous. Fabr. Donov. Inf. New Holland. Inhabits New Holland. Described from the Banksian Cabinet.

Nebulosa. Black; wing-cases hyaline, with the base fuscous. Fabr. An African insect. Same country as the former.

Hyalina. Fuscous; wing-cases with an abbreviated band; and posterior margin hyaline. Fabr. A native of the East Indies.

Pellucida. Grey; with a hyaline stripe in the middle of the wing-cases. Fabr. Donov. Inf. New Holland.

Cynosbatis. Fuscous; wing white and hyaline, with a margin of fuscous dots. Fabr.

Clavicornis. Fuscous; wing-cases hyaline, with a fuscous streak behind; antennæ compressed, and margined. Fabr. A native of France.

Serratulæ. Yellow; wing-cases white, with a dot, and two bands of black. Fabr. Found on thistles in England.

Nervosa. Wings fuscous hyaline; nerves white, dotted with black. Linn. Fn. Suec. Inhabits Europe.

Varia. Black, varied with green; wings hyaline, with three costal black dots. Fabr. Found in Germany.

Lyncea. Front and thorax glaucous, with four ocellar dots; wing-cases hyaline, with yellowish margin. Fabr. A native of the East Indies.

Picta. Head and thorax yellowish, with black spots; wing-cases pale; stripe and two dots black. Fabr. Inhabits Germany.

Brunnea. Yellow; thorax grey; wing-cases testaceous, and without spots. Fabr. A native of Germany.

Grisea. Grey, immaculate; wing-cases flat. Fabr. *Cicada plana*, Gmel. Inhabits Italy.

2-Guttata. Pale, golden rufous, with four white dorsal dots. Fabr. Found in Germany.

4-Notata. Greenish; head yellow, with four black dots; wing-cases whitish. Fabr. Inhabits France.

4-Verrucata. Yellow, with four black dots on the head; wing-cases glossy-golden. Fabr. Inhabits Italy.

Fulgida. Yellow; wing-cases golden fuscous. Fabr. Inhabits England.

Diadema. Head yellow, with two abbreviated black bands; wing-cases fuscous hyaline. A native of Germany.

Reticulata. Fuscous-green: wing-cases fuscous, and somewhat reticulated with white. Inhabits South-American islands.

Punctata. Wing-cases yellowish, with fuscous dots. Geoffroy. An European insect.

Rosæ. Yellow; wings white; tip striated with fuscous. Linn. Found on the leaves of the rose.

Maculata. Grey; wing-cases with fuscous dots and tip; wings white, and at the tip fuscous. Fabr. Found on plants in Europe.

2-Pustulata. Yellow; head with two frontal rufous dots; wing-cases testaceous and hyaline. Inhabits Germany.

Aurata. Yellow; wing-cases marked with fulvous, and four black dots, gilt behind. Linn. Inhabits Sweden.

Ulmi. Wings yellowish-green; tips black, and glossed with golden. Linn. Geoffroy. Inhabits Europe.

Triangularis. Testaceous, spotted with yellow; wing-cases at the base whitish. Inhabits Denmark.

Nitidula. Wing-cases pale golden; wing-cases hyaline, with two brown bands. Donov. Brit. Inf. &c. Inhabits Europe.

I

Virescens.

Virescens. Greenifh; wing-cafes whitifh, and immaculate. A native of Germany. Fabr. *Cicada viridans*, Gmel.

Flavescens. Pale yellow, immaculate; wing-cafes and wings white and hyaline. Fabr. Same country as the preceding.

Cuspidata. Grey; head flat, depreffed, and fufcous at the tip. Fabr. A fmall infect, and inhabits England.

Quercus. Yellowifh; wing-cafes fanguineous, with a brown fpot at the tip. Fabr. An European infect found on the oak.

Spinosa. Front retufe, yellow; wing-cafes green, with three whitifh bands; eyes fpinous. Fabr. Suppl. Inhabits the ifle of France.

Orbona. Head and fcutel fulvous, reticulated with black; wing-cafes black, with the tip dufky cinereous. Fabr. Suppl. Inhabits America.

Dænais. Green; wing-cafes hyaline, with the tip black. Fabr. Suppl. Country unknown. Cabinet of Weber.

Graminea. Green; head fomewhat elevated, with a black dot at the tip. Fabr. Suppl. Inhabits Italy.

Cruenta. Above fcarlet, variegated with black. Fabr. Suppl. Inhabits Cayenne.

Festiva. Black; head and thorax with a broad dorfal fnowy ftripe; wing-cafes black, with two fcarlet fpots. Fabr. Suppl. A fmall infect, found in Cayenne.

Parvula. Dufky; wing cafes black; dot in the middle, and tip hyaline. Fabr. Suppl. Found in Cayenne. Cabinet of Richard. A minute fpecies.

* *Cicada*, Panzer.

Genus *Delphex*, Fabr. Suppl.

Crassicornis. Pale; wing-cafes white, varied with teftaceous. A native of Germany.

Clavicornis. Fufcous; wing-cafes hyaline, with a fufcous ftreak behind. Inhabits France.

* *Cicada*, Linn. &c.

Genus *Cercopis*, Fabr.

Gigas. Head and thorax pale, with four ferruginous lines; wing-cafes fufcous, with a band and three dots of white. Fabr. Suppl. One of the largeft infects of the genus *Cercopis*. Defcribed from a fpecimen in the cabinet of M. Dymeril. Found in Cayenne.

Bicolor. Black; wing-cafes teftaceous; future, and daub behind black. Fabr. A native of the Cape. Size of the laft.

Transversa. Head and thorax black, with yellow band; wing-cafes pale and immaculate. Fabr. Suppl. Found on plants in Europe.

Lateralis. Black, with a narrow line, and fpeckling of yellow; margin of the wing-cafes fanguineous. Fabr. Suppl. Inhabits Carolina.

Albipennis. Pale; thorax fufcous; wing-cafes white, with a fpot at the bafe, and an oblique ftreak of fufcous. Fabr. Inhabits France.

Grossa. Wing-cafes fufcous-grey, with a marginal, fulvous, and cinereous fpot. Fabr. Inhabits Africa, and is a large fpecies. *Cicada afra*, Gmel.

Marginata. Black; wing-cafes with a marginal fanguineous ftripe on each fide. Fabr. *Cicada atra*, Gmel. Inhabits America.

Maculata. Thorax black, with a fulvous band; wing-cafes fulvous, fpotted, and tipped with black. Fabr. *Cicada maculofa*, Gmel. An African fpecies.

Coccinea. Red, immaculate; pofterior fhanks fingle toothed. Fabr. Found in the American iflands.

Rubra. Sanguineous; wing cafes with two obfolete fufcous fpots. Fabr. Inhabits Senegal.

Sanguinolenta. Black; wing-cafes with two fpots, and a band of fanguineous red. Linn. Donov. Brit. Inf. Inhabits Europe.

Analis. Black; wing-cafes fanguineous, with a whitifh fpot in the anal angle. Fabr. Inhabits the Cape of Good Hope.

Obscura. Deep black; wing-cafes dufky black. Fabr. A native of Guinea.

Schach. Black; wing-cafes fufcous, with an interrupted fanguineous band. Defcribed from the Hunterian Cabinet. Fabr. An American fpecies.

Cruentata. Rufous; wing-cafes black, with two yellow bands. Fabr. *Cicada rubra*, Linn. Inhabits Surinam.

Versicolor. Black, gloffy; wing-cafes with two white fpots at the bafe, and a fingle rufous one in the middle. Fabr. Inhabits Tranquebar.

Atra. Black, gloffy; wings whitifh. Fabr. Inhabits the fouth of Europe. *Cicada nigra*, Gmel.

Viridis. Green; wing-cafes with an outer hyaline margin. Fabr. A native of American iflands. *Cicada virens* of Gmelin.

Nebulosa. Yellowifh; wing cafes fufcous with an oblique band, nnd two daubs of yellowifh. Fabr. Inhabits the Eaft Indies. *Cicada nebula* of Gmel.

Carnifex. Sanguineous; fpot on the thorax, and two ftripes on the wing-cafes black. Fabr. Inhabits New Holland. Donov. Inf. New Holland.

Varia. Head and thorax greenifh; wing-cafes fufcous with two fpots at the bafe, and ftripe behind yellow. Fabr. Inhabits Cayenne.

4-Fasciata. Yellow, with four fufcous bands. Linn. Inhabits Surinam.

Spumaria. Fufcous; wing-cafes with two whitifh lateral fpots. Linn. Inhabits Europe.

Pellucida. Greyifh, with a hyaline band acrofs the wing-cafes. Donov. Inf. New Holland.

Maura. Black; breaft and abdomen fanguineous. Donov. Inf. New Holland.

Aurata. Cinereous, golden, gloffy, and without fpots. Fabr. Inhabits Cayenne.

Marginella. Black; head, thorax, and wing-cafes margined with white. Fabr. Inhabits Europe.

Leucophthalma. Black; eyes white. Linn. Inhabits the north of Europe.

Leucocephala. Head and thorax at the bafe yellowifh. Linn. Found in Sweden, and other parts of Europe.

Striata. Black, two yellow bands on the head; wing-cafes ftriated with white. Fabr. Found on plants in Germany.

Lineata. Yellowifh; wing-cafes with three black ftreaks. Fabr. Inhabits Germany.

Vittata. Above cinereous, with a black ftripe. Fabr. Inhabits France.

Coleoptrata. Wing-cafes entirely coriaceous, and covering the wings, grey, with a fufcous dot in the middle. Fabr. Inhabits Germany and France.

Angulata. Black; above pale; wing-cafes with a fmall line at the bafe, and two fufcous ftreaks uniting at the exterior margin. Fabr. Inhabits Sweden.

Præusta. Cinereous; fcutel at the bafe black; wing-cafes fufcous at the tip. Fabr. Same country as the preceding.

Immaculata. Dufky, and without fpots; wing-cafes ftriated. Fabr. Inhabits Italy.

Aptera. Fufcous; wing-cafes coriaceous and pellucid; no wings. Fabr. A fmall fpecies found on the coaft of Barbary.

Grylloides. Yellowifh; wing-cafes coriaceous, varied with fufcous; no wings. Fabr. An Italian fpecies.

Pedestris. Wing-cafes coriaceous, abbreviated; tail fetaceous; no wings. Fabr. Inhabits Europe.

Rustica. Grey, immaculate; wings white. Fabr. An European fpecies, found on plants.

Gibba. Black; wing-cafes fpotted with white. Fabr. Inhabits Denmark.

Biguttata. Black, fpotted with yellow; wing-cafes fufcous; marginal fpot white. Fabr. A native of Germany.

Ruficollis. Black; thorax rufous; wing-cafes varied with rufous, and fufcous. Fabr. Inhabits Italy.

Variegata. Head and thorax black, with a yellowifh ftreak; wing-cafes yellow, ftriated with yellow.

Fasciata. Yellowifh; wing-cafes dufky; band and two fpots of white. Fabr. Inhabits Europe.

Unifasciata. Cinereous; wing-cafes with an oblique fufcous band. Fabr. Inhabits Italy.

2-Fasciata. Yellowifh; wing-cafes fufcous, with two whitifh bands. Linn. Found in Sweden.

Capitata. Black; head teftaceous; a black band beneath. Fabr. Inhabits Paris. Bofc.

3-Fasciata. Black; thorax, and two bands on the wing-cafes whitifh. Inhabits Paris.

Striatella. Fufcous; head and thorax with a greenifh band; wing-cafes with many greenifh lines. Fabr. Inhabits Paris.

Histrionica. Black; head and thorax yellow, variegated; wing-cafes ftriated with paler, and a fufcous ftreak behind.

Populi. Clouded; two dots on the crown, and bafe of the abdomen black. Linn. Found on plants in Europe.

Reticulata. Wing-cafes varied with pale, and ferruginous; difk reticulated with black. Fabr. Found on plants in Europe.

CICÆ, in *Ancient Geography*, ifles of the ocean, fituated, according to Pliny, on the weftern coaft of Spain. Ptolemy calls them "Deorum Infulæ." They are the ifles of Bayonne. M. D'Anville marks them in his chart on the coaft of the Callaici, oppofite to a fmall gulf, N.W. of Tyde.

CICATRICULA, in *Natural Hiftory*, a little whitifh fpeck, or veficle, in the coat of the yolk of an egg; wherein the firft changes appear towards the formation of the chick. The *cicatricula* is what is otherwife called the eye of the egg.

CICATRIX, in *Surgery*, is fynonymous with a fcar or feam in the fkin, which remains after the healing of a fore, &c. This word is derived from the Latin *cicatrico*, to heal up, and was formerly fpelt cicatrice, after the French. The older furgeons fancied they had the power of cicatrizing wounds at pleafure, and that certain remedies poffeffed the faculty of producing good cicatrizations; but we have learned to be much more diffident of our abilities in this refpect, on obferving that it is wholly a procefs of nature, and that the furgeon is not able to do any thing towards producing it, although he may eafily prevent the formation of a cicatrix.

It is evident that cicatrices differ in their texture and compofition from true fkin, becaufe they ufually have neither blood-veffels nor nerves; and, in brute-animals, this new-formed fubftance will feparate, fo as to leave holes in the fkin, on its being fubmitted to the operation of tanning. We know of no author who has treated fo amply, and (for the moft part) fatisfactorily on the formation of a cicatrix, as Mr. James Moore, in a differtation printed A.D. 1789, by order of the Lyceum Medicum Londinenfe. He fays, as cavities are filled up in a different manner, during the adhefive and fuppurative inflammations, there is likewife fome diftinction in the formation of cicatrices during thefe different ftates.

When a wound is healed by the adhefive inflammation, the fkin, as well as the parts more deeply feated, throws out the inflammatory exfudation, and the whole is united by this exfudation and extravafated blood.

Upon the furface of the fore a dry cruft is formed; this confifts partly of the extravafated blood, and partly of an exfudation from the wound, which after coagulation hardens by the evaporation of the watery parts. This cruft or fcab adheres to the lips of the wound; if it is removed it gives fome pain; the fore is then obferved moift with a tranfparent fluid, and there generally follows an oozing of blood, fome of the new veffels of the uniting medium being torn. The cruft does not become organized, but remains like dead foreign matter. Immediately under it, and on a level with the cutis, the new fkin forms, and covers the uniting medium. This new fkin is a fine delicate membrane; but it gradually becomes thicker and ftronger. The cruft, at firft, adheres to it fo ftrongly that if it is attempted to be removed the cicatrix will be torn off with it. But when left to itfelf the cruft becomes hard, dry, and fhrivelled; gradually loofens from the cicatrix and then drops off. The fcar now appears red; but foon acquires a brown colour, and at laft changes to nearly the fame appearance as the old fkin, though rather more white and gliftening.

When a wound or fore heals by the fuppurative inflammation, the cicatrix does not begin to form until the granulations have arifen to the furface of the old fkin, or nearly fo.

When the healing is moft favourable, the granulations arife exactly to the level of the fkin; if they fhoot much higher no cicatrix will form, until the exuberancy is removed by an internal procefs, or by the furgeon's art; and if the granulations are much too low, the cicatrix likewife does not form. A mathematical exactnefs, however, is not required; for cicatrization generally takes place when the granulations are nearly of the fame height, although ftill a little higher or lower than the old fkin.

The formation of the cicatrix begins from the edges of the old fkin. The rednefs which exifted during the inflamed ftate abating, the fwelling fubfiding, and the edges of the fore uniting with the rifing granulations. The margin then acquires a bluifh white or pearly colour, which gradually extends itfelf to the centre till the whole fore is covered with new fkin. It fometimes happens in broad fores, that cicatrization takes place, not only from the circumference, but likewife from one or two points in the centre; thefe appear like iflands in the midft of a fea of granulations; they are of the fame colour as the healing margin; and they become larger by extending in every direction. In confequence of cicatrization going on from different central parts, it happens not unfrequently during the progrefs of healing, that one broad fore is divided into two or three fmaller ones; and when this happens the cure muft go on fafter. There is always more or lefs of a cuticular covering upon the cicatrix, which being conftantly constantly moistened by the discharge from the granulations is soft and pulpy, and occasions that whitish colour observable on the edges of healing sores. I have sometimes removed this cuticular substance, and have observed underneath the real new skin, which seems a very fine membrane of a red colour, the granulations shining through it.

When a suppurative sore is nearly healed, if it is not kept moist by some application, a scab is apt to form in the same manner as in those wounds which are healed by the first intention. This crust consists of pus dried by the evaporation of the watery parts; the new skin forms under it, and it soon after falls off.

From the surface of the cicatrix there is no secretion; there are only the perspirable vessels. While it is forming, it is kept moist by the discharge from the uncovered granulations; but when completely formed, the cicatrix is as dry as any other skin.

It appears that the new skin at first cannot form a good cuticle and rete-mucosum, for there is always a succession of scales falling off for some time; at last this ceases, and the new skin is covered with a good cuticle and rete-mucosum, like other parts. The cicatrix changes successively from a reddish colour to a brown; and lastly it becomes whiter, and of a more shining appearance than the original skin. This is a curious circumstance and merits some attention.

The cutis, as every anatomist knows, is not a smooth polished membrane, but is full of eminences, which are named papillæ. These, in some parts of the body, run in waving rows, and form in others irregular lozenges and triangles. The rete-mucosum and cuticle, which lie immediately over the cutis, are marked with furrows analogous to the eminences of the cutis. The cuticle is of a light colour, and semi-transparent. The rete-mucosum is white, yellowish, brown, or black, in men of these various colours. And the cutis is extremely vascular; the blood contained in these vessels shines through, and gives the florid fleshy tint to the body. The colour of the skin, then, depends partly upon the rete-mucosum, and partly upon the blood which circulates in the cutis. In white men the cuticle and rete-mucosum, which cover cicatrices, appear similar to that which covers other parts; but there is a great difference in the quantity of blood which circulates in the old and new skin. For the new is far less vascular than the old; or, at least, the greater number of its vessels are of a much smaller diameter, and admit a lesser quantity of the red globules of the blood. It happens in consequence of this, that cicatrices are of a whiter colour than the original skin. In negroes, the reverse takes place, their scars being generally blacker than other parts, owing to a darker rete-mucosum forming in them upon scars, than upon the old skin.

Besides the difference of colour, a cicatrix has a glossy, shining look, which the skin does not possess: this is owing to the scar being a smooth polished membrane without hair, or any of those papillæ which are upon the cutis; both the papillæ and hair are parts which are formed in the first organization of the body, and are never afterwards produced.

As scars are less vascular than the old skin, it is probable that they have fewer nerves; for blood-vessels and nerves are generally in proportion to each other. But as nerves can hardly ever be traced to the surface of the body, we can only judge of their number there, by the degree of sensibility; and this is considerably weaker in cicatrices than in the old skin. This indeed might naturally be expected, for scars have no papillæ, which are supposed to be the principal seat of the sense of feeling in the skin. It is observed, that scars are generally far less moveable than the original skin; the latter being commonly attached by a loose cellular membrane to the deep seated parts; whereas the scar forms itself immediately upon the granulations, and is so intimately connected, as to make the same substance with them. This is the reason, likewise, that although a scar is, at first, exactly level with the skin, yet after a certain period, it often is very much depressed. For during the healing of a sore, particularly if the discharge is great, the fat and neighbouring flesh are considerably wasted by absorption. But when the whole is healed, the internal parts recover their bulk, and the fat is regenerated. The skin being attached loosely, readily yields and accommodates itself to this increase; whereas the cicatrix adhering closely, and being, as it were, tacked down to the parts upon which it is formed, appears depressed.

It sometimes happens that a cicatrix, instead of being depressed, rather projects above the skin, owing to the exuberancy of the granulations upon which it is formed; and very often the scar has an irregular unseemly appearance, from the granulations rising to unequal heights.

Its appearance is so different from real skin, that although every one agrees that it is not the same, yet there are very different opinions with respect to what it really is.

Some authors assert that it is a distinct membrane; others, that it is only the cellular membrane condensed; or, as one or two French writers have termed it, an exsiccation of the surface of the sore. Mr. Bell of Edinburgh, in his excellent System of Surgery, says, "That a dry pellicle of a scarf-skin forms over wounds."

But it is certain that, upon every cicatrix there is both a cuticle or scarf-skin, and likewise a rete-mucosum, which may be raised by a blister in the living body; or may be removed in a dead body by maceration. After these membranes are taken away, there is discovered underneath a smooth polished surface, which is, properly speaking, the new skin. If it is attempted to dissect this from the deep seated parts, there is found no line of separation, no distinction of parts, but all is uniform. The operator, therefore, if he persists in his attempt, does not know whether to cut to the depth of the fourth, eighth, or tenth of an inch; the substance of the whole, except the smooth external surface, being similar.

It is, therefore, a mere dispute of words to contest whether there is a new membrane or not. If it is said that there is one, it must be allowed to be so intimately attached to the parts upon which it is formed, that no separation can be observed. And if there is said to be no new membrane, it must be granted that the surface of the sore loses its extreme vascularity, the power or disposition of secreting pus, and becomes smooth, polished, and able to form a cuticle and rete-mucosum.

The substance of the new skin is, then, exactly (or, in many respects) of the same nature with the new flesh upon which it forms; and although it has by no means the same elasticity as the old skin, yet it is nearly as strong and able to resist mechanical violence. It is, therefore, a good substitute for the other.

The difference in its appearance from the original skin is at first striking; this dissimilarity gradually lessens with time, but never vanishes entirely. For as the scar cannot acquire the papillæ, or the same degree of vascularity with the cutis, it continues distinguishable during life; as is proved by the wound of even the finest lancet in bleeding.

But in superficial cuts, in those small abscesses called pimples, and other slight ulcerations, and in the mild species of the small-pox, where the surface of the cutis only is affected, and where it is not pierced through, no lasting scar is left Because in these cases an entire portion of new skin is not required,

quired, as fome of the old remains, from which the roots of the papillæ and hair fhooting up, the temporary fcar difappears and the part regains its former appearance. But when the puftules of the fmall-pox, or other ulcerations, corrode fo deep as to deftroy the cutis or papillæ, the cicatrix or fcar never difappears; as is often cruelly exemplified in the bad fpecies of fmall-pox. The puftules fometimes heal with a depreffion or pit, as it is called; and fometimes where no pit is left, but all is level, a gliftening white mark remains for ever. For papillæ once deftroyed never again fpring up; for which reafon the cicatrix never acquires an equal degree of vafcularity with the original fkin.

Some ingenious remarks occur likewife on the fubject "*Of Skinning*," in Mr. John Hunter's book upon inflammation and wounds, chap. viii.

CICATRIZE, to heal with new fkin. See CICATRIX.

CICCA, in *Botany*, Linn. Mant. I. p. 17. Schreb. 1417. Juff. 385. Mart. Clafs and order, *monœcia tetrandria*. Nat. ord. *Euphorbiæ*, Juff. Gen. ch. Male. *Cal.* Perianth four-leaved; leaves roundifh, concave. *Cor.* none. *Stam.* four, briftle-fhaped; anthers fomewhat globular, the length of the calyx. Female. *Cal.* and *Cor.* as in the male. *Pift.* Germ roundifh; ftigmas four, two-parted, awl-fhaped, the length of the germ; ftigmas acute, permanent. *Peric.* Berry four-celled. *Seeds* folitary.

Eff. Ch. Calyx compofed of four roundifh leaves. Pericarp a four-celled berry. Nearly allied to Phyllanthus, but differs in the number of parts, and having a berry for the fruit.

Sp. 1. C. *difticha*, Linn. Mart. 124. Mart. Lam. Encyc. Illuft. Pl. 757. fig. 6. "Male and female flowers in feparate racemes on the naked part of the branches." A tree with long fimple branches. *Leaves* in two alternate rows on fhort petioles; the lower ones rounded, egg-fhaped, fmaller; upper ones ovate-lanceolate, acuminate; entire, very fmooth. *Flowers* proceeding from the lower part of the branches, after the falling of the leaves, and occupying their places. A native of the Eaft Indies. The younger Linnæus has fuppofed this plant to be the averrhoa acida of his father; but whatever it may be, it certainly is not an averrhoa. See AVERRHOA. 2. C. *nodiflora*, Lam. Encyc. Illuft. Pl. 757. fig. 2. "Flowers aggregate, axillary." A fhrub. *Leaves* on fhort petioles, egg-fhaped, acute, fmooth, entire, fometimes almoft round, with a fmall point at their fummit. *Flowers* extremely fmall. *Fruit* a globular berry; with four fmall, permanent, expanding ftyles. A native of the ifland of Java.

Loureiro has a fpecies which he calls C. racemofa, the terme of Gærtner, who has preferved its Japanefe name. He defcribes it as a middle-fized tree, with afcending branches. Leaves egg-fhaped, fomewhat acuminate; quite entire, fmooth, alternate, petioled, in two rows. *Flowers* in compound, fhort, nearly terminal racemes; males and females on different branches. He afferts, that what Linnæus calls the calyx is properly a bell-fhaped, four-cleft corolla; the fegments egg-fhaped, fpreading, red, dotted with white; filaments fhorter than the corolla; anthers two-celled. *Fruit* a roundifh berry, half an inch in diameter, pale, fmooth, acid, eatable. *Seeds* four, egg-fhaped. A native of Champava. Cultivated, but rarely, in the capital of Cochinchina. See TERME.

Profeffor Martyn has given averrhoa acida of Linnæus, as a fynonym to C. racemofa of Loureiro, but he afterwards doubts their identity.

CICCIONE, ANDREA, in *Biography*, a Neapolitan fculptor and architect of great eminence of the 14th and 15th centuries; he was the difciple of Mafuccio the fecond. Amongft his beft works in architecture, are the famous monaftery and church of Monte Oliveto, and the beautiful palace erected for Bartolommeo du Capua, prince della Riccia, at St. Biagio de Librari; and the third cloifter, of the Ionic order, at S. Severino. His greateft work of fculpture is the monument, erected, in the church of St. Giovanni, by order of Giovanna, then queen of Naples, to the memory of her brother the young king Ladiflaus, who died 1414. It is all of white marble; four figures, reprefenting Temperance, Fortitude, Prudence, and Magnanimity, are introduced in place of pilafters to fupport the fabric; over thefe, under a great arch, are feated two figures reprefenting Ladiflaus and his fifter; on the top of the arch is a fepulchral urn, ornamented with baffo relievos, upon which lies the refemblance of the dead king, difcovered to the fight by two angels who draw afide a curtain; above this the monument rifes in a pyramidical form, completed with a cornice, where the figure of Ladiflaus is once more reprefented, with a martial deportment, feated on horfeback, in complete armour. Ciccione died, much regretted, at a very advanced age in the year 1455. Domenici, Vita del Pitt. Scul. & Arch.

CICELY, in *Botany*. See SCANDIX *odorata*.

CICER, Linn. gen. 875. Schreb. 1189. Juff. 361. Vent. 3. 420. Gært. 872. Clafs and order, *diadelphia decandria*. Nat. ord. *Papilionaceæ*, Linn. *Leguminofæ*.

Gen. Ch. *Cal.* one-leaved, five-cleft, as long as the corolla; the four upper fegments incumbent on the ftandard; the fifth fmaller, placed under the keel. *Cor.* papilionaceous; ftandard roundifh, larger than the other petals; wings approaching each other rather obtufe; keel fhorter than the wings. *Stam.* filaments ten, diadelphous, afcending; anthers fimple. *Pift.* germ fuperior, egg-fhaped; ftyle afcending; ftigma obtufe. *Peric.* legume rhomboidal, turgid, inflated. *Seeds* two or more, almoft globular, with a fmall point at their bafe.

Eff. Ch. Calyx five-cleft, the length of the corolla; four upper fegments incumbent on the banner. Legume rhomboid, turgid.

Sp. 1. C. *arietinum*, Linn. Sp. Pl. Willd. 1358. Mart. Lam. Illuft. pl. 632. Gært. tab. 151. (C. fativum, Bauh. Pin. Tourn. cl. 10. gen. 2. Ciche. Lam. Encyc.) Common cich or ciches. "Leaves unequally pinnated; leaflets ferrated; legumes two-feeded." Lam. *Root* annual. *Stem* from a foot to eighteen inches high, erect, leafy, branched, fpreading, angular. *Leaves* compofed of about eight pairs of leaflets with an odd one, egg-fhaped, finely ferrated, hairy. *Flowers* fmall, purple or white; peduncles axillary, folitary, one-flowered, bent, furnifhed with a fhort thread near the angle. *Seeds* one or two, fometimes nearly globular, with a fhort beak at the navels, fometimes angular, with a fancied refemblance to a ram's head, whence the trivial name. A native of the fouth of Europe, where it is cultivated like other pulfe for agricultural purpofes. It is cut feveral times in the fpring, and given green to fheep and lambs, to whom it is efteemed peculiarly nourifhing. It is alfo faid to increafe the milk of cows, who eat it with avidity. Its feeds are eaten in its native climate, both raw and boiled, but do not always agree with delicate ftomachs, efpecially when cultivated in a colder climate. They are fometimes ufed as a fubftitute for coffee, when roafted to blacknefs, pulverized and boiled in water. In warm and dry weather there is fecreted from the tips of the hairs of the leaves, a tranfparent acid liquor which corrodes the fhoes and ftockings of thofe who walk over the fields where it is fown, and which, according to Deyeux (Journ. de Phyf. Flor. An. 6.) is a pure oxalic acid. 2. C. *nummularifolium*,

rifolium, Lam. Encyc. (Elatines folio ſubrotundo; folliculis hirſutis turgidis, Pluk. Amalth. tab. 389. fig. 5.) "Leaves ſimple, inverſely egg-ſhaped, quite entire, hairy; legumes generally more than two-ſeeded." Lam. *Stems* ſlender, about a foot and half long, hairy, branched, leafy. *Leaves* alternate, ſomewhat egg-ſhaped, or roundiſh, entire, hairy. *Flowers* two or three, reſembling thoſe of the preceding ſpecies, but rather ſmaller; peduncles lateral, axillary, hairy. *Legumes* ſomewhat egg-ſhaped, inflated. *Seeds* ſomewhat heart-ſhaped. A native of the Eaſt Indies; communicated to La Marck by Sonnerat. La Marck pronounces it to be perfectly diſtinct from glycine monophylla of Linnæus, and aſſerts that, notwithſtanding its difference in habit, its fructification is properly that of cicer; but Juſſieu doubts whether it ought not rather to be referred to crotalaria.

CICERO, Marcus Tullius, *in Biography*, was born on the third of January, in the year of Rome, 647, about 107 years before Chriſt. His birth, if Plutarch is to be believed, was attended with prodigies, foretelling the future eminence of his character. But theſe are to be aſcribed to the credulity or invention of a writer, who wiſhes to excite curioſity by the appearance of what is marvellous. The name Marcus, which he derived from his father and grandfather, was properly perſonal, equivalent to that of baptiſm with us, and impoſed with ceremonies analogous to the chriſtian on the ninth day, called the luſtrical or day of purification. Tullius was his family name, which in the old Latin, as apparently derived from the oriental term דלל *dalal*, ſignified a *flowing ſtream*, ſuggeſted, it is probable, from their ſituation at the confluence of two rivers. As Tullius, the family name, was ſuggeſted by the ſituation of the farm; ſo Cicero, the ſirname, was borrowed from the *vetches*, which were chiefly raiſed and cultivated in it. Agriculture was regarded by the Romans as the moſt liberal employment; and thoſe families, who reſided on their farms in the country, as the moſt honourable. Pliny in his Nat. Hiſt. 18. 3. 1, aſſures us, that all thoſe names which diſtinguiſhed any ſpecies of grain, ſuch as the Fabii, Lentuli, &c. were acquired by the reputation of being the beſt cultivators of that ſpecies. The grain *cicer*, which gave our author the appellation of *Cicero*, was held in all ages of the republic in great eſteem by the Roman populace, as it conſtituted a principal article of thoſe bounties beſtowed upon them by the rich, and was ſold every where in the ſtreets, and prepared for immediate uſe by being ready parched or boiled.

Moſt great men owe much of their early improvement, and conſequently of their future celebrity, to maternal education. But to this general fact Cicero appears an exception, unleſs we ſuppoſe him to have been no leſs deſtitute of filial gratitude than he was of affection. Of his mother, whoſe name was Helvia, a name noticed in hiſtory, and found on old inſcriptions among the honourable families of Rome, no mention is made in any part of his writings; though the little incident of domeſtic management, recorded by his brother Quintus, ſhews that ſhe was equally entitled to the attachment of her children and the imitation of her neighbours. But the indifference or averſion, which induced our author to omit the tribute of veneration due to the memory of his mother, betrays itſelf in the very unpardonable levity with which, in a letter to Atticus, he notices the death of his father.

His paternal family, though not ennobled by any of the great offices of the republic, was yet ancient and honourable, of the firſt diſtinction in that part of Italy in which it reſided, and of equeſtrian rank from its firſt admiſſion to the freedom of Rome. And though he could not with truth boaſt of the ſplendour of his anceſtors, he ſpeaks of them, when occaſion required, with great complacency and frankneſs, as having lived content with their paternal fortunes, and the private honours of their own city, without the ambition of appearing on the public ſtage of Rome. It is for this reaſon that we find him ſo often called a new man; not that his family was new or ignoble, but becauſe he was the firſt of it who ever ſought and obtained the public magiſtracies of the ſtate.

The place of his birth was Arpinum, a city anciently of the Samnites, now part of the kingdom of Naples; which upon its ſubmiſſion to Rome acquired the freedom of the city and was inſerted into the Cornelian tribe. It had the honour alſo of producing the great Caius Marius, which induced Pompey to ſay on a public occaſion, that Rome was indebted to this corporation for two citizens, who had each in his turn preſerved it from ruin. It may juſtly, therefore, claim a place in the memory of poſterity for giving life to ſuch worthies, who exemplified the character which Pliny gives of true glory, "by doing what deſerved to be written, and writing what deſerved to be read," and thus making the world the happier and the better for their having lived in it. The family ſeat was about three miles from the town of Arpinum, in a ſituation extremely pleaſant and well adapted to the nature of the climate. It was ſurrounded with groves and ſhady walks leading from the houſe to a river called Fibrenus, which was divided into two equal ſtreams by a little iſland covered with trees, and a portico contrived both for ſtudy and exerciſe, whither Cicero was uſed to retire when he had any work upon his hands. The clearneſs and rapidity of the ſtream murmuring through a rocky channel, the ſhade and verdure of its banks, planted with poplars, the remarkable coldneſs of the water, and, above all, its falling by a caſcade into the noble river Liris, a little below the iſland, give us the idea of a moſt beautiful ſcene. The houſe, as Cicero deſcribes it, was but ſmall and humble in his grandfather's time, according to the ancient frugality, like the Sabine farm of old Curius, till his father beautified and enlarged it into a handſome and ſpacious habitation. But there cannot be a better proof of the delightfulneſs of the place than that it is now poſſeſſed by a convent of monks, and called the villa of St. Dominic. Strange revolutions, adds Dr. Middleton, to ſee Cicero's portico converted to monkiſh cloiſters! the ſeat of the moſt refined reaſon, wit, and learning, to a nurſery of ſuperſtition, bigotry, and enthuſiaſm. What a pleaſure muſt it give theſe Dominican inquiſitors to trample on the ruins of a man, whoſe writings, by ſpreading the light of reaſon and liberty through the world, have been one great inſtrument to obſtruct their unwearied pains to enſlave it!

The firſt care of his father Marcus, whoſe wiſdom and learning recommended him to the principal magiſtrates of the republic, was to give his ſon the beſt education which Rome could afford, in hopes to excite in him the ambition of aſpiring to the higheſt offices of the ſtate. Accordingly he was brought up under the direction of L. Craſſus, a man of the firſt dignity as well as the firſt eloquence in Rome. The Romans were careful and exact in the education of their children; their attention to it began from the time of their birth, when they committed them to the care of ſome reputable matron, whoſe buſineſs it was to form their firſt habits of acting and ſpeaking, to watch their growing paſſions, and direct them to their proper objects, to ſuperintend their ſports, and to prevent any thing indecent or improper from entering into them, that the mind, preſerved in its native innocence, might be at liberty to purſue whatever was laudable, and apply its whole ſtrength to that profeſſion in which it deſired to excel. This formed a part of that domeſtic diſcipline in which our author was trained, and of which he often ſpeaks. But as ſoon as he was capable of a more liberal inſtruction, his father brought him to Rome and placed him in a public ſchool under an eminent Greek maſter, as the moſt eligible method of educating one who was deſigned to appear on the public ſtage, and who, as Quintilian obſerves, "ought to be ſo bred as not to fear the ſight of men, ſince that can never be learned in ſolitude which is to be produced before crowds." Here he gave the firſt ſpecimens of thoſe ſhining abilities, which rendered him afterwards ſo illuſtrious; and his ſchool-fellows carried home ſuch ſtories of his extraordinary talents, that their parents were often induced to viſit the ſchool, for the ſake of ſeeing a youth endowed with ſuch ſurpriſing faculties.

Encouraged by the promiſing genius of his ſon, the father ſpared no expence in improving it by the help of the ableſt maſters. Among the inſtructors of his youth, was the poet Archias, who, with a high reputation for learning and taſte, opened a ſchool in the family of Lucullus, when Cicero was only five years old. Notwithſtanding this early age, he applied himſelf under this maſter to poetry, and made ſuch a proficiency in it, that, while he was ſtill a boy, he compoſed and publiſhed a poem, called "Glaucus Pontius," which, though now loſt, was extant in the days of Plutarch. Having finiſhed his youthful ſtudies, he laid aſide the habit of the boy for that of the man, and aſſumed what was called the *manly gown*, or the robe of the citizen. This ſeaſon, which was about the 17th year in the ancient republic, though probably ſomewhat earlier in the caſe of Cicero, was a period of great joy to the young men; who, by this change, paſſed into a ſtate of greater liberty and enlargement from the reſtraint of their tutors, and aſſumed the dignity and independence of manhood.

Cicero being then introduced into the Forum, a place calculated to call forth all the enthuſiaſm of his talents, as there the popular aſſemblies were convened, the magiſtrates harangued from the roſtra, and judicial proceedings were uſually tranſacted, was placed under the auſpices of Q. M. Scævola, the augur, and at the ſame time the principal lawyer and ſtateſman of that age, all whoſe remarkable ſayings and leſſons of wiſdom he carefully treaſured up in his memory. After his death, he applied to Scævola, the high prieſt, a perſon of the ſame family, and of equal probity and ſkill in the law, though not a lawyer by profeſſion. Under theſe maſters he acquired a complete knowledge of the Roman laws, a qualification uſeful and ornamental in all countries, but in Rome of ſuch conſequence, that one of the common exerciſes, allotted to boys in ſchool, was to learn by heart the laws of the twelve tables, as they did their poets and claſſic authors. Before he was yet called to the bar, he had ſtudied this ſubject even in its moſt intricate and complex branches with ſuch accuracy and comprehenſion, as to be able to ſuſtain a diſpute on any queſtion with the moſt diſtinguiſhed profeſſors of that age; and once, in pleading with his friend Sulpicius, he declared, by way of raillery, what he was probably able to make good in fact, that, if he provoked him, he would, in the courſe of three days, profeſs himſelf a lawyer.

The profeſſion of the law, next to that of arms and eloquence, was a ſure recommendation to the honours of the republic, and for that reaſon was preſerved, as it were, hereditary in ſome of the nobleſt families of Rome, who, by giving their advice gratis to all that wanted it, attained the favour of their fellow-citizens, and acquired great authority in all the affairs of ſtate. But Cicero's ambition aſpired to much higher attainments. Aiming at being an univerſal patron, not only of the fortunes, but of the lives and liberties of his countrymen, he wiſhed to become an accompliſhed orator, or pleader of cauſes, whoſe profeſſion, as deſcribed by himſelf, was to ſpeak aptly, elegantly, and copiouſly on every ſubject which could be offered to him, and whoſe art, therefore, included all other arts of the liberal kind, and could not be acquired to any perfection without a competent knowledge of whatever was great and laudable in the univerſe. This was his own idea of the character he had undertaken, and his ambition was to illuſtrate the juſtice of his deſcription by his own attainments and eloquence. For this purpoſe, while he ſtudied the law under the Scævolas, he uniformly attended the pleadings at the bar and the public ſpeeches of the magiſtrates, and at the ſame time ſpent a portion of every day in reading and writing at home. It was his conſtant practice to take notes and make comments on what he read, and he was fond, when very young, of an exerciſe, recommended by ſome of the great orators before him, of treaſuring in his memory the ſubſtance of what he read in verſe or proſe, and then expreſſing the ſame ſentiments in different, but the moſt elegant, words that occurred to him. But finding that the moſt eligible terms were already employed, and becoming by a growing confidence in himſelf leſs diſpoſed to tread in the footſteps of others, he laid aſide this practice, and tranſlated into Latin the ſelect ſpeeches of the beſt Greek orators, a method which gave him the command of the moſt elegant words in his own language, and at the ſame time furniſhed him with an opportunity of enriching it with new terms, formed in imitation of the Greek. Nor did he yet neglect his poetical ſtudies; for Aratus "On the Phenomena of the Heavens," he tranſlated into Latin verſe, fragments of which are ſtill extant, and alſo compoſed an heroic poem in honour of his countryman C. Marius, of which, unfortunately, only a ſmall ſpecimen is preſerved, deſcribing a memorable omen given to Marius from the oak of Arpinum, which, from the ſpirit and elegance of the deſcription, renders it probable, that his poetical genius, if cultivated with the ſame diligence, would ſcarcely have been inferior to his eloquence. He moreover publiſhed another poem called "Limon," of which the ſubject was uncertain, but which, if we may conjecture from the title, was a collection of various flowery pieces. While he was employed in theſe juvenile exerciſes, for the improvement of his ſtyle and invention, he applied himſelf with no leſs induſtry to the ſtudy of philoſophy. Among his firſt maſters was Phædrus, the Epicurean, of whom he was then very fond, and for whom he always retained a particular eſ-

teem,

teem, on account of his learning, humanity, and politeneſs; though a more enlarged experience and more critical judgment of things, led him ſoon after wholly to abandon, and ſtrenuouſly to oppoſe the principles of that ſect.

When the tranquillity of Rome was diſturbed by what writers call the *Italic* or *Marſic* war, begun by a confederacy of the principal cities of Italy, to ſupport their demand of the freedom of Rome; Cicero firſt directed his attention to the art of war, in the diſcipline of which all young men of diſtinction were trained, as neceſſary in an empire raiſed and ſupported by the force of arms. In this war he followed the camp of Sylla, who, deſirous to ſignalize his military talents, and to eclipſe the fame of his rival, Marius, as the ſureſt way of obtaining the conſulſhip to which he was aſpiring, gained many conſiderable victories. The example of this general inſpired our author with the love of glory; and he was no leſs diligent in the army than he was in the Forum, to obſerve every thing that paſſed; and he always contrived to be near the perſon of the chief commander, that no action of moment might eſcape his notice. During the enſuing diſſenſions between Marius and Sylla, in which the greateſt cruelties were perpetrated by both parties, Cicero appears to have taken no active part, but to have reſumed the ſtudy and practice of eloquence: and being now about the age of twenty-one, compoſed thoſe rhetorical treatiſes, which, though unworthy of his maturer judgment, are ſtill preſerved, and are generally conſidered as the ſame with thoſe on the ſubject of invention. At this time he commenced the ſtudy of philoſophy under Philo, a diſtinguiſhed diſciple of the Academic ſchool, who, together with many of the principal Athenians, fled to Rome to eſcape the fury of Mithridates, now maſter of Greece. While he was cultivating the academic philoſophy under the direction of this celebrated profeſſor, he received from Diodotus, the Stoic, lectures in logic, which Zeno uſed to call "a cloſe and contracted eloquence," and eloquence, "an enlarged and dilated logic," comparing the one to the fiſt or the hand doubled; the other to the palm opened. Yet with all his attention to logic and philoſophy, he never ſuffered a day to paſs without ſome exerciſe in oratory, in which he was aſſiſted by the ſkill and direction of Molo, the Rhodian, who, about this time, had eſtabliſhed at Rome a ſchool of rhetoric, and was one of the principal orators, as well as the moſt celebrated teacher of eloquence, in that age. Under his auſpices, with the advantages of talents and induſtry peculiar to himſelf, he hoped ſoon to rival the fame of Hortenſius, who then made the chief figure at the bar, and whoſe praiſes fired him with ſuch ambition of acquiring the ſame glory, that he allowed himſelf ſcarcely any reſt from his ſtudies either day or night. His principal exerciſe in this department was that of declaiming, which he generally performed with his fellow diſciples M. Piſo and Q. Pompeius, two young noblemen, with whom, though a little older than himſelf, he had contracted an intimate friendſhip. With theſe he declaimed occaſionally in Latin, but more frequently in Greek, becauſe the ſuperior copiouſneſs of this language furniſhed a greater variety of elegant expreſſions, and an opportunity of introducing them into his own tongue; and becauſe the Greek maſters, who were far the beſt, could not correct and improve them, unleſs they declaimed in that language.

Thus did he paſs through all that courſe of diſcipline, which he lays down as neceſſary to form the complete orator; a character to which, according to his own deſcription, none ſhould pretend, without being previouſly acquainted with every thing in art and nature; whoſe profeſſion it is to ſpeak upon every ſubject that can be propoſed to him, and whoſe eloquence, without the knowledge of what he ſpeaks, would be but the unmeaning prattle of children. Having learnt the rudiments of grammar and languages from the beſt teachers, gone through the ſtudies of polite letters under the moſt diſtinguiſhed poet, inſtructed in philoſophy by the principal profeſſors of each ſect, acquired a perfect knowledge of the law from the greateſt lawyers, as well as the greateſt ſtateſmen of Rome; having received lectures on oratory from the moſt eloquent maſters of Greece, continually compoſed at home, and declaimed in the Forum under their direction; having, finally, attained all the graces of polite converſation by continued intercourſe with ladies, as well as men of refinement and literature, eſpecially with the daughter of Lælius, and Mucia, wife of the great orator Craſſus, who excelled all others of their ſex, in the delicate uſe of the Latin tongue; with all theſe accompliſhments, he offered himſelf to the bar about the age of twenty-ſix. This was the age in which Demoſthenes began to diſtinguiſh himſelf at Athens. The firſt ſpecimen, which he gave the public of his eloquence, as ſome have ſaid, was in defence of S. Roſcius, who was acquitted to the great honour of his patron. His courage and addreſs in the conduct of the defence being applauded by the whole city, he was from this time conſidered as an advocate of the firſt claſs, and equal to the moſt arduous cauſes. As by this defence he acquired great reputation in his youth, ſo he reflects upon it with pleaſure in his old age, and recommends it to his ſon as the ſureſt way to true glory and authority in his country, to defend the innocent in diſtreſs, eſpecially when they happen to be oppreſſed by the power of the great: "as I have done," ſays he, "in other cauſes, but particularly in that againſt Sylla himſelf in the height of his power." A noble leſſon to all young advocates to apply their talents to the protection of innocence and injured virtue, and to make juſtice, not profit, the rule and end of their labours!

At the age of eight and twenty years, he left the forum, and went to Greece and Aſia, the faſhionable tour of thoſe who travelled for curioſity or improvement. His firſt viſit was to Athens, the chief ſeat of arts and ſciences. Here, under Antiochus, the principal philoſopher of the old academy, he renewed thoſe ſtudies, to which, as he aſſerts, he had been devoted from his earlieſt years, and formed with T. Pomponius, who, from his predilection for Athens and his reſidence there, was called *Atticus*, that memorable friendſhip, which ſubſiſted between them through life, and has been tranſmitted to poſterity as the faireſt model of conſtancy, diſintereſtedneſs and affection. From Athens he paſſed to Aſia, and wherever he went, he collected about him the principal orators of the country, who accompanied him the reſt of his voyage, and with whom he diſputed in every place where he made any ſtay. The chief of his aſſociates was Menippus of Stratonica, the moſt eloquent of all the Aſiatics; alſo Dionyſius of Magneſia, Æſchylus of Cnidos, and Xenocles of Adramyttus, the firſt rhetoricians in all Aſia. "Not content with theſe (adds he) I went to Rhodes; and applied myſelf again to Molo, whom I had heard before at Rome, who was an experienced pleader and a fine writer, and particularly expert in obſerving the faults of his ſcholars, as well as in his method of teaching and improving them. His greateſt trouble with me was to reſtrain the exuberance of a juvenile imagination, always ready to overflow its banks, within its proper channel." At Rhodes he devoted part of his time to the ſtudy of philoſophy, under Poſidonius, the ſtoic, whom he often mentions with reſpect, not only "as his maſter, but his friend."

Having finiſhed the circuit of his travels, he returned to Italy after an abſence of two years, extremely improved, and changed, as it were, into a new man; the vehemence of his voice and action was moderated, the redundancy of his ſtyle and fancy corrected, his lungs ſtrengthened, and his whole conſtitution confirmed. From this voyage, indeed, he muſt have received the greateſt benefits. His education had qualified him for deriving all the advantages from whatever he could ſee or hear in a tour the moſt delightful which the ancient world could furniſh. By his previous knowledge of the laws of Rome, he was able to compare them with thoſe of other cities, and to bring back with him whatever he found uſeful either to his country or to himſelf. He was entertained, wherever he came, in the houſes of the great and of thoſe who were diſtinguiſhed by their knowledge and eloquence, as well as by their birth and fortune, men honoured in their reſpective communities, as the principal patriots, orators, and philoſophers of the age. Theſe, that he might not loſe the opportunity, even on the road, of profiting by their advice and experience, he made the conſtant companions of his travels. No wonder, then, that from ſuch a voyage he ſhould derive every accompliſhment which could improve or adorn a man of ſenſe.

Soon after his return, while Cotta and Hortenſius, his rivals in eloquence and honour, ſtood candidates, the former for the conſulſhip, the latter for the ædileſhip, Cicero claimed the quæſtorſhip; and had the ſatisfaction before all his competitors of being choſen by the unanimous ſuffrage of the tribes, in the thirty-firſt year of his age, and the very firſt in which he was eligible by law. The quæſtors were treaſurers of the republic, and their office formed the firſt ſtep in the aſcent of public honours, and after its expiration opened an immediate door to the ſenate, and an actual admiſſion into it during life. Choſen annually by the people, the quæſtors formed the regular and ordinary ſupply of the vacancies of the ſenate, by which excellent inſtitution, the road to the higheſt offices in the ſtate was laid open to the virtue and induſtry of every private citizen, and the dignity of this ſovereign council maintained by a ſucceſſion of members, whoſe diſtinguiſhed merit had firſt recommended them to the notice and favour of their country.

The provinces of the quæſtors being diſtributed to them by lot, the iſland of Sicily fell to the ſhare of Cicero. This, from the quantity of corn annually raiſed and exported, was called the granary of the republic, and the quæſtor's chief employment in it was to ſupply proviſion for the uſe of the city. The ſcarcity peculiar to this year at Rome made the people clamorous, and gave the tribunes an opportunity of inflaming them the more eaſily, by aſcribing it to the loſs of the tribunitian power, and to their being by that means left a prey to the oppreſſions of the great. To appeaſe the public mind, it was neceſſary, therefore, to export from the iſland large and ſpeedy ſupplies, by which it was likely to be drained, ſo that Cicero had the difficult taſk of furniſhing what was ſufficient for the city, without, at the ſame time, being oppreſſive to the poor natives; yet he managed the matter with ſo much addreſs, that he made very great exportations without any burden upon the province, ſhewing great courteſy to the dealers, juſtice to the merchants, generoſity to the inhabitants, humanity to the allies, and, in ſhort, doing all good offices to every body, by which he gained the love and admiration of the Sicilians, who decreed greater honours to him at his departure, than they ever had before done to any of their chief governors. In the hours of leiſure from his provincial affairs, he employed himſelf very diligently, as he uſed to do at Rome, in his rhetorical ſtudies, agreeably to the rules which he conſtantly inculcates, never to let one day paſs without ſome exerciſe of that kind; ſo that on his return from Sicily, his oratorical talents, according to his own judgment, were in their full maturity and perfection. Before he left Sicily, he made the tour of the iſland, to ſee every thing in it that was curious, and eſpecially the city of Syracuſe, which had always made the principal figure in its hiſtory. Here his firſt object was to diſcover the tomb of Archimedes, of which the inhabitants were ignorant; but knowing it to be engraved with a cylinder, as an emblem of his mathematical genius, and remembering the words inſcribed upon the grave, he diſcovered in a ſpot over-grown with briars, a ſmall column, whoſe head juſt appeared above the brambles, marked with the memorable inſcription; and he left the place with ſaying, that one of the nobleſt cities of Greece, and once likewiſe the moſt learned, had known nothing of the monument of its moſt deſerving and ingenious citizen, if it had not been diſcovered to them by a native of Arpinum. At the expiration of his year, he took leave of the Sicilians by a kind and affectionate ſpeech, aſſuring them of his protection in all their affairs at Rome; in which he was as good as his word, and continued ever after their conſtant patron to the great benefit and advantage of the province. He came away well pleaſed with his own adminiſtration, and flattering himſelf that the public were celebrating his praiſes. But no ſooner had he landed at Puteoli, than awaking from his dream of imaginary applauſe, he found the majority of the people equally ignorant of the quæſtor and his province. The diſcovery mortified his ambition, or rather taught him to apply it with more ſucceſs; for, according to his own account, it made him reflect "that the people of Rome had dull ears, but quick eyes, and that, therefore, it was his wiſdom to keep himſelf always in their ſight, and to make them ſolicitous, not ſo much to hear, as to ſee him; ſo that from this moment he reſolved to continue on the forum, and perpetually to live in the view of the city, without permitting either his porter or his ſleep to debar any man's acceſs to him."

He was now in his 37th year, the proper age for being choſen ædile, which was the firſt public office properly called a magiſtracy; the quæſtorſhip being only a place of truſt without any juriſdiction in the city. Theſe ædiles, as well as all the interior officers, were elected by the people voting in their tribes, a mode of election free and popular, in which he was declared ædile, as he had been before inveſted with the quæſtorſhip, by the unanimous ſuffrage of the tribes, in preference to all his competitors. After his election, but before his entrance on that office, he undertook the famed proſecution of C. Verres, the late prætor of Sicily, charged with many flagrant acts of injuſtice, rapine, and cruelty, during his tyrannical government of that iſland. Verres, guilty and corrupt as he had been in the adminiſtration of his province, was ſupported by the moſt powerful families of Rome, and defended by Hortenſius, who was the reigning orator at the bar, and uſually ſtiled the king of the forum; yet the difficulty of the cauſe, inſtead of diſcouraging, ſerved only to animate him the more, by the greater glory of the victory. The reſult was, that Verres was condemned, and the reputation of Cicero both for abilities and integrity greatly increaſed, as of one whom neither money could bribe, nor power terrify, from proſecuting a public oppreſſor; and the Sicilians ever after retained the higheſt ſenſe of his ſervices, and on all occaſions teſtified the utmoſt zeal for his perſon and intereſt.

After this impeachment, Cicero entered on his ædileſhip, of the duties of which he gives us in one of his ſpeeches an account, and which, however important they might be deemed by him, muſt appear contemptible to a modern reader; "I am now choſen ædile," ſays he, "and am ſenſible of what is committed to me by the Roman people. I am to exhibit with the greateſt ſolemnity the moſt ſacred ſports to Ceres, Liber, and Libera; I am to appeaſe and conciliate the mother Flora to the people and city of Rome, by the celebration of the public games; and to furniſh out thoſe thofe ancient fhows, the firft which were called Roman, with all poffible dignity and religion, in honour of Jupiter, Juno, and Minerva." Of thefe games the people were paffionately fond; and as their gratification in this refpect was the fureft road to popularity, many perfons of wealth, when in office, were ruined by thefe diverfions. Cicero, in the execution of this undertaking, avoided the extravagancies into which other magiftrates had plunged, adopting the middle courfe, "fo as neither to hurt his character by a fordid illiberality, nor his fortune by a vain and oftentatious magnificence; fince the one, by making a man odious, deprived him of the power of doing good, the other, by making him neceffitous, puts him under the temptation of doing ill."

After the ufual interval of two years from the time of his being chofen ædile, he ftood candidate for the prætorfhip, the office of which was to prefide and judge in all caufes, efpecially of a public and criminal nature; and it fell to Cicero's lot to fit upon actions of extortion and rapine, brought againft governors of provinces; in which, as he tells us himfelf, he had acted as an accufer, fat as a judge, and prefided as a prætor. In this office he acquired great reputation for integrity, by condemning L. Macer, a perfon of prætorian dignity, and great eloquence, who would have made an eminent figure at the bar, if his abilities had not been fullied by the infamy of a vicious life. Though fully employed in public affairs as prætor, he found time ftill to act as an advocate, as well as a judge, and not only to hear caufes in his own tribunal, but to plead them alfo at the tribunals of the other prætors; and what furnifhes the moft remarkable proof of his induftry is, that, during his prætorfhip, though he was in the conftant habit of exercifing his eloquence, yet he frequented the fchool of the celebrated rhetorician Gnipho, with the defign, if not to learn fomething new, at leaft to prevent any ill habit from infenfibly growing upon him, by exercifing himfelf under the obfervation of fo judicious a mafter. At the expiration of his prætorfhip, he declined to accept any foreign province, the ufual reward of that magiftracy, and the chief advantage which the generality of prætors looked for from the office. Cicero had no love of money, nor genius for arms, fo that thofe governments had no charms for him. The glory which he purfued was to fhine in the eyes of the city, as the guardian of its laws, and to teach the magiftrates how to execute, and the citizens how to obey them.

But the great object of all his hopes was the confulfhip, to fue for which he now began to prepare; and his chief folicitude was to obtain it in its proper year, and without a repulfe. The affection of the city, fo fignally declared for him in all the inferior fteps of honour, afforded him flattering hopes of fuccefs in his prefent pretenfions to the higheft: but he had reafon to apprehend great oppofition from the nobility, who looked upon the public dignities as a kind of birthright, and could not brook the claims of *new men;* and, therefore, he refolved to put it out of their power to fruftrate him, by taking the pains, required of a candidate, to vifit and folicit all the citizens in perfon. On the day of election, therefore, he mixed with the crowd, affembled in the field of Mars, careffing and familiarly faluting each individual by name. In the vacation from the forum, which was ufually in Auguft, he alfo vifited the towns and colonies of the Cifalpine Gaul, a province which, from its numerous votes, had great influence in the election. Amongft his competitors was the famous Catiline, now returned from the government of Africa, where, to fupply his boundlefs extravagance, he had practifed rapine and extortion. In order to defeat the claims of this formidable rival, the friends of Cicero appear to have prefented againft him the charge of mal-adminiftration, and hence in a letter to his friend Atticus he thus expreffes himfelf: "As to Catiline, I am then only fure of him as a competitor, when his judges fhall decide that the fun never fhines at noon day." It was ufual with the Roman lawyers to defend the moft infamous criminals, if recommended by birth and fortune. Of this practice Cicero expreffes his repeated difapprobation; yet we find that his principles, however fair and honourable, when they interfered with his intereft, in any affair of moment, were facrificed to his ambition. Catiline applied to our orator to fhield him by his eloquence, from the vengeance of the law. The refult of this unexpected application we learn from a fubfequent letter to Atticus; "I am now," writes he, "preparing to defend my competitor Catiline. If he fhould be acquitted, I am in hopes that he will the more cordially concur in promoting my election; but if it fhould prove otherwife, I fhall endeavour to bear it with patience." Yet in a fpeech which fome time after he made againft the criminal, he addreffes him, "Wretch, not to fee, that thou art not acquitted, but referved only to a feparate trial, and heavier punifhment."

As the election of confuls approached, Cicero's intereft appeared to be fuperior to that of all the candidates: for the nobles themfelves, though always envious and defirous to deprefs him, yet, out of regard to the dangers which threatened the city from many quarters, began to think him the only man qualified to preferve the republic, and to break the cabals of the defperate by the vigour and prudence of his adminiftration. The method of choofing confuls was not by open votes, but by *ballots*, or little tickets of wood, diftributed to the citizens, with the names of the candidates feverally infcribed upon each: but in the cafe of Cicero, the people were not content with this fecret way of teftifying their inclinations, but before they came to any fcrutiny, loudly and univerfally proclaimed Cicero the firft conful, fo that, as he himfelf declares, in his fpeech after the election, "he was not chofen by the votes of particular citizens, but the common fuffrage of the city, not declared by the voice of the crier, but of the whole Roman people." He was the only new man, who had obtained this fovereign dignity, or, as he expreffes it, "had forced the entrenchments of the nobility for forty years paft, and the only one who obtained it in its proper year, and without a repulfe."

Cicero, being thus arrived at the higheft honour, which a citizen could defire, or the people beftow, employed his talents with extraordinary fuccefs in adminiftering the affairs of the republic; and, according to the unanimous teftimony of all ancient writers, Rome never ftood in greater need of the fkill and vigilance of an able conful than in this very year. His firft policy was to conciliate his colleague Antonius, by affigning to him the beft province, at the expiration of their year; and having by this facrifice fecured his concurrence, he made it the firft object of his adminiftration to unite the equeftrian order with the fenate; and it was the authority of his confulfhip that firft diftinguifhed and eftablifhed the former into a third order of the ftate. About the time of his inauguration, the tribune P. Servilius Rullus propofed to the fenate an *agrarian law*, the object of which was to appoint ten commiffioners, with abfolute power for five years, over the revenues and lands of the republic. The promulgation of a law fo pernicious, however gratifying to the populace, the new conful oppofed; and in a fpeech delivered from the roftra, he gave fuch a turn to the inclination of the people, that they rejected it with as much eagernefs, as they had before evinced to receive it; affuring them of his fixed determination not to fuffer the ftate to be injured, or its liberties impaired, while the adminiftration continued

tinued in his hands. This was a ftriking inftance of the influence which his eloquence obtained over the paffions of men; and the following is a ftill more memorable proof of his afcendancy in fwaying the public mind. Otho, who had propofed a law for the affignment of feparate feats to the equeftrian order, appearing foon after in the theatre, was univerfally hiffed by the people, while from the knights he received the loudeft applaufe. A tumult enfued, and Cicero, informed of it, repaired to the theatre, and the confequence of his addrefs was, that the people vied with the knights in applauding the man whom they before had hiffed; and it is fuppofed, not without fome colour of truth, that the conduct of Cicero on this occafion gave birth to the beautiful comparifon of Virgil in Æn. i. 152. 157. About this time, a formidable confpiracy was formed in the bofom of the republic: of this the chief author was Catiline, and with him concurred a number of young men of diftinction, who had facrificed their fame to their vices, and who fought to repair their ruined fortunes by the diforders of the ftate. The conful detected and defeated their plans, and claimed, by his fuccefs, the proud appellation of the faviour of his country. See the article CATILINE. In this year was born *Octavius*, firnamed Auguftus, an event, which, though infignificant in itfelf, ferved by a concurrence of aufpicious circumftances to open a new æra in the annals of Rome: and it has been noticed as an inftance of the infcrutable ways of Providence, and the fhort-fighted policy of man, that, in the very year in which Cicero faved the republic from deftruction, appeared an infant, who in a fhort time effected what Catiline had in vain attempted, and deftroyed both Cicero and the republic. Having attained the pinnacle of public honours, he did not derive from his elevation that fame, influence, and popularity, which he expected to enjoy. At the expiration of his office, he defired no foreign government, no command of armies; his province was the fenate and the forum; for the purpofe of guarding, as it were, the palladium of the empire, and directing all its counfels to their proper end, the general good; and in the advanced poft of a *confular fenator*, the character which he chiefly coveted, as in a watch tower of the ftate, to obferve each threatening cloud and rifing ftorm, and to give the alarm to his fellow citizens from what quarter it was coming, and by what means its effects might be prevented. In this honourable ftation he excited the envy of the nobles, and the malignity of the profligate: and the fplendour of the nobleft conful whom Rome ever beheld, was foon followed by the difgrace of a voluntary banifhment. The caufes which more immediately led to this extraordinary event, claim, from their importance, a place in this narrative.

About this time J. Cæfar returned from the government of Spain, and Pompey from the Eaft, both celebrated by their far-famed victories. The former fought the confulfhip, while the latter endeavoured to obtain of the fenate the honour of a triumph: but not fucceeding to the extent of their ambitious views, they united with L. Craffus, a rich and turbulent citizen, who hoped to raife himfelf by the authority of Pompey and the talents of Cæfar. The object of this coalition, which was called the *firft triumvirate*, and which terminated in the diffolution of the republic, was to extort that power by violence and bribery which was denied by law, and as a neceffary ftep to this end, to detach Cicero, the bulwark of the ftate, from the intereft of the fenate. In the mean while P. Clodius, a young man of noble birth, and great talents, but of abandoned morals, had an intrigue with Pompeia, Cæfar's wife. But, as he could not eafily gain accefs to her, he took the opportunity, while fhe was celebrating the myfteries of the goddefs *Bona Dea* at her own houfe, to enter difguifed in a woman's habit. While he was waiting in one of the apartments for Pompeia, he was difcovered by a maid-fervant of Cæfar's mother, who immediately giving the alarm, he was driven from this female fociety with great indignation. The ftory was prefently known, and excited general abhorrence on account of the profanation of rites held the moft facred. The citizens and the priefts demanded the punifhment of this bold impiety, and Cicero, concealing fome political motives under the veil of religion, took the lead in the profecution. It was the conftant belief of the populace, fays he, "that if any man fhould ever pry into thefe myfteries, he would be inftantly ftruck blind. But it was not poffible to know the truth of it before, fince no man befides Clodius was bafe enough to make the experiment; though it was now difcovered that the blindnefs of the eyes was converted to that of the mind." Clodius, though fo obvioufly guilty, as, in the words of Hortenfius, to be deftroyed with a fword of lead, was yet acquitted by his corrupt judges; and to revenge the chief author of the profecution, he adopted effectual means for his deftruction. Cæfar and Pompey, in order to remove the chief obftacle to their ambition, and to render dependent upon them the illuftrious object of their envy, though profeffedly friends to Cicero, yet in reality concurred in the faction againft him, and by the adoption of Clodius, a nobleman, and therefore by birth incapable of being elected tribune of the people, into a plebeian family, caufed him to be invefted with that office. In this capacity, in order to gain the public favour, and to humble his rival, he promulgated many laws, which, as they were advantageous to the people, Cicero was advifed not to oppofe. By thefe means, in which he difplayed talents and perfeverance worthy of a better caufe, Clodius unravelled the grand plot of the play he was acting, obtaining a fpecial law, that whoever had taken the life of a citizen uncondemned, and without a trial, fhould be prohibited from fire and water. Cicero, though not named, was known to be the perfon intended by the law. His reputed crime was the putting Catiline's accomplices to death, which, though not done by his fingle authority, but by a general vote of the fenate, was alleged to be illegal, and contrary to the liberties of the people. Thus reduced to the condition of a criminal, Cicero changed *his habit*, as was ufual in the cafe of a public impeachment, and appeared about the ftreets in a fordid mourning gown, to excite the compaffion of the citizens; whilft Clodius, at the head of his mob, contrived in feveral places to meet and infult him, reproaching him with cowardice, and pelting him with ftones. But he was refcued from danger, though not protected from infults, by the zeal of his friends. The whole body of the knights, the young nobility to the number of twenty thoufand, and the greater part of the citizens changed their habits, and attended him about the city to implore the protection and affiftance of the people. But thefe humiliating meafures were premature, and the faction gained, from the dejection and precipitate fears of Cicero, that triumph which it would have loft by a more manly and determined oppofition. His enemies by their fuccefsful attacks increafed in number and ftrength. The tribune Metellus, the confuls, Pifo and Gabinius, were among his open foes. Cæfar, though unfeen, was the principal agent in the plot, and the protection of Pompey was implored in vain. In this extremity he fummoned a council of his friends with intent to act agreeable to their advice; and propofed the queftion, Whether it was beft to ftay in the city, and defend himfelf by force, or to prevent the effufion of blood by retreating till the ftorm fhould be over? Lucullus advifed the firft, but Cato and Hortenfius warmly urged the laft expedient, which, fanctioned by the authority of Atticus, and the entreaties of his

family,

family, induced him to leave the field in the possession of his enemies, and submit to a voluntary exile. The mind of Cicero, however elevated by superior genius, was, in seasons of danger, abject, timid, and undetermined. He wished indeed to prevent the effusion of blood, but there is reason to believe that the blood which by his precipitate retreat he desired principally not to shed, was his *own:* and when the hardships of banishment rendered him sensible of his cowardice, he bitterly reproached himself, in his letters to Terentia and Atticus, for not having taken up arms, and resolutely withstood the violence of Clodius. With his prosperity Cicero lost his dignity, and there is no period of his life in which his character appears less respectable than in his afflictions. The letters which he addressed to his friends, and which convey the only knowledge we have of him during his banishment, are filled with bitter complaints of the insincerity of his friends, his own misconduct, and regret that he did not put an end to his life. "Your advice," says he, in one of his letters to Atticus, "has restrained me from doing violence to myself. But your encouragements have not been able to reconcile me to the course I have followed, and to the life I lead. For what is there for which I should now desire to live, especially if I am disappointed in the hopes I carried with me out of Rome. I will not, indeed I will not, recount all the miseries into which I have fallen, through the unexampled wickedness of the men who envied, rather than of those who hated me, lest I should awake to all the horrors of my condition, and you to a sense of my sorrows. One thing I affirm, never was a man oppressed with such a weight of calamity; never had a man more reason to implore death. But the time is irrecoverably past, when I might have died with glory. The remainder of my days cannot repair, they can only finish my miseries." His friend used every means to console and support him, reproves his abject lamentations, and expresses his apprehensions that his understanding was impaired by excessive grief. To this he replies, "You often accuse me with being too much dejected under my misfortunes; but you ought to forgive me this weakness: for you never saw, you never heard, of any so distressed as I am. You tell me that my sufferings have affected my understanding. This is not true; and I wish my judgment had been equally clear and sound at the time I united with those hostile and cruel traitors, whom I imagined to be the best friends to my person and welfare; those who, when they saw me indisposed from apprehension to accord with their views, had recourse to all the arts of perfidy as means to effect my ruin." Lib. iii. 14.

In the mean time Clodius proceeded against him with unabated fury, caused a law to pass that no one should receive him, or make any motion for recalling him, under pain of death, plundered his magnificent villas, and, after destroying his house in Rome, consecrated the spot to the perpetual service of religion, and upon it built a temple to the goddess Liberty. Emboldened by these successes, he now began to act without the consent of, and even in opposition to, his chief supporters. The implacable resentment of Clodius towards a fallen adversary, or the dread of his power, now grown formidable, induced Pompey at length to espouse the cause of Cicero; but unwilling to take any step for his restoration, without the concurrence of Cæsar, he sent Sextius with dispatches to Spain to solicit his consent and influence. Metellus, now advanced to the consulship, from fear of offending Pompey, no longer acted with open hostility, and Lentulus, his colleague, was the active and decided friend of Cicero. Vigorous, though indirect and partial, measures were now adopted to effect his recal. The honest citizens were invited to Rome from all parts of Italy, and entertained with public shows. The senators held him upon all public occasions as the saviour of their country; plays were acted with pointed reference to the illustrious exile, and the tragedian Æsopus, in the character of the banished Telamon, was received with enthusiastic applause. After repeated efforts, defeated by the skill and vigilance of Clodius, the law for his restoration was ratified, in the most numerous assembly of citizens which Rome ever contained: and this ratification was probably the last act of justice and freedom, which the republic ever exercised.

The day of his return to Rome was the 4th of August, after an inglorious absence of 18 months. As he approached the city, multitudes from all parts flocked to see and to congratulate him. All the towns of Italy decreed him public honours, and sent him a deputation of their chiefs to testify their joy at his return, and it has been emphatically said of him by Plutarch, that he was carried back upon the shoulders of Italy. "That one day," says he, "was worth an immortality, when, on my approach towards the city, the senate came out to receive me followed by the whole body of the citizens, as if Rome itself had left its foundations, and marched forward to embrace its preserver."

His first act, after being restored to his rank, though not to his property, was, in eloquent and affecting speeches to thank the senate and the people for the active part which they took in his restoration. Gratitude in the heart of Cicero was a principle of refined sensibility, which knew no restraint from reason, or any limitation from the duties, which he owed to the interests of the Republic. To Lentulus, now governor of Cilicia, he evinced his sense of obligation by endeavouring with unwearied efforts to authorise him, with the consent of the senate, to restore Ptolemy, a profligate and cruel prince, to the throne of Egypt. The great concourse of citizens in Rome from the different parts of Italy, had occasioned a temporary scarcity, which was severely felt by the common people: and in order to restore plenty to the city, he proposed that Pompey should be invested with an absolute power over all the public stores of the empire. The motion passed into a law; and Pompey was authorised for five years to superintend all the provisions of the Republic, with the power of choosing fifteen officers to act as his deputies. Cæsar, who was now in the full career of victory in Gaul, sent the senate a request that money might be decreed him for the payment of his army, and his command be prolonged five years more. The demand, though exorbitant, was supported by Cicero, who alleged that the course of his victories ought not to be checked by the want of necessary supplies, while he was so gloriously extending the bounds of the empire, and conquering nations, whose names had never before been heard at Rome. His object no doubt was to conciliate Cæsar, and more fully to evince his devotion to Pompey. But his conduct was an evident deviation from his own principles; and the patriots, his former friends, charged him with apostacy, who, with Cato at their head, appear now to have formed a party against him. In a letter addressed to the pro-consul Lentulus, he justifies himself with great ingenuity and elegance. "It appears to me," says he, "to be the dictate of sound policy, to act in accommodation to particular conjunctures, and not inflexibly to pursue the same unalterable scheme, when public circumstances, together with the sentiments of the best and wisest members of the community, are evidently changed. In conformity to this notion, the most judicious reasoners on the great art of government have universally condemned an obstinate perseverance in one uniform tenor of measures. The skill of the pilot is shewn in weathering the storm at least, though he should not gain his port, but if shifting his sails, and changing his direction, ſhould infallibly carry him with ſecurity into the intended harbour, would it not be an inſtance of moſt unreaſonable tenaciouſneſs to continue in the more hazardous courſe, wherein he began his voyage? Thus (and it is a maxim I have often had occaſion to inculcate) the point we ought all of us to keep in view in our adminiſtration of the commonwealth, is the final enjoyment of an honourable repoſe. But the method of ſecuring to ourſelves this dignity of retreat, is by having been invariable in our intentions for the public welfare, and not by a poſitive perſeverance in certain favourite modes of obtaining it. To repeat, therefore, what I juſt now declared, had I been abſolutely uninfluenced by every motive of friendſhip, I ſhould ſtill have purſued the ſame public meaſures in which I am now engaged. But when gratitude and reſentment both conſpire in recommending this ſcheme of action to me, I cannot heſitate a moment in adopting it, eſpecially ſince it appears moſt conducive to the intereſts of the republic in general, as well as to my own in particular. To ſpeak freely, I act upon this principle, ſo much the more frequently and with the leſs reſerve, not only as my brother is lieutenant under Cæſar, but as the latter receives the ſlighteſt action or even word of him in his favour with an air, that evidently ſhews he conſiders them as obligations of the moſt ſenſible kind. And, in fact, I derive the ſame benefit from that popularity and power which you know he poſſeſſes, as if they were ſo many advantages of my own. The ſum of the whole in ſhort is this, I imagined that I had no other method of counteracting thoſe perfidious deſigns, with which a certain party were ſecretly contriving to undermine me, than by thus uniting the friendſhip and protection of the men in power, with thoſe internal aids which have never yet been wanting to my ſupport." With equal ſeverity and truth it has been remarked, that the principles by which Cicero attempts to juſtify himſelf in this epiſtle are ſuch as will equally defend the moſt abandoned proſtitution and deſertion in political conduct. Perſonal gratitude and reſentment; an eye to private and particular intereſt, mixed with a pretended regard to the public good; an attention to a brother's advancement and farther favour; a ſenſibility on being careſſed by a great man in power; a calculation of the advantages, derived from the popularity and credit of that great man to one's own perſonal intereſt, are very weak foundations indeed to ſupport the ſuperſtructure of a true patriot's character. Yet theſe are the principles which Cicero here avows and defends.

The ambitious chiefs, Pompey and Cæſar, whoſe union was cemented only by views of intereſt, began at length to be at variance; an event accelerated by the death of Julia, who was tenderly beloved by both. The ſenate, in general, were in the intereſt of Pompey, who, confiding in the name and authority of ſo great a leader, were determined to humble the pride and ambition of his rival, by re-calling him from his government; whilſt Cæſar, on the other hand, relying on the fidelity of his troops, reſolved to keep poſſeſſion of his power, in defiance of the ſenate. This was the commencement of the civil war, which terminated in the deſtruction of the commonwealth, and in the final misfortunes of Cicero. In this poſture of affairs, Cicero was induced to accept the government of Cilicia, a character which he never before ſuſtained, and which he was anxious to decline, or, at leaſt, not to prolong, though in the eſtimation of reaſon it comprehends the moſt honourable period of his life. He formed the generous reſolution of practiſing in his provincial command thoſe admirable rules which he had previouſly drawn up for his brother, and from an employment to which he ſeems totally averſe, of gaining freſh acquiſition of glory and ſatisfaction, by leaving his adminiſtration as a model of juſtice and integrity to all ſucceeding proconſuls. To his friend Atticus, he tranſmitted a minute account of his proceedings, and it would be injuſtice to his memory not to make a ſhort extract of his detail. "I perceive that my moderation and diſintereſtedneſs give you pleaſure; but how would it be enhanced, had you been here in perſon? Many cities had the whole of their debts cancelled; many were greatly relieved, while all of them, being judged by their own laws and in their own forms, recovered their ſpirits by thus recovering their conſtitution. I have given thoſe cities a power of keeping themſelves free of debt, or making their debts very eaſy by two means; the one, that, during the whole time of my government, I have not put them, and I ſpeak without a figure, to one farthing of expence, I repeat it, not to a ſingle farthing. It is incredible how many cities have diſcharged their debts from this ſingle circumſtance. The other mean was the following: They were greatly plundered by thoſe among the natives, who, for ten years paſt, had been their magiſtrates, and who did not ſcruple to acknowledge the fact; and, therefore, to prevent a public cenſure, with their own hands returned the money to the people. By theſe means, the ſubjects, without any difficulty, have paid to our farmers of the revenue all the land tax for this term, of which, till then, they paid nothing, and their arrears of the laſt. In all the other departments of my government, I proceeded with ſimilar addreſs, and my clemency has been joined to unexampled affability. In giving my audiences, I have laid aſide the formalities adopted by other provincial governors. I ſuffer no application to be made to my dependents, but directly to myſelf. Before day-break, I walk about in my houſe, as I uſed formerly to do, when I ſtood for public offices. This condeſcenſion ſecures me popularity and influence, and I was formerly ſo accuſtomed to it, that it gives me as yet no pain." How many millions of human beings would have been rendered happy if all the governors of the provinces could, with equal truth, have given a ſimilar account of their adminiſtration! His conduct in this, as well as in many other reſpects, proves that Cicero was naturally diſpoſed to be on the ſide of the people, and a foe to oppreſſion; that he delighted in acts of juſtice and beneficence, and that, however deſirous of diſtinction, he had more pleaſure in communicating happineſs to others than in accumulating to an immoderate extent the means of happineſs to himſelf; and that he never deviated from the true intereſts of his country, or ſupported the claims of ambition, but when allured by the ſplendid accompliſhments, or aided by the high authority, of the claimants. As a commander, he made a leſs enviable figure. Nature did not intend Cicero for a ſoldier; yet, by ſome ſucceſsful movements againſt the Parthians, and ſome advantages over the inhabitants of Mount Amanus, and of the town Pandeniſſum (a name which, however ſtrange to Atticus, meant only *a city on the hill*, and conveys the ſame meaning with Penthinas in Celtic, or Βουνουδιναξια in Greek), he received the title of "Imperator," and returned home with laurelled lictors, claiming the honour of a triumph, and ſoliciting a decree of *thankſgiving*. When the queſtion for this decree was diſcuſſed in the ſenate, Cato roſe and expreſſed his opinion, that the military achievements of the commander little deſerved notice, but that his diſintereſted conduct as a governor was ſuch, that if triumph were decreed to virtues as well as to victories, he merited a thouſand. Of this fine compliment, beſtowed by ſo great a man, Cicero was in-

formed,

formed, and he thus fpeaks of it to Atticus; "The man who oppofed that meafure did me more honour than triumphs can beftow."

The civil war, the fparks of which began to appear before his departure, was now fully kindled on his return to Rome; and the firft wifh of his heart was to extinguifh the flame between the contending parties, thinking, as he himfelf expreffes it, that "peace between citizens, however unfavourable the terms, was more advantageous than the moft juftifiable war." But his hopes of accommodation, while Cæfar folicited his interference for that purpofe, were fruftrated by the ftubbornnefs of Pompey, who expreffed his determination either to conquer or to die in the caufe of liberty, though he afterwards acted with a precipitation which forfeited all confidence either in his fkill or his courage. Supported as he was by the fenate, the patriots, by all the virtuous citizens and the united forces of the republic, he left Italy with its municipal towns, Rome with all its treafures, to be the prey of Cæfar, which he feized with the rapacity and fwiftnefs of a vulture. His unaccountable conduct in this refpect induced him to charge Pompey with inability; and regarding him as one who had been guilty of failing out of harbour without a rudder, and committing himfelf to the mercy of the ftorm, he long hefitated to follow him beyond fea. Yet he was too much attached from gratitude and from principle to the caufe of Pompey, however he might waver, finally to abandon it. This leader, indeed, Cicero knew was tyrannical in his views, and too prone to imitate the profcriptions of Sylla; but, upon the whole, he confidered him as the champion of public liberty, or, at leaft, the country had lefs to dread from his cruelties than from the ambition of his rival. On the other hand, Cæfar he confidered as a bold defperate citizen, who wifhed to fubvert the civil conftitution, and to accumulate in himfelf the whole powers of the ftate. "Poffeffed," fays he to Atticus, "of a powerful army, multitudes joining him from hopes and promifes: his ambition grafps every object. Such is the man to whom Rome, deprived of the means of defence, but ftored with riches, has been furrendered. What have we not to apprehend from one who looks upon Rome, with all her edifices, public and private, not as his country but his prey? Miftaken wretched man! infenfible to every idea of true glory! He pretends that all he does is to maintain his dignity. But can dignity exift without virtue? Is it compatible with virtue to continue at the head of his army, without the voice of the people to authorize him, and to feize cities inhabited by Romans, that he may open to himfelf a more eafy paffage to the heart of his country? Not to mention the cancelling of the national debts, the recal of the banifhed, and a thoufand crimes that are yet to be perpetrated, before he can rear the temple of tyrannic power, the only deity he worfhips. I do not envy his greatnefs. I had rather fpend one day with you in the funny walks of Lucretum, than be a monarch over innumerable kingdoms acquired by guilt like his. I had rather die a thoufand deaths than harbour fuch an idea at the expence of my country. You think, you will fay, for yourfelf. And is there a wretch who is not at liberty to think? But I repeat it, I think the man who acts in this manner is more miferable than the wretch who lies extended on the wheel. There is but one mifery beyond it, and that is fucceeding in the attempt."

Thefe fentiments have their proper place affigned them in the Cato of Addifon, but are too much coloured by paffion to correfpond with the real features of truth; and in the letters which he fent to Cæfar, he fpeaks of him in terms fo different, that they brought upon him the imputation of adulation and fervility. Contrary to the general apprehenfion, Cæfar behaved with uncommon clemency; and Cicero himfelf, notwithftanding his petulance, experienced his forbearance. Having triumphed over Italy by his humanity, he, about a year after, defeated his rival at Pharfalia. Cicero was not prefent at the battle, having, from indifpofition or chagrin, ftayed behind at Dyrrhachium. He refolved to give the ufurper no farther oppofition, but to devote, in retirement, the remainder of his days to letters and philofophy. He was advifed by Atticus to addrefs an epiftle to Cæfar, in commendation of his clemency and his military achievements, directing him, at the fame time, in the ufe of his victories and the adminiftration of the empire. This letter was compofed, but, for fear of giving offence to fome of Cæfar's dependents, was never fent. It appears to have been written in a ftyle of uncommon elegance, and the manly freedom with which he addreffed the tyrant, would, if preferved, have reflected great honour on his memory. What he fays to Atticus in refpect to it is well deferving of being tranfcribed; "You are no ftranger to thofe perfuafive addreffes which were made to Alexander by men of eloquence and learning. They addreffed a young prince, fired with the love of the trueft glory, and panting for thofe counfels which lead to the fummit of unperifhable fame. Eloquence is not wanting, when it is infpired by a fubject truly glorious. This in Cæfar I do not poffefs. Neverthelefs, from the untowardly materials of the oak, I have carved, if not the image of true glory, yet fomething that bears the refemblance of it, and becaufe fome features in it are wrought with more exactnefs than thofe ufually delineated, they are cenfured."

He rejoiced in the affaffination of Cæfar by Brutus and Caffius, though he had no previous knowledge of the confpiracy. The hope of faving the country induced him again to take an active part in public affairs, and by his eloquence and authority he prevented Antony from fucceeding to the empire. But betrayed by Octavius, whofe caufe he had efpoufed, he was delivered up to the vengeance of his rival. The triumvirs agreed to divide the empire among themfelves, and to place Cicero at the head of the profcription. This at firft was kept a fecret; but before it tranfpired, it was confidentially imparted to him while with his brother and nephew at his Tufcan villa. He firft fled towards Aftura, with the intent of croffing the fea, but after embarking, the wind proving contrary, and the fea tempeftuous, he landed at Circæum, in order to repofe in his Formian villa, weary of life, and declaring that he would die in that country which he had fo often faved. His fervants, anxious for his prefervation, prevailed upon him to be conveyed away in the morning. As foon as he was gone, the foldiers fent in purfuit of him, arrived at the houfe, and perceiving that he was fled, they haftened towards the fea-coaft, and overtook him in a wood, where they cut off his head and hands, and in triumph returned with them towards Rome. Antony ordered the head to be fixed on the roftra between the two hands, and rewarded Popilius, the leader of the foldiers, with the honour of a civic crown, and the fum of eight thoufand pounds. The whole city lamented the cruel fate of this eminent man, and wept at the fight of thofe members, once glorioufly exerted in defence of the laws, the liberties, and the fortunes of the Roman people, but now ignominioufly expofed in that very place, to the fcorn of fycophants and traitors. His death occafioned univerfal forrow; it was confidered as the final triumph of defpotifm, and his blood as cementing the perpetual flavery of Rome. The writers of the Auguftan age have paffed over this cruel deed with inglorious filence, and fought to draw over the cruelty of of Antony and the perfidy of Octavius, the veil of eternal oblivion. Yet Paterculus could not refrain from the following beautiful expostulation: "Thou hast done nothing, Antony; hast done nothing, I say, by setting a price on that divine and illustrious head, and by a detestable reward procuring the death of so great a consul and preserver of the republic. Thou hast snatched from Cicero a troublesome being, a declining age, a life more miserable under thy dominion than life itself; but so far from diminishing, thou hast but increased the glory of his deeds and sayings. He lives, and will live, in the memory of all ages; and as long as this system of nature, whether formed by chance or providence, which he of all others best comprehended in his mind, and illustrated by his eloquence, shall remain unchanged, it will perpetuate the praises of Cicero; and posterity, while they will admire his writings against thee, will curse thy deed against him."

About the time of his consulship Cicero married Terentia, a lady of family and fortune, who shared in the trials of his banishment with great firmness, and whom he then appears to have tenderly loved, but whom for some domestic grievance, at which he delicately hints in a letter to Atticus, he afterwards divorced. By Terentia he had a son and a daughter. The son, with all the advantages of education and example, inherited neither the talents nor the virtues of his father; but the daughter, as she merited, possessed in an eminent degree his affections. She was first married to Piso, a young nobleman of great promise; but being left a widow in the bloom of youth, she again married Crassipes, and afterwards Dolabella, from whom, without any imputation on her chastity and honour, she was successively divorced. She died of child-birth in the thirty-second year of her age. Her father's grief was excessive. Retired from the world, and secluded even from his friends, he adopted the singular expedient of addressing to himself letters of consolation, and we owe to his seclusion at that period, many of those philosophical treatises, which have since delighted and instructed the world. Thinking her deserving of immortality, he had the weakness to seek her deification on earth, by erecting a temple in memory of her name and worth. Cicero believed the immortality of the human soul; but on the absurd principle derived originally from the Chaldeans, that, being a particle of the deity, and existing previously to the present, it would continue to exist in a future state. A faith thus borrowed from superstition, and unsupported by the force of truth, could have little effect upon his conduct, and he seems to have derived no comfort from the hope of being again restored to his beloved offspring. In a letter to Atticus respecting the death of a common friend, he urges the consolatory maxim, that "we are born on the condition of submitting to all the calamities entailed on our nature." But this sentiment, however beautiful, is calculated rather to silence than to soothe complaint; and yet this is the farthest limit to which the light of natural religion extends. The disciple of nature under affliction may cease to grieve, because to grieve is unavailing; because the cause of his sorrows is the inevitable lot of man. But the believer in revelation possesses sources of real consolation even in circumstances of the greatest distress. Deprived of his dearest friends and relatives, and even in the prospect of his own death, he looks through the evidences of christianity to a renewed and more exalted being. His fears therefore are changed into resignation, and his sorrows subside into serenity and joy.

The person of Cicero was tall and slender, with a long neck, but regular and manly features. His deportment was dignified and commanding, yet enlivened by cheerfulness and serenity. Though naturally weak, his constitution was made capable, by habit and discipline, of supporting all the fatigues of action and of study; while his moderation in respect to diet, with regular exercise, insured him perpetual health and vigour. His temper was open and communicative; his attachments, domestic and social, were warm and violent, but liable to change or abate with the change of objects or situation. While his connection with Atticus taught and exemplified the principle of genuine friendship, his frequent reconciliation, and even exertion in behalf of those who had been his bitterest enemies, prove that he possessed a forgiving and placable heart. His manner was free from the affectation of singularity; and in his dress he avoided the opposite extremes of rustic negligence and foppish delicacy. His villas, his gardens, and his studies were highly magnificent, adorned with the most valuable monuments of art, and the most expensive articles of furniture. The style of living, which he conceived suitable to his rank, and of entertaining his friends, was liberal to profusion. He seemed to think that money, with whatever toils acquired, should be chiefly spent by a man of rank, in the gratification of taste. The want of economy and attention to his domestic affairs, sometimes occasioned embarrassment to himself and losses to his friends; and he, whose talents enabled him to lay the whole community under tribute, was often under pecuniary obligations to inferior or obscure individuals. But his predominant failing was vanity. He knew the extent of his own powers; he felt the high estimation in which he was held as a scholar, an orator, and a statesman; he was sensible of the favours which his knowledge or his eloquence had conferred upon the public, and no commendation that might appear inadequate to the extent of his merits, could satisfy his appetite for praise. The parade with which he often speaks of his conduct in the republic, or in the government of Cilicia; the frankness, with which he extols the eloquence of his own compositions, or the effects of his speeches, his request to Lucceius to write the annals of his consulship, and to praise him, even at the expence of truth, are unfortunately still recorded to perpetuate his weakness. But these imperfections, though they might detract from the dignity, did not impair the moral excellence of his character. Few persons in christian countries, and none in his own age, were upon the whole so free from vice. He was an entire stranger to the sordid passions of lust and avarice; and however vain, irresolute, or inconsistent a part he sometimes acted, he does not appear ever to have committed a crime. His candour in the various relations of life exemplified the lessons of morality which his writings inculcate; and they are unquestionably the best and purest of which heathen antiquity can boast.

His character as an orator and philosopher is too well known to need a minute delineation. His powers of writing and speaking shone with unrivalled lustre; and his name soon became synonymous with that of eloquence. According to the unanimous opinion of critics, he possessed in an eminent degree the qualities of a fine speaker, a powerful voice, a commanding figure, graceful action, a brilliant imagination, a happy turn for wit and raillery, a correct taste, and a sound judgment: with a memory retentive and enriched with all the possible varieties of knowledge, which incessant study, active curiosity, conversation with the learned, and acquaintance with books could supply. With these endowments he soon rose above all competition. At the commencement of his judicial career, he eclipsed the famed Hortensius; and in the meridian of his glory, the forum and the senate served but as a throne to raise him above others, and to display to the view, not only of the empire, but of of surrounding nations and distant ages, the royalty and magnificence of his genius. It was his chief ambition, as he profited by the example, to rival the fame of Demosthenes; and if he did not possess the fire and energy of the Greek orator, he surpassed him in readiness of elocution, in the harmony of his periods, and in the richness and variety of his sentiments. With all the predilection of taste, even in modern days, his style however is not deemed perfect; and he appears to have been disapproved by his contemporaries, Brutus and Varro, as well as his admired critic Quintilian, for the technical uniformity of his arrangements, his frequently frigid attempts at wit, for the exuberance of his fancy, and the diffuseness of his sentiments.

As a philosopher, he may be said to have been a disciple and imitator of Plato, whom he admired to enthusiasm, and to whose dignified style and enlarged principles, he acknowledged himself more indebted than to the artificial rules of rhetoric. In his scientific disquisitions, he avoids the rigour of the stoics, and the uncertainty of the sceptics; and against the Epicureans, he maintains the existence of a supreme being; the doctrine of a providence; the immortality of the human soul; and the natural, immutable difference between good and evil. But these important principles he adopted, rather on the authority of the academy, as consonant with reason and virtue, than as the result of his own inquiry, and brought home to his conviction by irrefragable argument. We cannot therefore wonder, that, however they might amuse his understanding, they had little influence on his heart, or that he should have been more successful in demolishing the opinions of his adversaries, than in defining or establishing his own. Cicero was the first Roman, Lucretius excepted, who discussed, in Latin, the philosophy of Greece; and the several treatises which issued from his pen on that subject enriched the language, and enlarged the ideas of his countrymen. Of Grecian literature in all its branches, he had a profound and extensive knowledge. The perspicuity with which he states the tenets of the respective schools, the frequency with which he quotes or alludes to passages in their philosophers, orators, and poets, prove that their writings had not only passed through his hands, but were still retained in his memory. He could write and speak the Greek tongue with fluency; but some errors which he has committed, suggest a suspicion that his knowledge of it was more specious than solid, and that he was inferior in critical skill to his friend Atticus. See Tuscul. Disp. iv. 22. compar. with Dr. Clarke's note on Hom. Il. vi. 214. Guth. Translation of his Letters to Attic. b. xiii. 21, last edition. Many of his writings are lost; but those which remain, will preserve and endear his name, as long as literature is cultivated among men.

The works of Cicero, which are very numerous, have been commonly distributed into four classes, comprehending "Rhetorical Treatises," "Orations," "Philosophical Works," and "Epistles." Of the first class the most valuable are his three dialogues: "De Oratore," the art of oratory, addressed to his brother Quintus; his book "De Claris Oratoribus," on illustrious orators, entitled, "Brutus;" and his "Orator," the orator, addressed to Brutus. The number of "Orations" remaining under his name, amount to fifty-six; and whilst they comprehend the whole of his public life, they contain a treasure not only of eloquence, but of other matters pertaining to history and jurisprudence. The matter of his "Philosophical Works" was borrowed from the Grecian school; of these, the principal that treat of the philosophy of nature are "De Natura Deorum," a dialogue eloquently displaying the opinions of the Stoics and Epicureans, concerning the divine nature; "De Divinatione et Fato," exhibiting his superiority to the superstitions of his age and country; "Somnium Scipionis," founded on the Platonic doctrines, concerning the soul of the world, and the state of human souls after death. One of the most elaborate of Cicero's works that relate to moral philosophy is entitled "De Finibus," and discusses the opinions of the Grecian sects with regard to moral ends. His "Quæstiones Tusculanæ" treat of the contempt of pain and death, the remedies of grief and mental pertubation, and the sufficiency of virtue to a happy life. His treatise "De Officiis" is an excellent summary of practical ethics, chiefly upon the principles of the Stoics. His "Quæstiones Academicæ" contain his own opinions more directly than any other of his works. His dialogues entitled "Cato" and "Lælius" are very elegant pieces of moral writing. In his book "De Legibus" he explains the grounds of jurisprudence. His "Epistles," which are denominated "Familiar" with peculiar propriety, afford excellent specimens of the style adapted to such compositions, and abound with various matter, political and domestic. The suppression of Cicero's "Poetry" has done no injury to his reputation.

The editions of Cicero's works, whole or in part, have been very numerous; of the former, some of the best are Elzevir's, 10 vols. 12mo. L. Bat. 1642. Gronovii, 11 vols. 12mo. 2 vols. 4to. Amst. 1692. Verburgii, 16 vols. 8vo. 2 vols. fol. Amst. 1724. Oliveti, 9 vols. 4to. Paris, 1740. Ernesti, 6 vols. 8vo. Halæ. 1773—77. Lallemand, 14 vols. 12mo. Paris, 1768. Oxford, 10 vols. 4to. Of his separate works, all that have been edited by Grævius, Pearce, and Davis, merit recommendation. Most of his productions have been translated into various languages. Melmoth's versions of the "Epist. ad Familiares," and of the treatises on old age and friendship, are the best attempts of this kind in the English language. An improved edition of Guthrie's translation of Cicero's Epistles to Atticus, with many additional notes, by Mr. J. Jones, in 3 vols. appeared in 1806. Of the various lives of Cicero, that of Melmoth is the most complete, though it has too much the air of a continued panegyric or apology. Aikin's Gen. Biog.

Cicero, in *Geography*, a military township of America, in New York, on the S.W. side of Oneida lake, and between it, the Salt lake, and the Salt springs.

CICERONIASTRI, or Ciceroniani, in the *History of Literature*, an appellation given to those moderns who dispute the propriety of all expressions and words not found in Cicero. Such was the estimation in which the Roman orator was held as a writer, that his admirers will not allow that he was ever equalled; and, accordingly, they say of him that no sentiment occurs, in common with him and any other author, which is not best expressed by Cicero. Hence arose the enthusiasm excited by his works soon after the revival of literature, and the above-mentioned appellation.

CICERUM *lapis*, the *chich stone*, in *Natural History*, a name given by some authors to a sort of small round stones, of the nature of the pisolithe or pea-stones, but smaller than those usually are, and of a dusky grey colour. They very exactly resemble the fruit of the cicer or chich-pea, and are found in great abundance near the Old Jerusalem.

CICHALIX, in *Ancient Geography*, a mountain of Asia Minor, towards Bithynia.

CICHORACEÆ, in *Botany*, the first natural order in the tenth class of Jussieu, with the following character: *Florets* all strap-shaped and hermaphrodite, either entire or toothed

toothed at the tip. *Common calyx* of various forms. *Stigmas* two to each floret. *Seed* naked or downy. *Receptacle* naked or beset with hairs or chaff. *The whole plant* lactescent, herbaceous, often caulescent. *Leaves* alternate. *Flowers* generally yellow.

Jussieu has followed Vaillant in dividing this order into five sections, which, though not perfectly natural, he thinks useful, and therefore not to be discarded. 1. Receptacle naked; seed not downy; *lampsana*, *rhagadiolus*. 2. Receptacle naked; seed downy; down capillary; *prenanthes*, *chondrilla*, *lactuca*, *sonchus*, *hieracium*, *crepis*, *drepania*, *hedypnois*, *hyoseris*, *taraxacum*. 3. Receptacle naked; seeds downy, down feathery; *leontodon*, *picris*, *helmintia*, *scorzonera*, *tragopogon*, *urospermum*. 4. Receptacle chaffy or hairy; down feathery or capillary; *geropogon*, *hypochæris*, *seriola*, *andryala*. 5. Receptacle chaffy; down awned or none; *catananche*, *cichorium*, *scolymus*. Ventenat has adopted the above division, only adding arnoseris, which he has formed into a distinct genus for hyoseris minima of Linnæus, on account of its striated seeds, crowned with an erect, coriaceous, entire border.

CICHORIO *affinis*, Pluk. Amalth. tab. 380, fig. 2. See SIEGESBECKIA *orientalis*.

CICHORIUM, (κιχώρη and κιχώριον; Theophrast. lib. 7. cap. 7. and lib. 7. cap. 11.) It is said by Pliny to be an Egyptian name, adopted by the Greeks. It was sometimes written κιχόρειον, whence the

"Cichorea levesque Malvæ"

of Horace. The futile attempts of modern etymologists to derive it from the Greek are too contemptible to be noticed. Linn. Gen. 921. Schreb. 1251. Willd. 1427. Juss. 171. Vent. vol. ii. 492. Gært. 906. Tourn. Cl. 13. §. 2. Gen. 3. Chichorée; Lam. Encyc. Ill. Pl. 658. Class and order, *Syngenesia polygamia equalis*. Nat. ord. *Compositæ semiflosculosæ*, Linn. *Cinarocephalæ*, Juss.

Gen. Ch. *Cal.* calycled or composed of two ranks of scales; inner scales commonly about eight, narrow-lanceolate, forming a cylinder before the opening of the flower, reflexed as the seeds ripen; outer ones about five, short, loose. *Cor. compound*, flat, uniform; florets twenty in a ring, strap-shaped, deeply five-toothed. *Stam.* Filaments five; anthers united in a five-sided hollow cylinder. *Pist.* Germ oblong; style filiform, the length of the stamens; stigmas two, revolute. *Peric.* none. *Seeds* solitary, compressed, sharply angular, crowned with an obscurely five-toothed border, according to Linnæus. Gærtner asserts that it consists of many leaves, or chaff-like teeth, forming a kind of double series. *Recep.* somewhat chaffy.

Eff. Ch. Receptacle somewhat chaffy. Calyx calycled. Seed crowned with a chaffy border shorter than itself.

Sp. 1. Cichorium *Intybus*. Linn. Sp. Plant. Mart. Lam. Willd. Flor. Dan. tab. 907. Gært. tab. 157. Curt. Lond. Fasc. 4. tab. 56. Woodville, Supp. tab. 248. Eng. Bot. 539. (Cichorium sylvestre s. officinarum: Bauh. Pin. 125. Tourn. 479. Seris picris; Lob. Ic. 128. Intybus sylvestris, Fuchs. 979.) Wild succory. "Flowers in pairs, sessile. Leaves runcinate." Linn. *Root* perennial, spindle-shaped; running deep into the ground, often branched, white, fleshy, yielding a milky juice. *Stem* a foot and a half high and more, erect, stiff and firm, angular above, rough, leafy, except near the top, where it appears almost naked, many-flowered, branches divaricated. *Leaves* roughish; root ones runcinate; stem ones heart-shaped, embracing the stem, acuminate. *Flowers* axillary, in alternate pairs, large, handsome, blue, sometimes white; calyx-leaves with a rough keel, finally reflexed. *Receptacle* dotted, with a few scattered chaffy hairs. *Seeds* angular, crowned with a short border of chaff-like scales in a double series. Whole plant bitter. A native of England and other parts of Europe, on the borders of corn fields and by road sides, but most prevalent in a calcareous soil. When cultivated it is much more branched and rises to the height of five or six feet, with longer leaves, less deeply cut and almost smooth. It is then Cichorium sativum; Bauh. Pin. 125. Tourn. 479. Lob. Ic. 129. It certainly possesses considerable medical properties, though it has not obtained a place either in the London or Edinburgh pharmacopæas. Its virtues depend on its milky juice, which is of a penetrating bitterish taste, and of no remarkable smell or particular flavour; the roots are bitterer than the leaves or stalks, and these much more so than the flowers. The roots and leaves are stated by Lewis to be "very useful aperients, acting mildly and without irritation, tending rather to abate than increase heat, and which may therefore be given with safety in hectic and inflammatory cases. Taken freely, they keep the body open, or produce a gentle diarrhœa, and when thus continued for some time, have often proved salutary in beginning obstructions of the viscera, in jaundices, cachexies, hypochondriacal and other chronical disorders." "A decoction of it," adds Dr. Woodville, "with others of the same kind, in whey, and rendered purgative by a suitable addition of polychrest salt, has been found a useful remedy in cases of biliary calculi, and promises advantages in many complaints requiring what have been termed attenuants and resolvents; and we are warranted in saying, that its expressed juice taken in large quantities, has been found an efficacious remedy in phthisis and pulmonalis. Its seeds are reckoned among the four smaller cooling seeds." Med. Bot. The juice mixed with rhubarb, according to Du Tour, (Nouveau Dictionaire), is an excellent vermifuge syrup for children.

It was commonly eaten by the Romans, and, when blanched, is still used in France in soups or as a sallad, but little, if at all, in England, where C. endivia is preferred. If steeped some hours in water, the water being changed every two or three hours, it loses much of its bitterness. But this effect is more effectually produced by the operation of blanching, which leaves only so much bitterness as renders it not at all disagreeable. In Italy it has long been cultivated on a large scale, and esteemed, either green or dry, as an excellent fodder for horses, kine, and sheep. It was first introduced into France by Cretté de Pallael, and into England by the well-known Arthur Young, but the moist atmosphere of our island is less favourable to its being made into hay. The wild succory, says Du Tour, will grow in any kind of soil, but thrives best in a good one well manured, and is cultivated at a small expence. It sustains drought, excessive rains, and severe cold, and as it rises early in the year, affords an excellent spring supply. Its growth is so rapid, that it may be cut three or four times every year, or more frequently. Its produce in bulk and in weight is superior to that of trefoil and even of lucerne. There is no need of preparing cattle to use it as food; it is as wholesome as it is abundant, sweetens their blood, and preserves them from disease. In particular, it causes cows to give more milk without communicating any of its bitterness, and furnishes, eight months in the year, an excellent resource for the former, affording the first herbage for cutting in the spring, and the last in autumn. In Germany its dried powdered root is mixed with coffee, in the proportion of one third or a half, and is preferred to tea as more nutritious and much cheaper. 2. C. *pumilum*, Willd. Jacq. Obs. 4. p. 3. tab. 80. "Flowers axillary in pairs, sessile; leaves inversely egg-shaped, toothed." Willd. *Root* annual. *Stem* a foot or a foot and a half high, hispid, simple, or but little branched.

branched. *Upper leaves* lanceolate. 3. C. *endivia*, Linn. Sp. Plant. Mart. Lam. Willd. (C. latifolium, f. endivia vulgaris, Bauh. Pin. 125. Intybum fativum, Dod. Pempt. 634.) Broad-leaved fuccory or common endive. "Peduncles axillary, in pairs; one elongated, one-flowered; the other very fhort, with about four flowers; flowers in heads; leaves oblong, fomewhat toothed; branches zig-zag." Willd. *Root* annual, or at moft biennial, fibrous, milky. *Stem* two feet high, fimple, hollow-channelled. *Leaves* alternate. There is a variety with curled leaves, which is almoft exclufively cultivated in the fouth of England as an early fallad, but no kind of endive is much cultivated in the north. The French make a great confumption of it at their tables, eating it raw in fallads, boiled in ragouts, fried with roaft meat, and as a pickle, and efteeming it a wholefome efculent, which never difagrees with the ftomach. It poffeffes the fame medicinal properties as cichorium intybus, from which Du Tour fuppofes it originally derived; but is a native of the Eaft Indies, according to Willdenow, who affures us that he has in his herbarium a wild fpecimen gathered near Coringo. 4. C. *divaricatum*, Willd. Schoufboe Maroc. p. 197. "Peduncles axillary, in pairs; one elongated; one flowered; the other very fhort, with about two flowers; ftem dichotomous; radical leaves runcinate; ftem ones oblong, toothed." Willd. *Root* annual. *Branches* not zigzag. 5. C. *fpinofum*, Linn. Sp. Pl. Mart. Willd. Lam. Bauh. Pin. 126. Prod. tab. 62. (Chondrillæ genus elegans cæruleo flore, Cluf. Hift. 2. p. 145.) "Flowers axillary, folitary; ftem dichotomous; branches naked, fpinefcent; leaves lanceolate, runcinate-toothed." Willd. *Root* biennial. *Stem* from five to eight inches high, ftiff, fmooth, green, much branched, panicled; ends of the fmaller branches terminating in fharp, ftar-like fpines. *Root-leaves* long, narrow, very fmooth, blunt at the fummit. *Stem-leaves* few, fmall, entire. *Flowers*, like thofe of all the other fpecies, blue, chiefly fituated in the forks of the ftem and branches, but fometimes terminal; florets few. A native of the iflands of the Archipelago and of Sicily, in dry fandy places near the fea-coaft.

C. *pratenfe luteum hirfute afperum*, Bauh. Pin. 126. See Picris *hieracoides*.

C. *pratenfe luteum lævius*, Bauh. Pin. 126. See Crepis *tectorum*

C. *verrucatum*, *zazintha*, Cluf. Hift. 2. p. 144. See Lapsana *zazintha*, Linn.; Zazintha *verrucofa*, Willd.

Cichorium, in *Gardening*, comprehends a plant of the efculent kind, the broad-leaved endive or fuccory (C. *endivia*). It is an annual or biennial plant, the ftem of which rifes two feet in height, upright, round, thick, and branched; the root-leaves many, large, fub-uniform, finuate-toothed, fmooth on both fides; the uppermoft lanceolate, fmall, of a whitifh green colour, thick, and crifp, like cofs-lettuce, having pale, blue flowers, folitary, and peduncled. This is more proper for culinary ufes than for fallads, and lefs hardy than the curled fort. It is moftly cultivated only for ufe in the autumn. It is a native of Japan and China.

The variety chiefly cultivated is the green, curled-leaved, which forms a circular clufter clofe to the ground, twelve or fifteen inches in diameter; the centre-leaves being numerous, very clofely placed, and growing to a large, compact, finely branched, white heart. It is a fine, hardy variety, moftly cultivated for fallads and other culinary purpofes. In its cultivation, the great point is to have the true fort; as fome have long, irregular, thinly-placed leaves, very little curled, and the heart open and loofe. In faving feed, the fulleft leaved, moft curly, regular, bufhy plants, that bottom well, and have the heart perfectly full, clofe, and white, fhould of courfe be chofen: the white, curled, which is fmaller, having white, very fringy, curled leaves, in a circular clufter clofe to the ground, ten or twelve inches in diameter, very full and clofe in the heart, is likewife valuable.

Method of Culture. All thefe plants are raifed from feed, which fhould be fown at different times, from the beginning of June to the end of the following month, upon beds of fine, rich mould. And in order to have very early plants, it is a good practice to make a fowing about the middle of May. But when the fowings are made too early, the plants are apt to run to feed; and when they are deferred too long, they do not attain a fufficient growth before they are fet out in the autumn.

All thefe feparate fowings fhould be performed in as open an expofure as poffible, the ground being prepared by digging it over into proper beds, and reducing the earth well at the time. The feed fhould then be fown thinly over the furface, and lightly raked in. In the light forts of foil, it is the practice of fome to tread it in, but this is feldom neceffary.

Occafional flight waterings fhould be given when the weather is dry, and the plants be kept perfectly clear from weeds, and properly thinned out, fo as not to draw up too faft, and of courfe in a weak ftate. When they are of fufficient growth, as from four or five to fix inches in height, they fhould be planted out where they are to remain, which, for the more early plantings, fhould be in as open a fituation as poffible; but, for the latter crops, the more fouthern, fheltered afpects fhould be preferred, in order that they may ftand the feverity of the winter better. For this purpofe, the ground fhould be rich and mellow, being formed into beds about four feet in width, by digging over to a good fpade's depth: a line fhould then be extended the whole length, and the plants, after being taken up with their roots as perfect as poffible, and their tops and roots trimmed when neceffary, be fet out in regular rows, ten or twelve inches diftance each way, by means of a dibble, a good watering being given immediately afterwards when the feafon is dry. In this mode each bed will contain four rows of plants. But they may be planted without having the ground formed into beds: the raifed-bed method is however preferable, efpecially for the winter crops, and where the foil is inclined to moifture, as keeping the plants more free from ftagnant wetnefs, and preventing their rotting in the winter. In thefe cafes they are often planted at fmaller diftances, as fix or eight inches. Some likewife, for the late crops, are in the practice of forming a fort of banks floping towards the fouth, having the breadths of four or five feet, in which the plants are fet out in rows in the fame manner as above. In this way the plants ftand higher, more dry, and are capable of being protected by frames or mats with greater facility, when the feverity of the winter renders it neceffary. They are likewife more open to the influence of the fun when the weather is fine. Where they have been fet out clofe, in thefe cafes, fome may be drawn out in fuch a manner as to leave the reft ftanding at the proper diftances, which may be planted again in a warm border about February, or the beginning of the following month. Where plants of this fort are fet out in dry weather, it is a good method to make hollow drills, in order that the moifture may be more perfectly retained. It is neceffary that crops fhould be planted out in fome of thefe methods every fortnight or three weeks, from about the middle of June till the beginning of October, or later; by which means they will come forward in perfection, from the later fummer months till the fpring following, in order as they may be wanted for ufe. The only culture that is afterwards neceffary, is merely that of keep-

ing

ing the plants free from weeds, by proper hoeing: and when they have attained their full growth, tying them up, in order that they may be effectually blanched, and rendered ſweet, criſp, and tender for uſe.

Method of Blanching the Plants. This is a proceſs that depends almoſt wholly upon the hearts of the plants being kept perfectly ſecluded from the action of light, and which has been attempted in many different methods, as by tying up the leaves of the plants cloſe together with pieces of baſs; by earthing the plants well up; by placing plane-tiles or boards flat upon them; and by tranſplanting the full-ſized plants into the ſides of raiſed ridges, putting them in the earth nearly up to their tops. The two firſt modes are chiefly employed in the autumn and ſpring crops, and the laſt in the winter. But the two firſt are by much the moſt effectual methods, when performed in a perfect manner, as, while they render the plants quite white and criſp in a regular manner, they do not cramp or reſtrain their growth; the latter of theſe is chiefly to be employed in dry ſoils, and ſhould be done at two or three different times, in order that too many may not be ready at once.

In the third mode, the hearts are rendered ſufficiently white and tender, but the growth of the plants is too much reſtricted, and the buſineſs is not performed in ſo regular or effectual a manner. The plants are likewiſe more liable to rot and be injured by different ſorts of inſects. The laſt is uſeful when there is danger of the plants rotting by an exceſs of moiſture. In whichever way the ætiolation of theſe vegetables is performed, it ſhould conſtantly be done when the plants are quite dry, in the middle of a fine day, as, when executed while they are wet, much loſs and injury are ſuſtained by their rotting. They moſtly become well blanched in the courſe of a fortnight or ſooner, where the light has been excluded in a very perfect manner.

In very ſevere winters, it is of great utility to cover the plants with ſome light material, ſo as to prevent their rotting and being deſtroyed.

Theſe plants may be well preſerved in the winter ſeaſon alſo, by being placed in dry ſand in a ſhed, cellar, or other convenient place which is dry.

In the ſaving of the ſeed of theſe plants, great care ſhould be taken to collect it from the beſt and moſt perfect of the different varieties, and to have it perfectly ripened, as without care in this reſpect it never anſwers well as ſeed in raiſing the different crops.

CICHYRA, or Cichyrus, in *Ancient Geography*, a town of Epirus, according to Pauſanias; ſituated near Cocyta of the Acheron and the marſh Acheruſia.

CICIMENI, a name which, according to Pliny, was given to an ancient people who inhabited the banks of the Tanais.

CICINDELA, in *Entomology*, a beautiful genus of the *Coleoptera* tribe, found in general in dry ſandy places, and in none more abundantly or in greater variety than on the arid tracts of land upon the ſea-ſhore. They are extremely voracious, and prey on every other kind of inſects they can overcome, and on other animal ſubſtances. The larvæ of the cicindelæ are furniſhed with ſix feet; they are commonly whitiſh, ſoft, and long, and have the head ſcaly. Theſe larvæ live chiefly under ground, and, when waiting for prey lurk in a round perpendicular hole, with the head juſt emerging to the ſurface to ſeize upon other inſects that may happen to fall into the cell, or approach near it.

Species.

Longicollis. Thorax elongated, cylindrical, blue; thighs ferruginous. Olivier.

Deſcribed and figured as a Siameſe inſect from a ſpecimen in the Bankſian Cabinet.

Aptera. Thorax elongated, cylindrical; body black; thighs ferruginous. Fabr. *Cicindela aptera*, Lund. Act. Soc. Hiſt. Nat. Havn. i. t. 5. An Eaſt Indian ſpecies.

Angustatus. Thorax cylindrical, blue; wing-caſes teſtaceous, with the tip black. Paykull. Inhabits Germany.

5-Pustulatus. Thorax cylindrical, black; wing-caſes with two ſpots at the baſe, and band in the middle ferruginous. Fabr. Inhabits Paris. Muſ. Tigny.

Grossa. Black; wing-caſes pointed, with three white ſpots. Olivier.

Deſcribed from the Bankſian Cabinet. Inhabits the coaſt of Coromandel.

Cyanea. Blue, gloſſy; mouth teſtaceous. Fabr. Inhabits India.

Megacephala. Black, braſſy; wing-caſes ſtriated with dots; mouth, antennæ, and legs teſtaceous. Olivier. A native of Senegal.

Bicolor. Green, gloſſy; wing-caſes duſky blue, and without ſpots; margin of the abdomen teſtaceous. Fabr. An Indian ſpecies. Bankſian Cabinet.

Campestris. Green; wing-caſes with five white dots. Linn. Geoff. Donov. Brit. Inſ.

A general inhabitant of Europe. Found in ſandy places, and is a beautiful and common inſect.

Germanica. Green; wing-caſes with a dot and lunule near the tip white. Linn.

Inhabits Europe. Found in England, but not common. Donov. Brit. Inſ.

Sylvatica. Purpliſh, fuſcous; wing-caſes with an undulated band, and three dots of whitiſh. Marſh. Ent. Brit. *Cicindela ſylvatica.* Linn.

An European ſpecies; a native of England, but very rare; it has been found on Martleſham Heath near Woodbridge, in Suffolk. Vide Donov. Brit. Inſ.

Hybrida. Somewhat purpliſh; band and two lunules on the wing-caſes white; body ſhining gold. Linn. Found in Europe.

Arenaria. Head and thorax duſky coppery; wing-caſes with black, two lunules and a band in the middle white; body black. Fabr. A native of Barbary.

Littoralis. Duſky, braſſy; wing-caſes blackiſh, with ſix whitiſh dots, that at the baſe lunated, the middle one tranſverſe. Fabr. Inhabits the ſhores of Barbary.

Tristis. Black; wing-caſes with a yellow ſpot in the middle. Olivier. Native place unknown.

Interrupta. Wing-caſes brown, with a yellow dot at the baſe, three interrupted yellow bands, and a ſmall line at the tip. Fabr. Inhabits Africa.

Lunulata. Black; wing-caſes with two lunules, and two white ſpots, the inner one tranſverſe. Forſter. Native country unknown. Bankſian Cabinet.

Lurida. Duſky; wing-caſes with two dots, and three lunules of white, the middle one flexuous. Forſter. Country unknown.

Chinensis. Blue and gloſſy; wing-caſes greeniſh, with two black ſpots, the poſterior one with two white ſpots. Degeer, &c. A native of China.

Flexuosa. Duſky; wing-caſes with four dots and three lunules of white, the middle one flexuous. Fabr. Found on the Spaniſh coaſt. Dahl.

Capensis. Somewhat braſſy; wing-caſes white, with a tri-ramoſe line. Linn. Inhabits the Cape of Good Hope.

Turerculata. Thorax fuſcous, with two tubercles; wing-

wing-cases fuscous and green, varied; margin white, and three-toothed. Fabr. Inhabits New Zealand.

UNIPUNCTATA. Pale purple; tip and dot on the wing-cases white. Fabr. An American species.

BIPUNCTATA. Black; wing-cases with a white dot; legs yellow; thighs black. Olivier. Country unknown. Banksian Cabinet.

SEX-PUNCTATA. Brassy-green; wing-cases with the disk more dusky, and three white dots. Olivier.

QUADRILINEATA. Brassy-green; wing-cases dusky; margin and line in the middle white. Olivier.

CINCTA. Black; wing-cases with a lateral stripe, and three dots of white. Olivier. Inhabits Africa. Hunterian Cabinet.

BIRAMOSA. Dusky, brassy; wing-cases margined with a double branching white line. Herbst. *Cicindela tridentata*, Thunberg. Inhabits India.

SEX-GUTTATA. Green, shining; wing-cases with three marginal white dots. Olivier. Inhabits Virginia.

CATENA. Brassy-green; wing-cases whitish, with six green concatenate dots. Fabr. Thunb. &c. Inhabits India.

MARGINATA. Green; wing cases with a white margin, waved band, and two dots of white. Fabr. Inhabits Virginia.

8 GUTTATA. Dusky; wing-cases with four dots on the disk, and two marginal lunules of white. Olivier. Inhabits America.

TRIFASCIATA. Dusky; wing-cases with three white streaks, the second flexuous. Fabr. An American species. A small variety is said to inhabit Italy.

CAROLINA. Green, shining; tip of the wing-cases, mouth, antennæ, and legs yellow. Linn. A native of North America.

VIRGINICA. Shining; mouth, antennæ, and legs testaceous. Linn. Inhabits Carolina.

CAJENNENSIS. Above fuscous, beneath blue; tail and shanks of the posterior legs testaceous. Fabr. Inhabits Cayenne. Rohr.

EMARGINATA. Blue; mouth, antennæ, and legs rufous; wing-cases emarginate at the tip. Fabr. *Carabus dentatus*, Rossi.

ÆQUINOCTIALIS. Yellow; wing-cases with two broad black bands. Linn. Found in Surinam.

MAURA. Black; wing-cases with six white dots, the third and fourth parallel. Linn. Inhabits the East Indies.

MINUTA. Brassy; wing-cases with four marginal yellow lunules. Fabr. Inhabits India.

JAPONICA. Violet; wing-cases with the base, tip, and band coppery; and a yellow band and two dots. Thunberg. Inhabits Japan.

AUSTRIACA. Green; breast, and base of the abdomen beneath red bronzed; wing-cases with a very thin golden margin and a few white dots. Schrank. Inhabits Austria.

RIPARIA. Brassy-green; wing-cases with broad excavated spots. Linn.

Inhabits Europe, and is found, though generally sparingly, in England. Donov. Brit. Inf.

ULIGINOSA. Brassy-green; wing-cases striated with blue impressed dots. Panoz. &c. Inhabits Europe.

AQUATICA. Brassy, glossy; head striated. Linn. Inhabits Europe.

STRIATA. Brassy; wing-cases striated; legs yellowish. Paykull, &c.

Discovered on the sandy coast of Glamorganshire by Mr. Donovan. Vide "Descriptive Excursions, South Wales, &c."

SEMIPUNCTATA. Brassy and glossy; wing-cases dotted; back very glabrous. Gmel. *Cicindela striata*, Degeer. Found in Europe.

FLAVIPES. Dusky-brassy; wing-cases somewhat clouded; legs pale yellow. Linn. An European species.

BIGUTTATA. Brassy; wing-cases polished, and yellowish at the tip. Gmel. &c. Inhabits England, and other parts of Europe.

CICINES, in *Ancient Geography*, a people of Greece, in Attica. Hesychius places them in the Acamantide tribe.

CICISBEO, an Italian term, in its etymology signifying a *whisperer*; which has been bestowed in Italy both on lovers, and on those who to outward appearance act as such, attending on married ladies with as much attention and respect as if they were their lovers. When the custom of secluding the wife from all mankind but her husband took place in Italy, it became the fashion that she should never be seen with her husband, and yet always have a man at her elbow. The Italian husbands, finding that confinement was a plan generally reprobated, and that any appearance of jealousy subjected the husband to ridicule, agreed that their wives should go into company or attend public places, but always with a friend whom they could trust, and who, at the same time, should not be disagreeable to the wife. As this compromise could not fail of being acceptable to the women, the system soon became universal all over Italy, for the woman to appear at public places leaning upon the arm of a man; who, from their frequently whispering together, was called her Cicisbeo. It was stipulated, at the same time, that the lady, whilst abroad under his care, should converse with no other man but in his presence, and with his approbation; he was to be her guardian, her friend, and gentleman-usher. The present custom is, that this obsequious gentleman visits the lady every forenoon at her toilet, where the plan for passing the evening is settled; he disappears before dinner, for it is usual in Italy for the husband and wife to dine together tête-à-tête, except on great occasions, as when there is a public feast. After dinner the husband retires, and the Cicisbeo returns and conducts the lady to the public walks, the converfazioné, or the opera; he hands her about wherever she goes, presents her coffee, sorts her cards, and attends with the most pointed assiduity till the amusements of the evening are concluded; he accompanies her home, and delivers up his charge to the husband, who is then supposed to resume his functions. At the beginning of this institution, the husbands, says Dr. Moore (View of Society and Manners in Italy, vol. 2.) preferred the Platonic swains, who professed only the metaphysics of love, and whose lectures they imagined might refine the ideas of their wives, and bring them to the same way of thinking. In many instances, no doubt it would happen, that the Platonic admirer acted with "less seraphic ends;" but these instances seem only as proofs that the husbands were mistaken in their men; for however absurd it may appear in the eyes of some people, to imagine that the husbands believe it is only a Platonic connection which subsists between their wives and the Cicisbeos; it is still more absurd to believe, as some strangers who have passed through this country seem to have done, that this whole system of Cicisbeism was from the beginning, and is now, an universal system of adultery, connived at by every Italian husband. To get rid of this difficulty, it is supposed that the men, who, of all the inhabitants of Europe, were the most scrupulous with regard to the chastity of their wives, should acquiesce in, and in a manner become subservient to, their prostitution.

tion. In ſupport of this ſtrange doctrine, it is aſſerted, that the huſbands being the Cicisbeos of other women, cannot enjoy this privilege on any other terms; and are therefore contented to ſacrifice their wives for the ſake of their miſtreſſes, Dr. Moore has no doubt, that ſome individuals may be profligate enough to act in this manner; but that ſuch a ſyſtem is general, or any thing near it, in Italy, ſeems to him perfectly incredible, and contrary to the beſt information received by him, whilſt he remained in the country. It is alſo urged, that moſt of the married men of quality in Italy act in the character of Cicisbeo to ſome woman or other; and thoſe who are not Platonic lovers, ought to ſuſpect that the ſame liberties are taken with their wives which they take with thoſe of their neighbours. However men have a wonderful faculty of deceiving themſelves on ſuch occaſions. So great is the infatuation of their vanity, that the ſame degree of complaiſance, which they conſider as the effect of a very natural and excuſable weakneſs, when indulged by any woman for themſelves, they would regard as a horrible enormity if admitted by their wives for another man; ſo that whatever degree of licentiouſneſs may exiſt in conſequence of this ſyſtem, the majority of huſbands (as Dr. Moore is convinced) make exceptions in their own favour, and their ladies find means to ſatisfy each individual that he is not involved in a calamity, which, after all, is more general in other countries, as well as in Italy, than it ought to be. The Cicisbeo is, in many inſtances, a poor relation or humble friend, who, not being in circumſtances to ſupport an equipage, is happy to be admitted into all ſocieties and to be carried about to public diverſions, as an appendage to the lady. There are alſo Cicisbeos of a very different ſtamp, whoſe figure and manners might be ſuppoſed more agreeable to the ladies they ſerve, than to their lords. But, ſometimes, the huſband is poor, and the Cicisbeo rich. This ſyſtem is unknown to the middle and lower ranks; inſomuch that a perſon who attempts to viſit the wife or miſtreſs of any of the trades-people without their permiſſion is in no ſmall danger of a coltellata. This Italian cuſtom has been ſpoken of very reproachfully by ſome writers: Mr. Baretti (Account of the Manners, &c. of Italy, vol. i. c. 8.) has taken great pains to vindicate it. He aſcribes it to a ſpirit of gallantry, derived from the ages of chivalry, and much heightened and refined by the revival of the Platonic philoſophy in Italy, about the thirteenth century; and by the verſes of Petrarch in compliment to the beautiful Laura, and his numerous imitators.

In France, under the old ſyſtem, there was an important claſs of females, who might not improperly be denominated female Cicisbeos. When the rank of a woman of faſhion had enabled her to preſerve a degree of reputation and influence in ſpite of the gallantries of her youth and the decline of her charms, ſhe adopted this kind of equivocal character, and, relinquiſhing the adoration claimed by beauty, and the reſpect due to age, charitably devoted herſelf to the inſtruction and advancement of ſome young man of perſonal qualifications and uncertain fortune. By her exertions he was promoted in the army, or diſtinguiſhed at the levee, and a career, begun under ſuch auſpices, often terminated in a brilliant eſtabliſhment.

CICLA, in *Botany*. See Beta *cicla*.

CICLUT, in *Geography*, a fortreſs of Dalmatia, ſeated on an iſland formed by the river Narenta, taken from the Turks by the Venetians in 1694; 5 miles S.W. of Narenta, and 40 N. of Raguſa.

CICOLES, in *Ancient Geography*, a port of Thrace, which, according to Suidas, was that of Terone.

CICOLI, in *Geography*, a town of Naples, in the province of Abruzzo Ultra; 13 miles S.W. of Celano.

CICONES, in *Ancient Geography*, a people of Aſia placed by Pliny between the Indus and the Attæciani.—Alſo, a people of Thrace, who inhabited the country lying between the Hebrus and the Melas. The city of Enos, famous on account of the tomb of Polydorus, was their capital. Homer (Iliad. β) ſpeaks of three of their kings. In his Odyſſey, he ſpeaks of them as a numerous, well-diſciplined, and warlike people. From Herodotus we learn, that they had formerly inhabited part of the Samothracian towns, ſince the promontory of Serrhium had belonged to them; and that, in proceſs of time, they were driven more to the north and to the weſt by the Samothracians.

CICONIA, in *Ornithology*, the Ardea *Ciconia* of Linnæus and Gmelin, or *Ardea alba*, with black orbits and wing-quills, and ſanguineous bill, legs, and ſkin. This is the *white ſtork* of Pennant and Latham, and the *la cicogne blanche* of Buffon. It inhabits Europe, Aſia, and Africa, but is more rarely met with in Italy and England; ſettling in towers, chimnies, and ruins near our dwellings, fiſhing in our rivers, purſuing its prey in our gardens, and occaſionally taking up its abode in the midſt of cities. For a further account of it, ſee Stork.

Ciconia *nigra*, *ardea fuſca*, having its breaſt and belly white, the *cicogne noire* of Buffon, the black ſtork of Pennant, Ray, Willughby, and Latham. It is found in the Swiſs Alps, Poland, Pruſſia, Lithuania, Sileſia, and many other parts of Germany, and as far as the Caſpian ſea. This ſpecies is ſavage and ſolitary, ſhunning the habitations of men, and haunting the deſert fens. Theſe birds ſoar to a great height. Numerous flocks of them paſs in the ſpring over Sweden, and ſtretch farther towards the north; they return towards the ſouth in autumn. See Stork.

Ciconia *americana* of Briſſon, Ray, and Willughby, the *maguari* of Buffon, the *ardea maguari* of Gmelin, and *American ſtork* of Latham. It inhabits the hotter parts of America, particularly Braſil, and was firſt deſcribed by Marcgrave. Its orbits and legs are red, its bill cinereous, the quills and great coverts of the wings black, gloſſed with green; and the whole body, head, neck, and tail inveſted with white feathers, which below the neck are of a conſiderable length and pendulous.

Ciconiæ, one of the five ſections of the *ardea* genus, according to Gmelin, including the three preceding ſpecies. See Ardea.

CICONIUM Promontorium, in *Ancient Geography*, a promontory of Aſia Minor, upon the Boſphorus of Thrace.

CICONUM Flumen, a river of Thrace, paſſing through the country of the Cicones, and mentioned both by Pliny and Ovid.

Ciconum *Mons*, a mountain of Thrace, ſuppoſed to be the ſame with Iſmanus.

CICOYRUS, a town of Epirus, in Theſprotia, ſituated, according to Strabo, on the "Dulcis portus," who ſays that it was once called Ephyra.

CICSITANUS, an epiſcopal town of Africa, in the proconſular province.

CICUS, a river of Thrace, which diſcharged itſelf in the port of Byzantium.

CICUTA, in *Botany*, (in Latin authors, denotes the internode or ſpace between the joints of a reed, or of any plant uſed by ſhepherds for making their rural pipes; and as the hollow ſtems of ſeveral plants belonging to the natural family of umbelliferæ, known in England by the popular name of kecks or keckſies, were frequently employed for that purpoſe, the name was particularly applied to them, eſpecially to thoſe which are of a poiſonous nature,

ture, one of them having been employed by the Athenians as a mode of capital puniſhment.) Linn. Gen. 354. Mart. ſub. voce. Willd. 550. Cicutaria; Riv. Lam. Juſſ. Vent.) Claſs and Order, *pentandria digynia*. Nat. Ord. *Umbellatæ*, Linn. *Umbelliferæ*, Juſſ.

Gen. Ch. *Umbel univerſal* roundiſh; rays many, equal; involucre none, or conſiſting of one or two linear leaves. *Umbel partial* roundiſh; rays many, equal, ſetaceous; involucre, many-leaved; leaves briſtly, ſetaceous, ſhort. *Calyx* of the florets ſcarcely viſible. *Cor.* Florets all fertile conſiſting of five, egg-ſhaped, inflected, nearly equal petals. *Stam.* Filaments five, capillary, longer than the corolla. *Piſt.* Germ inferior; ſtyles two, filiform, longer than the corolla, permanent; ſtigmas headed. *Peric.* none; fruit ſomewhat egg-ſhaped, furrowed, diviſible into two. *Seeds* two, convex and ſtriated on one ſide, flat on the other.

Eſſ. Ch. Fruit ſomewhat egg-ſhaped, furrowed.

Sp. 1. C. *viroſa*. Linn. Sp. Pl. Mart. Willd. Flor. Dan. tab. 208. Eng. Bot. 479. Woodv. Sup. tab. 248. (Cicutaria aquatica; Lam. Sium; Bauh. Pin. 154, n. 3. Hal. Helv. n. 781. Mor. Hiſt. 3, tab. 5. fig. 4. Umb. tab. 5. S. paluſtre alterum, foliis ſerratis; Tourn. 308. Lob. Ic. 208.) Long-leaved water hemlock. "Umbels oppoſite the leaves; petioles margined, obtuſe." *Root* perennial, tuberous, hollow, cellular; fibres ſomewhat whorled. *Stem* three or four feet high, branched, furrowed, leafy; branches rather erect. *Leaves* twice ternate; larger ones pinnate; leaflets lanceolate, acute, ſerrated, ſmooth; ſtipulæ linear, adnate to the petioles, and a little ſhorter. *Umbels* erect, many-rayed; partial ones denſe. *Flowers* white, regular, ſmall; calyx five-parted; petals rolled inwards. *Fruit* compreſſed, rounded, almoſt didymous, ribbed. A native of ſtagnant pools and the margins of rivers in England and all the north of Europe, but not common in England. Towards the end of autumn, the root for the ſucceeding ſummer is formed out of the lower part of the ſtem; and being tranſverſely divided into many large unequal cells, ſo as to become ſpecifically lighter than water, it is buoyed up when the rivers or pools ſwell in winter. The old root then rots, floats all the winter, and in rivers is frequently carried to conſiderable diſtances. In the ſpring the old root is waſhed away, and the new one, on coming near the ſoil, ſends out many ſlender fibres, by which it is again fixed, grows, and flowers. It is reckoned one of the moſt virulent of our vegetable poiſons to the human race, and is equally fatal to cows and ſwine; but horſes, hogs, and goats eat it with impunity. The beſt remedy againſt its deleterious effects, when unfortunately taken into the ſtomach, is a ſpeedy emetic, ſucceeded by vegetable acids or oils. 2. C. *bulbifera*, Linn. Sp. Pl. Mart. Willd. (Cicutaria bulbifera; Lam. Enc. Ammi foliorum laciniis capillaribus caule angulato; Gron. Virg. 31. Umbellifera aquatica, foliis in monatiſſima et plane capillaria ſegmenta diviſis. Rai. Sup. 260.) "Stem bulbiferous," Linn. "Leaves divided into very numerous linear ſegments; branches bulbiferous." Lam. *Stem* a foot and a half high, ſmooth, branched; branches not bearing umbels, very ſlender, zig-zag, furniſhed with ſimple narrow leaves, and frequently with other ſmall axillary branches; from the axils of each branch ſprings an oval bulb, ſcarcely the ſize of a grain of wheat. *Flowers* white, ſmall, forming a ſmall umbel at the ſummit of the ſtem; univerſal umbel of one or two leaves. A native of Virginia and Canada. 3. C. *maculata*. Linn. Sp. Pl. Mart. Willd. (Cicutaria maculata. Lam. Enc. ægopodium foliolis lanceolatis, acuminatis, ſerratis; Gron. Virg. 32. Angelica caribæarum; Pluk. Alm. tab. 76. fig. 1. A. virginiana, foliis acutioribus, ſemine ſtriato; Moriſ. Hiſt. 3. p. 281. Myrrha; Mitch. Gen. 18.) "Serratures of the leaves mucronate, petioles membranous, two-lobed at the tip." Linn. "Leaves twice-pinnated; leaflets ſerrated; partial involucres ſhorter than their umbels." Lam. *Root* perennial, creeping. *Stem* a foot and a half or two feet high, upright, ſmooth, hollow, purple-brown, ſpotted near the bottom, a little branched towards the top. *Leaves* twice pinnated; leaflets lanceolate, green, finely ſerrated. *Flowers* white, ſmall, almoſt regular, generally without an univerſal involucre. A native of watery places in Virginia.

Cicuta, in the *Materia Medica*. *Conium Maculatum*, Linn. Hemlock.

The poiſonous qualities of this plant have been known for a great length of time; but it was ſcarcely adopted in medicine before the experiments of Dr. Stork, in 1760, ſince which time it has been introduced in moſt of the pharmacopœias of Europe. Although it has by no means anſwered the ſanguine expectations which were entertained of its virtues in ſeveral of the moſt formidable, and hitherto incurable diſeaſes, it is ſtill found to poſſeſs ſeveral valuable medicinal qualities.

The whole of the plant appears to poſſeſs the ſame power of affecting the human body, ſo that this power reſides in the common juice which pervades the plant. The part actually employed in medicine is all above the root, and as the plant is very ſucculent, it readily yields a conſiderable quantity of juice on ſtrong preſſure, which, when gradually inſpiſſated by evaporation, affords a brown *extract*, or *inſpiſſated juice*, which, with the dried leaves, are the only pharmaceutical preparations in uſe. This plant has a ſtrong and unpleaſant ſmell, but little, if any, peculiar taſte. When taken in a large doſe it produces vertigo, coma, convulſions, and ſometimes death. In ſmaller doſes it occaſions a trembling of the limbs, ſickneſs, head-ach, and ſenſe of fullneſs in the eyes; ſometimes temporary deafneſs, and now and then diarrhœa. Its effects, therefore, properly require it to be claſſed among the *narcotic* medicines, and it often ſhows only the more valuable properties of narcotics, in relieving pain and irritation of the body, and inducing ſleep.

The following are Dr. Withering's directions for preparing the extract, or inſpiſſated juice. "Let ſeveral people be employed to gather the plant, and as faſt as it is cut let others carry it in hand-baſkets to the preſs. Let the juice be immediately ſqueezed out, and as faſt as it runs out of the preſs it muſt be put over the fire and boiled, till three parts out of four of the whole liquor is waſted. Then it muſt be removed to a water-bath, and evaporated to the conſiſtence of honey. If it is now taken and ſpread thin upon a board or marble ſlab, and expoſed to the ſun and air, it will ſoon be of a proper conſiſtence to make pills."

In this ſimple method is the extract of cicuta prepared. This extract is of a dark greeniſh brown, almoſt black, of a ſtrong diſagreeable ſmell, and a ſlightly pungent taſte, but without bitterneſs. Like the other extracts of herbaceous plants (for the chemical properties of which ſee the article Extract) it contains but little reſin, but is conſiderably deliqueſcent, owing to the preſence of ſome acetite of potaſh, as may be at once perceived by adding a few drops of ſulphuric acid, which will diſengage a pungent vapour of acetous acid. Owing to this deliqueſcence the extract ſhould be kept in pots covered with bladders, for in the open air it ſoon moulds, and its virtues are loſt.

Some pharmaceutical authors direct that the expreſſed juice ſhould ſtand a ſhort time to clarify, and only the clearer part evaporated; but this is decidedly injurious, as there

there is every reafon to believe that the part, which would in this cafe be rejected as feculence, is at leaft as efficacious as the clear juice, fo that, as Dr. Withering has directed, the entire juice fhould be employed. More care is required to avoid empyreuma in the preparing of this extract, than in that of gentian, cinchona, and other plants, where the bitter principle is chiefly required, for the virtue of the hemlock is foon injured by heat. But as infpiffation in the water-bath is exceffively tedious, many chemifts ufe ovens very moderately heated, or ftoved chambers, which in the large way are preferable, as they afford a greater furface for evaporation. Inftead of compleating the evaporation to the proper pillular confiftence, fome direct that the foft extract fhould be made into a pillular mafs, by adding about a fifth of its weight of the leaves of the plant dried and powdered.

With all the care that can be taken in keeping this extract, its virtues are materially impaired in a few months, fo that thofe who are in the habit of employing it fhould always provide a frefh ftock every year. The feafon for gathering this, as of moft other herbaceous plants ufed in medicine, is when the plant is full grown, and about to flower. From the teftimony of Dr. Withering, the dried leaves are more uniform in their operation, and lefs liable to fpoil by keeping, than the extract. They fhould be kept in clofely-ftopped bottles, and in the dark. In exhibiting the hemlock, the extract is ufually made into pills of about two grains each, of which one may be taken for a dofe three times a day, and this may be rapidly increafed, till fome of the peculiar effects of the hemlock be perceived, after which the fame dofe, or nearly fo, may be perfifted in for as long a time as is thought proper. Of the powder, from fifteen to twenty grains may be taken twice or thrice a day. Of all the powerful narcotics the cicuta is perhaps the moft uncertain in its operation in a given dofe. This, no doubt, in part depends on the want of uniformity in the ftrength of the feveral preparations; but even with the fame individual preparation, fome perfons will be fenfibly affected by a few grains, and others will bear perhaps eight or ten times the quantity. In its moft favourable operation it fimply alleviates pain, without occafioning ficknefs, or head-ach, and often, without producing a greater tendency to fleep than what belongs to the mere effect of the fufpenfion of pain in haraffing and chronic difeafes; fo that it is then a moft valuable fubftitute to opium, the good effect of which it fecures, without occafioning the inconveniences infeparable from this valuable medicine. Unfortunately, however, it is (comparatively fpeaking) but rarely that the cicuta operates in this favourable manner, and very frequently it either produces no effect at all, except naufea, or fuch a degree of head-ach, vertigo, and debility, which render it unfafe to continue its ufe.

The cicuta was chiefly recommended by Dr. Stork, as a new and valuable remedy for cancer, and fchirrous tumours of all kinds, for chronic ulcerations depending on fcrofula, or any conftitutional difeafe. The obfervations of others, however, have led to a jufter eftimation of its powers, for (in this country at leaft) no dependence can be placed on it as a cure for cancer, though it is often ufeful as a palliative. It has been employed alfo with fome fuccefs in the hooping cough, and other fpafmodic diforders. As an external application, it is of great ufe in painful and extenfive fores of a cancerous nature, when applied as a warm fomentation or poultice, giving confiderable eafe, and changing the nature of the difcharge, from a thin fœtid fanies to healthy pus. In this, part of the good effect is doubtlefs to be afcribed to the narcotic quality of the plant, but part alfo to the mode of application, and to the efficacy which appears common to almoft all frefh vegetables; fince a fimilar advantage is derived from the carrot poultice, from the marfh-mallow fomentation, and from many other of the medicinal herbs in common ufe.

The cicuta of the ancients, is a fecret now fcarce poffible to be difcovered. Wepfer, in an exprefs treatife on the fubject, will have it the Œnanthe *cicutæ facie, fucco virofo;* which he defcribes by the name of *cicuta aquatica;* and of the difmal effects of which he gives a very ample relation. At leaft the violence of this plant makes it a much fitter inftrument of hafty death than the common cicuta or hemlock, which is much lefs malignant. Though fome have fuggefted, that the poifonous draught to which the Athenians doomed their criminals, was an infpiffated juice compounded of the juice of cicuta and fome other corrofive herbs. Vid. Mead's Effay on Poifons, ap. Bibl. Anal. Med. tom iii. p. 281.

Socrates drank the cicuta. Plato, in his Dialogue on the Immortality of the Soul, obferves, that "The executioner advifed Socrates not to talk, for fear of caufing the cicuta to operate too flowly." M. Petit, in his "Obfervationes Mifcellaneæ," remarks, that this advertifement was not given by the executioner out of humanity, but to fave the cicuta: for he was only allowed fo much poifon *per ann.* which if he exceeded, he was to furnifh the reft at his own expence. This conftruction is confirmed by a paffage in Plutarch: the executioner who adminiftered the cicuta to Phocion, not having enough, Phocion gave him money to buy more; obferving, by the way, that it was odd enough, that at Athens a man muft pay for every thing, even his own death.

CID, in *Biography*, a Spanifh hero, whofe real name was Don Rodrigo Diaz de Bivar, was defcended from Diego Laynez, a perfon of confiderable family, and was brought up at the court of the kings of Caftile. On account of his great valour, he was, at an early age, created a knight. Before he received this honour, five Moorifh kings had united their forces and plundered Caftile. On the mountains of Oca, Rodrigo fell upon them as they were removing their fpoil, recovered the whole booty, and took the five kings prifoners, whom he treated with refpect, and difmiffed on a promife of tribute. The fpoil he diftributed among his followers. King Fernando, having received tidings of this victory, turned his arms againft the Moors of Portugal, and befieged Coimbra, which he took. Here Rodrigo was knighted. When meffengers arrived at Zamora with tribute to Rodrigo from the five kings, he offered a fifth of it to his fovereign as his due. Fernando would not accept it; and hearing the Moors addrefs Rodrigo by the title Cid or lord (Cid being the Arabic term for lord), he ordered him from that time to bear this honourable name. Upon the king's death, he divided his kingdoms among his children; allotting Caftile to Sancho, the eldeft; Leon to Alonfo, and other portions to Garcia, and to his two daughters. This

This partition occaſioned a conteſt among the brothers. When Sancho came to the crown, Rodrigo was his lieutenant general in his war againſt his brother Alonſo. He followed his ſovereign to the ſiege of Zamora, where Sancho was ſlain by treachery, and conducted back in good order the Caſtilian troops, with the dead body of the king. Alonſo was invited to the crown on condition of purging himſelf by oath of all ſuſpicion of concern in his brother's death. None of the nobility, who, as a body, had impoſed the condition, dared venture to exact the oath at the convention; Rodrigo, with a ſpirit of true loyalty to his departed maſter, admininiſtered it, and even obliged the king to repeat it. Before theſe adventures, he had married, with the concurrence of king Fernando, Ximena, daughter to count Gomez, whom he had killed in ſingle combat becauſe he had inſulted his father in his old age; an event, which, affording a fine diſplay of the contending paſſions in the perſon of the heroine, as at once the daughter and lover, has been the ſubject of a Spaniſh play, imitated by Corneille in the tragedy of "The Cid." Rodrigo, finding that Alonſo continued to reſent his conduct in exacting the above-mentioned oath, aſſembled his friends, and thoſe on whoſe fidelity he could rely, at the head of whom he entered Arragon, ravaging and plundering the country. He made himſelf maſter of the caſtle Alcocer, where, being joined by a number of freebooters, attracted by his fame, he made perpetual incurſions into the neighbouring Mooriſh territories. He afterwards ſold Alcocer to the Moors, and diſtributed its price among his followers. At length he penetrated ſouth of Saragoſſa, and fixed his reſidence in a ſtrong fortreſs called to the preſent times, the Rock of the Cid, where he maintained himſelf as an independent ſovereign. In the mean while Alonſo's hatred to the Cid had gradually abated; and when his aſſiſtance was needed, a reconciliation between them took place. Having accompanied Alonſo to the ſiege of Toledo, and accompliſhed that ſervice, he returned to Saragoſſa. Hearing of the murder of Yahia, king of Valencia, he deſired the aſſiſtance of Alonſo to enable him to revenge the deed; the requeſt was granted, and Rodrigo, in 1094, took Valencia, and held it till his death in 1099. Fiction has detailed ſeveral circumſtances that preceded and followed his death, which it is beſides our purpoſe to relate. As the Moors approached the city, he gave orders that the event of his death ſhould be concealed; and having aſſured his followers of victory, he expired. Having collected the whole treaſure of Valencia, and placed upon a war horſe the dead body of the Cid, they formed a proceſſion in order to leave the city. His wife, Ximena, with 600 knights as her guard, formed part of the train. The Moors were attacked and totally routed; and the Chriſtians, ſpoiling their camp as they paſſed through it, proceeded with the body towards Caſtile. Inſtead of burying the body, which was preſerved by the myrrh and balſam, with which it had been embalmed, in an apparently ſound ſtate, they placed it upright upon his ivory ſeat in the church, at the right hand of the altar. Ximena took up her daily abode in the church, and having ſurvived her huſband four years, was buried at his feet. After ten years, the body began to moulder; it was then interred in its garments, and with the ſword, by the ſide of Ximena. The hiſtory of the Cid, who flouriſhed from the year 1064, when he is firſt mentioned, till his death in 1099, under the reigns of Fernando the Great, and his ſons Sancho el Bravo, and Alfonſo VI. in whoſe time he eſtabliſhed himſelf as conqueror in the city of Valencia, is blended with fiction of the moſt beautiful kind. It is furniſhed both by his chronicle, and alſo by the "General Chronicle of Spain," compiled by order of Alfonſo the Wiſe, in the middle of the 13th century, about 150 years after Rodrigo's death. There is a poem upon his life which is probably a century older.

CIDAGER, or Cidaia, in *Geography*, a town of the iſland of Java.

CIDARES Kleinii, in *Natural Hiſtory*, hemiſpheric or ſpheroidal ſections of the Echinus.

CIDARIS, a ſpecies of Echinus; and a ſpecies of Turbo.

Cidaris, in *Ancient Geography*, a river of Thrace, which diſcharged itſelf into the harbour of Byzantium.

Cidaris, in *Scripture Hiſtory*, the mitre uſed by the Jewiſh high prieſts. Whenever there is mention of the high prieſt's mitre, the Hebrew word made uſe of to expreſs it is always *miznepheth*; and *myghaoth* is uſed to ſignify the bonnet belonging to common prieſts. The rabbins ſay the ſame thing is meant by both theſe terms, and that the bonnet uſed by prieſts in general was made of a piece of linen cloth ſixteen yards long, which covered their heads like an helmet or a turban; and they allow no other difference to be between the high prieſt's bonnet, and that of other prieſts, than this, that one is flatter, and more in the form of a turban, whereas the other worn by ordinary prieſts roſe ſomething more in a point. Exod. xxviii. 4.

It is to be obſerved, that the Hebrew prieſts never appeared in the temple without covering their heads. And ſtill at this day it is reckoned an incivility in the Eaſt, and a mark of contempt, for any man to pull off his hat or turban to another, or to ſhew his naked head before any one.

CIDER. See Cyder.

CIDES, in *Ancient Geography*, a town of Aſia Minor, in Ætolia.

CIDIAS, in *Biography*, an ancient Greek painter, contemporary with Eufranor, about the hundred and fourth olympiad. Amongſt other works, he painted a picture of the Argonauts, which was afterwards bought by Hortenſius for the ſum of forty-four thouſand ſeſterces (about fourteen thouſand four hundred florins), and placed it in a ſmall temple, built on purpoſe to receive it, in his villa at Tivoli. It was afterwards removed by M. Agrippa to the Portico of Neptune which he had fabricated in Rome. Dion. Caſſ. lib. 53. Della Valle, Vite dei Pittori Antichi.

CIDNUS, in *Geography*, a river of Cilicia, which ſprung from the Antitaurus, paſſed through Tarſus, and diſemboguedi tſelf into the Mediterranean, near the city of Anchiale. It was famous for the rapidity of its ſtream, and the coldneſs of its waters, which proved very dangerous to Alexander.

CIDYESSUS, a town of Aſia, ſituated in the northern part of Phrygia, between the towns of Midæum and Nacoleia. This town, like others of the proconſular province of Aſia, was governed by a ſenate, the preſidents of which were denominated archontes. The worſhip of Cybele was eſtabliſhed at Cidyeſſus. The inhabitants of this town rendered alſo a particular worſhip to Jupiter. The firſt miniſter of his temple preſided at the celebration of the games which had been eſtabliſhed in this place in honour of that deity. Cidyeſſus was an epiſcopal town in Pacatian Phrygia.

CIECIEREF, in *Geography*, a river which riſes in Poland, and runs into the Dnieper, 28 miles W. of Kiov.

CIEKANOW, a town of Poland, in the palatinate of Maſovia; 40 miles N. of Warſaw.

CIENFUEGIA, in *Botany*, Willd. 1277. Cavan. diſſ. 3. p. 174, tab. 72. fig. 2. Claſs and order, *monadelphia dodecandria*. Eſſ. Ch. Calyx double, outer one twelve-leaved; leaflets briſtle-ſhaped. Corolla five-petalled, ſtyle filiform, ſtigma club-ſhaped. Capſule three-celled, three-ſeeded.

Sp. C. *digitata*. *Root* perennial. *Leaves* alternate, petioled, ſmooth, three or five-cleft; ſegments lanceolate, rather obtuſe, either quite entire or toothed. *Peduncles* one-flowered, axillary. *Outer calyx* ſhort; inner one five-cleft. Nearly allied to Hibiſcus, but diſtinguiſhed from it by its club-ſhaped ſtigma, and three-celled capſule, with one ſeed in each cell.

CIEUX, in *Geography*, a town of France, in the department of Upper Vienne, and diſtrict of Belac, containing about 1200 inhabitants; 13 miles N.W. of Limoges.

CIFUENTES, a town of Spain in New Caſtile; 22 miles S. of Siguença.

CIGALE and CIGALON, in *Natural Hiſtory*, names given by the French to ſpecies of the *Cicada*.

CIGLIANO, in *Geography*, a town of Italy, in the Orvietan; 4 miles N. of Orvieto.

CIGNANI, Carlo, in *Biography*, an hiſtorical painter, of conſiderable eminence, born at Bologna in the year 1628. In infancy he received inſtruction from a maſter of little note, Gio. Batt[a] Cairo; but afterwards became the diſciple of Albano, the amenity of whoſe inventions he was ever deſirous to emulate: his ſtyle, however, both as to drawing and colouring, is principally founded on the model of Correggio, whoſe works he attentively ſtudied, and to which he not unfrequently added ſomething of the grace of Guido: and although he fell far ſhort of his great prototype, he is deſervedly conſidered one of the beſt painters Italy could boaſt, in the degenerate times in which he lived.

He painted many large works in the place of his nativity, as well as in other cities of Italy, and excelled equally in freſco and in oil. Amongſt his moſt admired performances, are four ſmall ovals, containing ſacred ſtories, and each ſupported by two beautiful boy-angels, at St. Michele in Boſco at Bologna; and an altar-piece repreſenting, as it is called, the conception of the virgin, in a monaſtery at Piacenza. The virgin, with a graceful dignity, bruiſes with her foot the head of the ſerpent, and the child, who is between her knees, ſuperadds the preſſure of his own little foot to that of his mother.

The Abbé Lanzi, in his *Storia Pittorica*, ſpeaks with rapture of this picture, which, for thought and execution, he conſiders one of the chef d'œuvres of Cignani. There is likewiſe a large work by this maſter in a room in the garden of the Ducal Palace at Parma, with ſubjects alluſive to the power of love. But his greateſt work is at Forli, where Cignani ſpent the latter part of his life: it is a cupola, which, in imitation of his admired Correggio, he painted in freſco, with the ſubject of the aſſumption of the Madona, amidſt a multitude of the angelic choir. This, in the opinion of ſome of the beſt judges, is the moſt intereſting work of painting of the period in which it was produced: it is ſaid to have employed the artiſt 20 years.

He painted, amongſt other cabinet pictures, many ſmall madonas and holy families in oil on copper, upon which his hiſtorian, Zannotti, beſtows the higheſt encomiums.

The ſtyle of Cignani is ſimple, broad, and of great relief, but ſeldom evinces loftineſs of conception, or more than ordinary force or delicacy of expreſſion. He died in the year 1719, at the advanced age of 91. Zannotti, Accademia Clementina. Lanzi, Storia Pittorica.

CIGNAROLI, Giovanni Bettino, a Veroneſe painter, one of the beſt of his time, was born in the year 1706, and was educated in the ſchool of Santo-Prunati. The works of Cignaroli were ſo admired, that he many times received the moſt preſſing invitations to ſettle in foreign courts, but the love of his country proved ſuperior to every other inducement, and he never could be prevailed on to quit Verona.

The works of Cignaroli are diſperſed in the galleries and churches of the different parts of Italy, as well as the palaces of foreign potentates: they are by no means, however, of equal merit. Amongſt others is a flight into Egypt, in the church of St. Antonia Abate at Parma, upon which Lanzi beſtows the higheſt encomiums.

The Virgin with the child is repreſented paſſing over a little narrow bridge, and old Joſeph is aſſiſting them on the dangerous occaſion, with a care of anxiety for their ſafety, which is admirably expreſſed: ſo entirely is he abſorbed in this one idea, that he pays no attention to part of his own mantle which is floating in the ſtream. The angels, who, in the cuſtomary manner, are introduced, poſſeſs much grace, and the madona has a dignified deportment, ſomewhat reſembling thoſe of Carlo Maratti.

There is frequently a pleaſing expreſſion and novelty of conception in the works of Cignaroli, and his compoſition is good; but his colouring is ſometimes more plauſible than true, and he was rather extravagant in the uſe of reds and greens in his fleſh: we may add, that his effects of chiaroſcuro are not unfrequently too far-fetched, and ſeem to want their foundation in nature.

He left many ſcholars, among whom was a brother named Giandomenico Cignaroli, whoſe pictures in Bergamo are ſaid to poſſeſs merit.—Gio. Bettino Cignaroli died in the year 1770, and the particulars of his life were publiſhed by P. Gregorio Bevilacqua. Lanzi, Storia Pittorica.

Cignaroli, (by ſome called Cingiaroli), Martino and Pietro, two brothers, Veroneſe painters, who, educated in the ſchool of Giulio Carpione, afterwards ſettled in Milan, where they were eſteemed for their landſcapes and bambocciate, and where Martino had a ſon called Scipione, who became a landſcape painter of ſome eminence. If, as it is ſaid, they were living in Milan in 1718, they muſt have been very old. Lanzi, Storia Pittorica.

Cignaroli, Scipione, the ſon of the above-mentioned Martino, was a landſcape painter of ſome note; he is ſaid to have been the ſcholar of Cavalier Tempeſta (P. Molyn called Cav. Tempeſta died 1701) but owed great part of his advancement to the ſtudies which he made at Rome upon the works of Gaſpar Pouſſin and Salvator Roſa. From Rome he returned to Milan, where he painted many pictures which did him credit, till, having acquired conſiderable reputation, he was invited to the court of the duke of Savoy, where he lived in high eſtimation for the remainder of his life. Orlandi. Pilkington.

CIGOLI. See Ludovico *Cardi*.

CIGURRI, in *Ancient Geography*, a people of Spain who, according to Pliny, inhabited the country at preſent called Aſturia.

CILBIANA Juga, a mountain of Aſia Minor, in Lydia, in which was the ſource of the river Caiſter. It is mentioned by Pliny and Strabo.

CILBIANI, the name of a people who inhabited a country in Aſia Minor, near the Caiſter. As this country conſiſted partly of mountains, called "Cilbiana Juga," and partly of a plain, denominated "Cilbianus Campus," we may diſtinguiſh between thoſe who inhabited the former, called "Cilbiani Superiores" and thoſe who occupied the latter, contra diſtinguiſhed by the name of "Cilbiani Inferiores."

CILBICENI, a people of Spain, placed by Feſtus Avienus, in Bœtica, on the ſea coaſt, and in the vicinity of the town Tarteſſus: they occupied the banks of the river "Cilbus."

CILENDROS, an epiſcopal town of Aſia, in Iſauria.

CILENI, a people of Spain who inhabited the territory called Tarragonenſis. Ptolemy calls them Cilini, and aſſigns to them the town of "Udata Therma."

CILERY, in *Architecture*, a term uſed to denote the drapery or leavage on the heads of columns.

CILIA, in *Anatomy*, the hairs which are implanted on the borders of the eye-lids, and which in common language are termed eye-laſhes. See Eye.

CILIARIS Musculus, a few fibres of the orbicularis palpebrarum muſcle, which immediately ſurround the opening of the eyelids, and are deſcribed by Albinus, as a diſtinct muſcle, under the abovementioned name.

CILIARY Arteries, are branches of the ophthalmic artery,

artery, diſtributed to the choroid coat of the eye, and the iris. See Arteries.

Ciliary *ducts*, thoſe minute canals on the inner ſurface of the eyelids into which the Meibomian glands pour their ſebaceous ſecretion. See Eye.

Ciliary *proceſſes*, the folds on the inner ſurface of the anterior portion of the choroid coat of the eye, which adhere to the front of the vitreous humour. See Eye.

CILIATED, in *Botany*, a term applied to ſuch leaves and other parts of a plant as have their edges beſet with parallel hairs reſembling thoſe of the human eye-laſh.

CILIBÆ or Cillibæ, in *Ancient Military Language*, round tables, on which the Greek and Roman ſoldiers placed their bucklers, when they returned from any expedition.

CILICES, coarſe cloths woven or wrought of horſe-hair, and goats-hair, ſtitched and filled or ſtuffed with cow-hair or flocks of wool between every two of them, which the ancients ſtretched and ſuſpended before their parapets, ditches, and over breaches to ſtop arrows, darts, and ſtones thrown from *manubaliſtæ*, *baliſtæ*, or *catapultæ*.

CILICIA. See Cilicium.

Cilicia, in *Ancient Geography*, a country of Aſia Minor, lying between the 36th and 40th degrees of north latitude, and bounded by Syria on the eaſt, or rather by mount Amanus, which ſeparates it from that kingdom, by a chain of mountains that divided it from Piſidia and Pamphylia on the weſt, by Iſauria, Cappadocia, and Armenia Minor on the north, and by the Mediterranean on the ſouth. This country is ſo ſurrounded by ſteep and craggy mountains, chiefly the Taurus and Amanus, that it may be defended by a few men againſt a whole army; there being but three narrow paſſes leading into it, commonly called "Pylæ Ciliciæ," or the gates of Cilicia, one on the ſide of Cappadocia, called the paſs of mount Taurus, and the other two called the paſs of mount Amanus, and the paſs of Syria, leading from Syria. The Perſian army marched through the ſtraits of mount Amanus, while that of Alexander was encamped at Iſſus, not far from the ſtraits of Syria, which lie more to the ſouth, and were guarded by a body of Macedonians under the command of Parmenio: the ſtraits of mount Taurus Alexander had paſſed in entering Cilicia, the Perſians who guarded that paſs having retired at the approach of the Macedonians. The whole country of Cilicia was divided by the ancients into Cilicia Aſpera, and Cilicia Campeſtris. The former called by the Greeks Trachæa, or ſtony, is bounded by Iſauria on the north, Pamphylia on the weſt, Cilicia Campeſtris on the eaſt, and the Mediterranean on the ſouth. The cities mentioned by the ancients in this part of Cilicia are Sydra, or Syedra, Nagidus, Anemurium, Arſinoe, Celenderis, or Celandris, Aphrodiſias, Holmus, or Holmia, Sarpedon, Zephyrium, and Sebaſte. Theſe were the moſt noted towns on the coaſt of Cilicia Aſpera; the inland cities were Seleucia, Domitiopolis, Philadelphia, Lamus, and Scandeloro. The chief cities of Cilicia, properly ſo called, or Cilicia Campeſtris, were Soli, or Solæ, afterwards known by the name of Pompeiopolis, Tarſus, Anchiale, Anazarbum, Epiphania, Mopſueſtia, Iſſus, and Alexandria. The rivers of principal note in Cilicia are the Pyramus, the Cidnus, the Calycadmus, the Lamus, the Sarus, the Pyramus, and ſeveral others of leſs note, which water this province, and diſcharge themſelves into that part of the Mediterranean, called by the ancients the "Sea of Cilicia," and extending near 250 miles from eaſt to weſt. Cilicia Campeſtris is repreſented by Ammianus Marcellinus as one of the moſt fruitful countries of Aſia; but the weſtern part equally barren, though famous even to this day for an excellent breed of horſes, of which 600 are annually ſent to Conſtantinople for the uſe of the Grand Signior. The air in the inland cities is reckoned very ſalubrious, but equally dangerous on the ſea-coaſt, eſpecially to ſtrangers.

Joſephus ſays (Antiq. l. i. c. 7.), that this country was firſt peopled by Tarſhiſh, the ſon of Javan, and his deſcendants, whence the whole country was called Tarſis. The ancient inhabitants, it is ſaid, were, in proceſs of time, expelled by a colony of Phœnicians, who, under the conduct of Cilix, the ſon of Agenor, and brother to Cadmus, firſt ſettled in the iſland of Cyprus, and from thence paſſed into the country, which, from their leader, they called Cilicia. Strabo ſays (lib. xvii.), that this Phœnician colony paſſed from Cyprus into Phrygia, where they lived in ſubjection to the kings of Troy, and, after the Trojan war, poſſeſſed themſelves of that country, which was afterwards called Cilicia. Several colonies from other countries in ſubſequent periods ſettled in this kingdom; ſome, particularly, from Syria and Greece, whence the Cilicians in ſome places uſed the Greek tongue, in others the Syriac, but the former greatly corrupted by the Perſian, the predominant language of the country being a dialect of that tongue. Bochart derives the name of Cilicia from the Phœnician word "Challekim," or "Challukim," ſignifying a ſtone; that part of Cilicia, which the Greeks call Cilicia Trachæa, being very ſtony, and to this day called by the Turks, "Tes Wileieth," that is, the ſtony province.

The Cilicians, according to the relations of the Greek and Latin writers, were a rough race of people, unfair in their dealings, cruel, great liars, and in the Roman times, entirely addicted to piracy. Hence proceeded the proverbs, "Cilix haud facile verum dicit. Cilicium exitium;" and the ſaying of Pherecrates, "Dii ſemper nobis imponunt, more Cilicium," *i. e.* "A Cilician ſcarcely ever ſpeaks the truth. Cilician cruelty. The Goths, like the Cilicians, always deceive us."

The Cilicians, before they ſettled in the country now called Cilicia, occupied that diſtrict of Myſia, called alſo Cilicia, S. of the mountains that bound Dardania, and having to the weſt the gulf of Adramyttium. This was divided into "Cilicia Thebaica," and "Cilicia Lyrneſſia," after the names of the two cities, Thebes and Lyrneſſus. The firſt, ſituated to the north, was ſeparated from the ſecond, placed to the ſouth, by the river Evenus. At this time they were governed by kings. But after they ſettled in the other Cilicia, we find no mention of their kings till the time of Cyrus, to whom they voluntarily ſubmitted. They continued ſubject to the Perſians till the overthrow of that empire; but were governed to the time of Artaxerxes Mnemon by kings of their own nation. Herodotus, indeed, (l. iii. c. 90.) refers Cilicia to the claſs of Perſian Satrapies; but other writers (ſee Xenophon Cyropæd. l. vii. Diodor. l. xvi. Curt. l. ii.), lead us to conclude, that the Cilicians were governed by kings of their own in the time of Xerxes and Artaxerxes Mnemon. After the extinction of the Perſian empire Cilicia became a Macedonian province. On the death of Alexander it fell to the ſhare of Seleucus, and continued under his deſcendants till it was reduced by Pompey. As a proconſular province it was firſt governed by Appius Claudius Pulcher, and after him by Cicero, who reduced ſome ſtrong holds on mount Amanus, and for his ſucceſs was ſaluted by the army with the title of Imperator, or general. The whole of Cilicia being thus brought under ſubjection, it was at firſt divided into Cilicia Campeſtris and Trachæa; the former became a Roman province, but the latter was governed by kings appointed by the Romans till the reign of Veſpaſian, when this part was alſo made a province of the empire, and the whole divided into Cilicia Prima, Cilicia Secunda, and Iſauria. The firſt comprehended the whole of Cilicia Campeſtris; the ſecond included the coaſt of Cilicia Trachæa; and the laſt the inland parts of the ſame diviſion; and in this ſtate

it

it continued till the division of the empire. In Cilicia Prima there were eight episcopal sees, viz. Tarsus, Pompeiopolis, or Soli, Sebaste, Corycus, Adana, Aguria, or Augustopolis, Malchus, or Malus, and Zephyrium. The episcopal towns of Cilicia Secunda were the following nine, viz. Anazarba, Rosus, or Rossus, Mopsuestia, Ægæ, Epiphania, Alexandria, Irenopolis, Flavias, and Castabala.

Cilicia is now a province of Caramania, bounded on the N.W. by the long ridge of mountains which separates it from Isauria and Lycaonia; on the N. by Cappadocia and Lower Armenia; on the E. by Comagene; and on the S. by Syria and the Mediterranean. The eastern part, as we have already observed, is a fine flat fertile country; the other very hilly, rocky, and barren. The Cilicians were the inventors of a kind of manufactory of hair-cloth, chiefly of goat's-hair, called sack-cloth, and much used in the penitentiary humiliations of the Jews and primitive Christians. Adana is much resorted to from other towns of Cilicia, especially from the mountain side, for its wines, corn, and other fruit, hence dispersed into the most barren parts.

CILICIA is also a country and province of Cappadocia. Ptolemy says that it is the name of a prefecture, or military government.

CILICIA *Terra*, in the *Natural History of the Ancients*, a bituminous substance, though called an earth, which, by boiling, became tough like bird-lime, and was used instead of that substance to cover the stocks of the vines, for preserving them from the worms. It probably served both to drive those animals away by its nauseous smell, and entangle them if they chanced to get among it.

CILICIUM, a sort of habit made of coarse stuff, of a black or dark colour, formerly in use among the Hebrews, in times of mourning or distress. It was called *Cilicium*, because it came from Cilicia, or rather because the Cilicians invented this kind of habit, made of goat's hair, and used principally in camps and ships, by soldiers and mariners.

CILICIUM *Mare*, in *Ancient Geography*, a name given by the ancients to that part of the Mediterranean sea, which bathed the coasts of Cilicia. Pliny calls it "Cilicius Aulon."

CILICIUM *Insula*, the name of an island in the Euxine sea, in the Pontus-pelamoniacus, 15 stadia from the promontory of Jason, according to Arrian.

CILIMBENSII, a people placed by Ptolemy in the northern part of the island of Corsica.

CILINA, or CÆLINA, a town of Venetia, towards the north.

CILISARUM, or CILIZA, a town of Asia in Syria, between Cyrrhæ and Edessa. See Itinerary of Antonine.

CILIUM, an episcopal town of Africa, in the Byzacene.

CILIZA, a town of Asia in Syria, situated near the mountains on a stream W. of Deba.

CILLA, a town of Asia Minor in Ætolia, according to Herodotus. From Strabo, it appears that this town was at the foot of a mountain of the same name.—Also, a town of Africa Propria, according to Appian. It was episcopal.

CILLABA, a town of Africa, situated towards the deserts beyond the lesser Syrtis.

CILLÆ, or CELLÆ, a town of Thrace upon the route from Rome to Constantinople, between Philippopolis and Opizum; according to the Itinerary of Antonine.

CILLENE, a mountain of Arcadia, said to be the highest in the whole country.

CILLEUS FLUVIUS, a river of Asia Minor, which had its source in mount Ida, ran near a place named Cilla, before the town of Thebes in Cilicia.

CILLEY, in *Geography*, a town of Germany, in the duchy of Stiria, on the river Saan, and capital of a district, which extends as far as Pettaw. The inhabitants, who speak German and Sclavonian, are said by some to have been brought hither by the duke of Bavaria to oppose the Romans. Cilley is said to have once belonged to the Romans, and afterwards to have been destroyed; but when it was given by Lewis, the old king, and duke of Bavaria, to Hezillon, duke of Moravia, he re-built it. The district, or Comté, was once an independent principality; and governed by its own counts; 130 miles S.S.W. of Vienna. N. lat. 46° 21′. E. long. 15° 16′.

CILLUTA, in *Ancient Geography*, an island of the Indian Ocean, mentioned by Arrian, (l. vi. c. 19.) that seems to have been situated in the principal mouth of the river Indus; it was of considerable extent, and had several commodious ports.

CILMA, or OPPIDUM CHILMANENSE, now *Gelma*, a town of Africa, in Byzacium, situated 6 leagues to the E. of Sufetula; it appears to have been a large city, and has the area of a temple still remaining.

CILNIANA, CILMANA, CILUANA, or SILVIACA, a place of Spain, in Bœtica, between Gades and Calpé. M. D'Anville marks it in his chart upon the sea-coast, in the country of the Bastuli, S. of Munda.

CILOCA, in *Geography*, a town of South America, in Peru, on the coast of the Pacific Ocean; 40 miles W. of Arequipa.

CILURNUM, WALWICK-CHESTERS, the sixth station on the wall of Severus, in Britain, according to the Notitia Imperii. See STATION.

CIMA, in *Architecture*. See CYMA.

CIMABUE, GIOVANNI, in *Biography*, an Italian painter, who is generally honoured with the appellation of the father of modern painters; but although the arts of design have the greatest obligations to this extraordinary man, who first emerged from that hereditary barbarism of style, which for so many centuries had marked the wretched efforts of European painters; yet, it is equally certain, that, without any reference to the Greek artists who are supposed by Vasari to have been the masters of Cimabue, Italy for at least two or three centuries prior to the period of Cimabue's birth, had constantly possessed artists, and artists of her own, sufficiently instructed, to paint the miserable and ghost-like objects of superstition and devotion. See PAINTING, *History of*.

Cimabue, according to the authority of Vasari, was born of a noble family in Florence, in the year 1240, and, at a very early period, having evinced a strong desire and genius towards the art, was put under the tuition of some Greek painters, who were at that time employed to paint a chapel under the church of St. Maria Novella. These he quickly surpassed, and gave such striking proofs of his superior talents, that he soon became employed in the most considerable undertakings.

Of his numerous works at Florence little now remains, except his celebrated Madona, larger than the life, at St. Maria Novella; and another at the church of St. Trinita: they are both painted in distemper, and well preserved. The former of these works was considered, when finished, so extraordinary an effort of the pencil, that Vasari informs us it was carried in procession, accompanied by trumpets, from the house of the painter to the church; which circumstance, together with other rejoicings on the occasion, caused the street through which the picture passed to be called, as it is to this day, "Il Borgo Allegri." But an adequate idea of the genius of Cimabue can alone be formed by examining his decayed frescoes still remaining in the church of St. Francesco of Assini. Here, on one side of the church, he painted in sixteen compartments, with figures something larger than life, the histories of the Old Testament, from the creation of the world, to the story of Joseph and his Brethren; and on the opposite side the same number of stories from the New Testament, beginning with the Annunciation, and ending with the Resurrection; besides the four Doctors of the Church, and many other figures on the ceiling, and several stories from the Revelations in other parts of the church.

church. Although the greater part of these pictures has suffered greatly from the destructive hand of time, yet several of them are tolerably, and some of them perfectly preserved; and are, notwithstanding the rudeness of their execution, in so grand and so simple a style, as to strike with astonishment the traveller who has been taught to expect in the first efforts of the art nothing beyond the humble and imperfect attempt of servile imitation. Some of the conceptions and compositions in this work would not do discredit to the genius of Raffaele at an early period, and certainly possess an energy and boldness of expression far surpassing the tame though careful performances of his master, P. Perugino: and although Giotto and his followers, who immediately succeeded Cimabue, gave a greater softness and variety to their draperies, and more diversity in the characters and expressions of their heads, yet it is difficult to find instances in their works where the naked parts of the figure are so well drawn, as in some of the above-mentioned compositions. He died aged 60 in the year 1300. Vasari. Lanzi, Storia Pittorica, MS.

CIMAEON Mons, in *Ancient Geography*, a mountain of Asia Minor, placed by Ptolemy towards the Troade. It was probably the chain of mountains that separated the Troade from the country of the Lelegi.

CIMARA, a town of India, on the other side of the Ganges, according to Ptolemy.

CIMAROSA, Dominico, in *Biography*, maestro di cappella to the king of Naples, was a native of that capital, born at Capo di Monte; he studied music at the conservatorio of Loretto, and was a disciple of the admirable Duronte. He was carefully educated in other respects, and his docility and sweetness of temper, during his youth, gained him the affection of all who knew him. On quitting the conservatorio his talents were soon noticed, and his operas, chiefly comic, became the delight of all Italy. But though he composed for buffo singers, his style was always graceful, never grotesque or capricious. There is an ingenuity in his accompaniments which embellishes the melody of the voice part, without too much occupying the attention of the audience. His operas of "Il Pittore Parigino," and "L'Italiana in Londra," were carried to Rome, and thence to the principal cities of Italy, where their success was so great in 1782 and 1783, that he received an order from Paris to compose a cantata for the birth of the Dauphin, which was performed by a band of more than 100 voices and instruments. In 1784 he was engaged to compose for the theatres and cities which seldom had operas expressly composed for them; bringing on their stage such as were set for great capitals, such as Rome, Naples, Venice, and Milan. By these means the expences of poet and composer were saved. Cimarosa's success and fame were more rapid than those of any composer of the last century, except Piccini, and the fame of his comic opera of "L'Italiana in Londra," seems to have been as extensive as that of the "Buona Figliuola."

In 1787 he succeeded Sarti at Petersburg, and composed several operas for that court. The same year he furnished Milan with the comic opera of "Le Trame Deluse," and in 1788, with that of "Il Fanatico Burlato;" though he remained in Russia till 1790; when he went to Madrid, for which capital he composed two operas, one serious, intitled "La Virgine del Sole," and one comic, "Il Fanatico Burlato." In 1792, we believe he was at Vienna, where he produced two of his operas, both comic; one, "Le Trame Deluse," composed in 1787, and "Il Matrimonio Segreto." We find but few serious operas by Cimarosa. "Giunio Bruto" seems to have been the first, and "Ines di Castro," and "La Vendetta di Mino," for Spain, with "Penelope" for Naples, the last. His latter comic operas were, "Amor Rende Sagace," for Vienna; "I Fraci Amanti," and "Le Artuzie Femminile," both for Naples, in 1794. "L'Impegno Superato," with "L'Impresario in Angustia," both likewise for Naples, 1795; and "I Nunici Generosi," for Rome, 1796.

We are acquainted with his productions no further. Italy was in such a revolutionary confusion in subsequent years, that no art seems to have been cultivated there but that of war and its concomitants, rapine and slaughter.

Cimarosa, unfortunately for his fame and fortune, manifested a partiality for the French during their possession of Naples, which occasioned his disgrace at the court of his patron and natural sovereign, and he narrowly escaped the fate of convicted rebels and traitors. He was however allowed to die in his bed in 1801, in the 50th year of his age, extremely regretted by the lovers of music, as an original and exquisite composer, and an amiable man, of so obliging and sweet a temper, that being uncommonly corpulent, his immense size was ascribed to his good humour and placid disposition.

CIMARUS Promontorium, in *Ancient Geography*, a promontory which was situated, according to Strabo, on the northern coast of the isle of Crete.

CIMBINA, or Cibina, a town of Asia, in Media.

CIMBIS, a maritime place of Spain, which, according to Livy, was situated in the vicinity of Gades.

CIMBRI, the most northern people of Germany, mentioned by Pliny, Strabo, Mela, Tacitus, and Plutarch; but they are not agreed with respect to their origin; some tracing them to the Scythians, and others to the Cimmerians. They anciently occupied the peninsula which stretches out into the German sea and known under the name of the Cimbric Chersonesus. (See Chersonesus *Cimbrica.*) About the year 645 of Rome they left their own country, and joining the Teutones, Ambrones, and Tigurians, ravaged part of Germany, Helvetia, and the Lyonnese and Narbonnese Gauls, and penetrated into Italy. In their progress they defeated the Romans in several pitched battles, and threw Italy into the greatest consternation. In the first of these actions they vanquished the consul Papyrius Carbo; in another they defeated M. Junius Silanus, another consul, who was called to a severe account for his bad success; in the third, L. Cassius; and in a fourth, the brave M. Aurelius Scaurus, whom they took prisoner and put to death, by order of their king, Bolos, for speaking too warmly in praise of the Romans. However, after several other successes in Italy, during a war of eight years, they were totally defeated and destroyed by the valour and policy of Marius and Catulus, A. U. C. 653, as they were endeavouring to enter Italy through Noricum, now the Tyrol; 120,000 being killed and 60,000 taken prisoners. How highly the Romans estimated this victory may be deduced from the triumph and other singular honours which they decreed both to Marius and to Catulus, as well as from the monuments which these caused to be erected in memory of this transaction. Those Cimbri, who escaped the dreadful slaughter, probably returned into their own country; for they are said to have afterwards sent a submissive embassy to Augustus, and are likewise mentioned by authors of later date, as the most warlike of all the northern Germans, down to Claudian's time, who calls the North Sea by their name; but their name was sunk either in that of the Teutones, or of the Saxons, who, being their neighbours, joined with them in their excursions, and gradually became more powerful.

The Cimbri, supposed by Mr. T. Warton to be a Scandinavian tribe, and by others to be the northern Celts, the ancestors of the Welsh, called Cymri, were accompanied at their assemblies by venerable and hoary-headed prophetesses, apparelled in long linen vestments of splendid

did white. Their matrons and daughters acquired a reverence from their skill in studying simples, and their knowledge of healing wounds, arts reputed mysterious. The wives frequently attended their husbands in the most perilous expeditions, and fought with great intrepidity in the most bloody engagements. These northern nations dreaded captivity more on the account of their women than on their own; and the Romans availing themselves of this apprehension, often demanded their noblest virgins for hostages. Tacit. de Mor. Germ. cited by Warton. Hist. of English Poetry, vol. i. diss. i.

CIMBRIANÆ, a place of Mœsia, on the route from Sirmium to Carnuntum, between Tricciana and Crispiana, according to the Itinerary of Antonine. The Notitia Imperii places it under the department of the second Mœsia.

CIMBRISHAMN, or CIMBRISHAVEN, in *Geography*, a sea-port of Sweden, in West Gothland, and province of Schonen; 24 miles S. of Christianstadt.

CIMEGES, a town of France, in the department of the Dordogne, and district of Bergerac; 7 miles S.W. of Bergerac.

CIMELIANTHUS, in *Natural History*, a name given by authors to a species of the *oculus beli*. It is described to be of a white colour, resembling that of marble, with a yellow pupil in the middle. It was found on the shores of the Euphrates.

CIMELIARC, in *Church Architecture*, the room where the plate, vestments, &c. belonging to the church are kept. In English, a vestry.

CIMELOS, in *Ancient Geography*. See CIMOLUS.

CIMETERRE. See SCIMITAR.

CIMETRA, in *Ancient Geography*, a town of Italy in the country of the Samnites, taken by Fabius in the year of Rome 455. Livy.

CIMEX, in *Entomology*, a genus of hemipterous insects. Linnæus defines the genus cimex in the following manner. Rostrum or snout inflected; antennæ longer than the thorax; wings folded together cross-wise; the wing-cases coriaceous on the upper part; back flat; thorax margined; legs formed for running. These he divides into many sections. The first, *apteri*, are those without wings as in the common house-bug. The *scutellati*, those in which the escutcheon is extended so far as to cover the abdomen and wings. The *coleoptrati* have the wing-cases entirely coriaceous instead of having the extremity membranaceous as in the other cimices. The *membranacei* have, on the contrary, the wing-cases entirely membranaceous, and are much depressed. The *spinosi*, those which have the thorax armed each side with a spine. The *rotundati* are of an oval form, without spines on the thorax. The *seticornes* have the antennæ setaceous towards the tip. The *oblongi* are of an oblong form. The *spinipedes* have the thighs armed with spines; and the *lineares* have the body of a linear form.

Linnæus could not be aware of the amazing extent of the cimex genus as he had instituted it. The number of insects possessing the same characters which he proposed for the cimices that were known to him were comparatively few, amounting perhaps at the utmost to scarcely more than a tenth portion of those described since his time by various writers. With such scanty materials Linnæus found it sufficient for his purpose to dispose of insects very different in other respects, though according with his generic character, to some one of the sections he had formed, or to frame a new section for its admission. But considering the prodigious number of new species of this tribe that have been recently discovered, it will be found, we are persuaded, that the Linnæan genus is no longer adequate to the reception of the whole. Insects possessed of such very dissimilar characters, though truly Linnæan cimices, if brought together under a single genus, would present a most incongruous assemblage. Fabricius has been assiduous in the formation of new generical improvements in this tribe; he has availed himself of the discoveries of naturalists and collectors of the present time, and has been able by that means to introduce to our acquaintance many hundred species of this tribe that were before unknown. Fabricius constitutes of the Linnæan cimices seven distinct genera, acanthia, cimex, coreus, lygæus, miris, gerris, and reduvius. We are not the partizans of innovation on any established system, and above any other of that originally founded by Linnæus; but we really think it might be right to constitute even a still further number of genera than Fabricius has done to include the whole of those insects which stand as Cimices in the Linnæan system. But whatever may be our ideas in this respect, we shall, for the present, pursue only a middle line, retaining, somewhat after the manner of Gmelin, some of the Fabrician genera, as sub-divisions of the Linnæan cimices, and allowing others, which we think ought absolutely to stand as genera distinct from Cimex, to form an appendage to our article. It will be thus perceived, that in the Linnæan arrangements, the whole are Cimices, and in the Fabrician system so many distinct genera.

Genus *Cimex*. Linn.—Genus *Acanthia*. Fabr.

Species.

LECTULARIUS. Apterous; body ferruginous. Linn. *Acanthia lectularia*, Fabr. Common house bug. The history of this fœtid and nauseous insect is well known; it is the inhabitant of most houses; crawls from its lurking places in walls and furniture to suck the blood of those that are asleep during the night, in the day conceals itself; it is said to have an aversion to elder and tobacco. Scopoli pretends that it has been found with wings, some account of which seems to have been published in an old German pamphlet, but we cannot credit the assertion of the writer.

ATER. Glossy black; thorax with a white dorsal line. *Acanthia atra*, Fabr. Inhabits Germany.

ZOSTERÆ. Black; wing-cases coriaceous, and as long as the abdomen; tip hyaline and striated. Fabr. Inhabits Germany.

FLAVIPES. Black; wing-cases coriaceous, as long as the abdomen, and immaculate; legs pale. Fabr. Inhabits Saxony. C. *Saxonicus*, Gmel.

PALLICORNIS. Black and glossy; wing-cases coriaceous, abbreviated, and without spots; antennæ and legs pale. Fabr. Inhabits Saxony.

GRYLLOIDES. Apterous, black; thorax and wing cases margined with white. Fabr. C. *grylloides*, Linn. Inhabits Germany.

CORIACEUS. Apterous; shells coriaceous, black-grey. *Acanthia coriacea*, Fabr.

CLAVIPES. Apterous; black; legs pitchy; anterior thighs thickened and dentated. Fabr. Inhabits Tranquebar.

NIGRICORNIS. Black; anterior part of the thorax greenish; wing-cases coriaceous and greenish. Fabr. C. *nigripennis*, Gmel. Inhabits Germany.

CLAVICORNIS. Wing-cases with reticulated punctures; antennæ clavated. Panzer. Inhabits Germany.

CRASSICORNIS. Wing-cases dusky ash; extreme joint of the antennæ compressed and lanceolate. Fabr. Inhabits Germany.

VIRESCENS. Greenish; last joint of the antennæ ovate, thick, and black. Fabr. Inhabits the South American islands.

LAVATERÆ. Black; wing-cases and abdomen at the base rufous. Fabr. A native of Barbary.

SERRATULÆ. Black; wing-cases palish; tip of the wings fuscous. Fabr. Found in England.

FASCIATUS. Black; wing-cases palish, with two abbreviated black bands. Fabr. A native of Germany.

MACULATUS.

Maculatus. Brown; thorax with three white ſpots; abdomen beneath white, the edge dotted with black. *Acanthia maculata*, Fabr. Inhabits Tranquebar.

Pallipes. Black; wing-caſes pale with black baſe and marginal ſpot. Fabr. C. *marginalis*, Gmel.

Littoralis. Wing-caſes ſordid grey with white dots; body black. Fabr. Inhabits the north of Europe.

Rugosus. Wing-caſes pale; body oblong; anterior thighs very thick. Linn. A. *rugoſa*, Fabr. A native of North America.

Lunatus. Thorax lunate, with prominent margin: abdomen ſerrated. A. *lunata*, Fabr. An Indian ſpecies.

Corticalis. Membranaceous; abdomen imbricated at the ſides; body black. Fabr. Inhabits Europe. *Cimex corticalis*, Linn.

Depressus. Membranaceous; fuſcous; thorax with four elevated lines; wing-caſes white, with a raiſed fuſcous ring. *Acanthia depreſſa*, Fabr. Inhabits Germany.

Planus. Membranaceous, black; thorax with four raiſed black lines; wing-caſes, and wings white, ſpotted with black. *Acanthia plana*, Fabr. Inhabits Saxony.

Paradoxus. Membranaceous; thorax and abdomen lobated and ciliated with ſpines. Sparrman act. Holm. 1777. Inhabits the Cape of Good Hope, and reſembles a dead leaf.

Lævis. Black; abdomen ſmooth and brown; wings pale. Fabr. An Engliſh inſect.

Betulæ. Membranaceous; thorax denticulated; head ſpinous; anterior part of the wing-caſes dilated. Linn. A native of Europe.

Grisatus. Depreſſed, grey; abdomen beneath with a black ring. *Acanthia griſea*, Fabr. Found in Barbary.

Erosus. Membranaceous, abdomen yellow with black band; margin of the thorax ſinuate; anterior ſhanks thick. Linn. *Cimex Scorpio*, Degeer. A native of Surinam.

Monstrosus. Membranaceous, black; abdomen ſerrated, angular with white tip; head and thorax ſerrated; anterior ſhanks thickened. A. *monſtroſa*, Fabr. A native of Barbary.

Gibbus. Black; ſcutel and wing-caſes white, with a black dot at the tip. A. *gibba*, Fabr. Inhabits the Eaſt Indies.

Campestris. Black; wing-caſes white with fuſcous tip, and whitiſh ſpot; wings without ſpots. Fabr. Inhabits New Zealand.

Nemoralis. Black; wing-caſes with a white dot in the middle; wings fuſcous, at the baſe white. Fabr. Inhabits Zealand.

Pratensis. Black; wing-caſes yellowiſh, tip duſky; wings white with fuſcous ſpot at the tip. Fabr. Inhabits Germany.

Sylvestris. Black; wing-caſes white, with a black arch at the tip. Linn. Found in woods in Europe.

Alatus. Thorax with four raiſed fuſcous lines; wing-caſes pale, with a fuſcous ſpot at the tip. Fabr. Inhabits Sweden.

Costalis. Thorax with three raiſed lines; body brown; rib of the wing-caſes dotted with black and white. Fabr. An European inſect.

Sacchari. Thorax and ſcutel with three raiſed lines; body brown; wings hyaline and reticulated at the tip. Fabr. Inhabits South American iſlands.

Cardui. Thorax and ſcutel with three raiſed lines; tip of the antennæ black. Fabr. A native of Europe.

Humuli. Thorax with three raiſed lines; the margin very thick; body beneath black, legs rufous. Fabr. Inhabits Germany.

* *Scutel as long as the abdomen.*

Stockerus. Ovate; body green, with black ſpots; abdomen ferruginous. Linn.

Inhabits China. Donov. Inſ. China. Beneath ferruginous, at the ſides blue; colour above variable from gloſſy-green to blue.

Eques. Ovate; body green, with black ſpots; abdomen deep black; margin green, with black dots. Fabr.

Smaller than the preceding. Deſcribed from a ſpecimen in the cabinet of Lund, received from Tranquebar. We have ſeen the ſame from Africa.

Nobilis. Oblong, blue, gloſſed with golden, and ſpotted with black. Linn.

An Aſiatic inſect, much reſembling *Cimex ſtockerus*, but of a more oblong form, and far more rare.

Signatus. Oblong; thorax and ſcutel bluiſh, with ſix black ſpots. Fabr.

A native of Senegal, in the cabinet of Rouſſillon. Reſembles the preceding ſpecies.

Regalis. Thorax golden, with two bluiſh dots; ſcutel golden, with two bluiſh ſpots. Fabr. A native of New Holland. Donov. Inſ. N. H. Very rare.

Imperialis. Thorax and ſcutel rufous; abdomen blue; with a ſanguineous margin. Fabr.

Inhabits the ſame country as the preceding. Donov. Inſ. New Holland.

Banksii. Violaceous; on the thorax an anchor-ſhaped ſpot, with two curved lines, and three ſpots on the ſcutel ſanguineous. A new ſpecies. Donov. Inſ. New Holland.

Carinthis. Dull black, and without ſpots. Fabr. Inhabits Africa.

Dispar. Red, or fleſh colour; thorax and ſcutel with yellow ſpots, ſome containing a black pupil or dot. Fabr. Donov. Inſ. China. *Cimex ocellatus*, Thunberg.

Nigellæ. Dull black; anterior part of the thorax, edge of the abdomen, and legs white. Fabr. A native of Barbary. Found on the Nigella.

Annulus. Greeniſh, with black annular ſpots. Fabr. *Cimex argus* of Drury's Exotic Inſects. Inhabits Senegal.

6-Punctatus. Above teſtaceous; thorax with four; ſcutel with two black-blue dots. Fabr.

Deſcribed from the Hunterian Cabinet. Inhabits South America.

Arcuatus. Grey; thorax and ſcutel with two black curves. Fabr. A native of South America.

Druræi. Above red, with large irregular black ſpots. Drury Inſ. Inhabits America.

Fabricii. Somewhat purpliſh, with fulvous dots. Fabr. Inhabits Cayenne.

Argus. Black, with numerous ocellar fulvous ſpots. Stoll. Reſembles the former. Inhabits Surinam.

Schulzii. Braſſy black; ſcutel with a ſcarlet ſpot on each ſide at the baſe. Fabr. Found in Cayenne.

Paganus. Azure; ſcutel and abdomen rufous, with azure ſpots. Fabr. Donov. Inſ. New Holland. Bankſian Cabinet.

Illustris. Glaucous; thorax and ſcutel with two fuſcous dots. Fabr. Inhabits the Cape of Good Hope.

Furcifer. Brown; ſcutel with two black dots, and tridentated fulvous ſpot behind. Stoll. Cab. Holthyſen. Same country as the preceding.

Lineola. Above blue; head and thorax with a dorſal line of red, and two dots of the ſame colour on the ſcutel. Fabr. Inhabits the Cape of Good Hope.

Trilineatus. Black, with three yellowiſh lines. Fabr. Inhabits South America.

NIGROLINEATUS. Red; thorax with five black lines; ſcutel with three; abdomen yellow, dotted with black. Fabr. Inhabits South of Europe. Linn.

SEMIPUNCTATUS. Above rufous; thorax with ten black dots; ſcutel with four lines of black. Fabr. Inhabits America.

SILPHOIDES. Braſſy-black; margin of the abdomen beneath, and legs yellow. Fabr. A native of India.

ANCHORAGO. Azure; ſcutel at the baſe and tip yellowiſh; margin of the abdomen yellow, dotted with black. Solander. Inhabits America.

GRAMMICUS. Body yellowiſh, with a black longitudinal litural mark or daub. Linn. A native of Africa.

PÆDEMONTATRUS. Rufous, with numerous white ſpecks. Fabr. *Cimex allioni*, Gmel. An Italian ſpecies.

COSTATUS. Grey; rib of the wings at the baſe and the legs rufous. Fabr. Donov. Inſ. New Holland. A ſpecimen in the Bankſian Cabinet was found in Rotterdam Iſland.

HOTTENTOTTA. Ferruginous, and immaculate. Fabr. Inhabits the Eaſt. Prof. Forſkahl.

MAURUS. Cinereous; ſcutel with two white dots at the baſe. Linn. A native of the ſame part of the world as the preceding.

LYNCEUS. Duſky teſtaceous, dotted with black; ſcutel with two fulvous dots at the tip. Fabr.

ALBO-LINEATUS. Thorax ſomewhat ſpinous, grey, and ſtriated with white. Fabr. A native of Italy. Dr. Allioni.

RUSTICUS. Fuſcous; head and anterior part of the thorax ferruginous; beneath varied with white, and fuſcous.

IRRORATUS. Greeniſh, ſpeckled with fuſcous. Fabr. A native of America.

LANATUS. Braſſy-black, with grey hairs. Pallas. Inhabits Siberia.

GLOBUS. Globoſe, gloſſy-black; margin of the abdomen ferruginous. Fabr. Inhabits the ſouth of Europe.

SCARABÆOIDES. Body entirely braſſy. Linn. Found on flowers of the ranunculus.

PALLIPES. Braſſy-black; margin of the ſcutel, and abdomen, with the legs pale. Inhabits Africa. *Cimex acaroides*, Thunberg.

FLAVIPES. Braſſy-black; whole margin, and the legs yellow. Fabr.

Deſcribed from a ſpecimen in the Bankſian Cabinet. Inhabits New Holland.

DESFONTAINII. Thorax ſpinous; above grey, beneath whitiſh. Fabr. Inhabits Barbary.

FULIGINOSUS. Scutel ſooty, with five black litural marks or blotches, the poſterior one white. Linn. Inhabits Europe.

VAHLII. Gloſſy black; head with two yellowiſh blotches; margin of the thorax, ſcutel, and legs yellow. Fabr. Inhabits the Eaſt.

TUBERCULATUS. Duſky; ſcutel ſcabrous, before the tip tuberculated. Fabr. A native of Italy.

LITURA. Black; two ſmall yellow lines at the baſe, and dot at the tip white. Fabr. Inhabits Arabia according to Forkſkahl.

INUNCTUS. Black; ſcutel at the baſe, with the legs grey. Fabr. An Engliſh ſpecies.

ARABS. Thorax ſpinous; body ovate, livid; tail bidentated. Linn. Found in American iſlands.

STOLIDUS. Thorax ſomewhat angulated; body above green, beneath yellow; tail armed with two teeth. Linn. An Indian ſpecies.

* *Thorax ſpinous each ſide.*

CERVUS. Green; wing-caſes fuſcous, with white margin; ſpines of the thorax obtuſe, and ſomewhat bifid. Stoll. A native of Cayenne.

TAURUS. Grey; ſpines of the thorax advanced, compreſſed, and truncated. Fabr. Inhabits the Coromandel coaſt.

DAMA. Grey; ſpines of the thorax obtuſe and emarginate. Fabr. This is of a large ſize and inhabits the Eaſt Indies.

VACCA. Olive; thorax obtuſely ſub-ſpinous; antennæ rufous at the baſe; ſternum ſhort and compreſſed; tail armed with four teeth. Fabr. A large ſpecies. This inhabits Guadaloupe.

GAZELLA. Thorax obtuſely ſub-ſpinous; above greeniſh; head and anterior part of the thorax yellowiſh; abdomen ſerrated. Fabr. Inhabits Martinique. Iſert.

TARANDUS. Thorax ſpinous, above blue-black; anterior margin of the thorax, three dorſal lines, and tip of the ſcutel white. Fabr. A ſpecies of large ſize, deſcribed from an inſect in the Britiſh Muſeum. Native country unknown.

BIDENS. Spines of the thorax ſharp; body grey; antennæ rufous. Linn. Found in gardens in Europe.

SANGUINIPES. Spines of the thorax obtuſe; body fuſcous; ſcutel at the tip whitiſh; ſpots on the margin of the abdomen and legs black. Fabr. Inhabits Italy.

RUFIPES. Spines of the thorax obtuſe; body grey; legs rufous. Linn. Inhabits Europe. Found in Gardens.—*Obſ.* In ſome ſpecimens the tip of the ſcutel is rufous.

LURIDUS. Spines of the thorax obtuſe, greeniſh; wing-caſes grey with a fuſcous ſpot; ſhield emarginate. Fabr. Deſcribed by Fabricius as an Engliſh inſect on the authority of the Bankſian cabinet. Taken in woods near London, but rare. Donov. Brit. Inſ.

CUSTOS. Thorax obtuſely ſpined, grey; antennæ yellow, with two black annulations. Fabr. A native of Germany.

NIGRICORNIS. Thorax obtuſely ſpined, ſub-ferruginous; ſpines and antennæ black. Fabr. A native of Saxony.

NIGRISPINUS. Thorax obtuſely ſpined; above grey; head and ſpines black; antennæ with a black ring. Fabr. Inhabits China.

ICTERICUS. Oblong; above reddiſh; beneath yellow. Linn. Amœn. Acad. Inhabits America.

PUNCTATUS. Thorax ſomewhat ſpinous; fuſcous, abdomen variegated at the margin; ſhanks with a white ring. Fabr. A native of Europe, ſometimes found in England.

VARIUS. Thorax obtuſely ſpined; above rufous, beneath yellowiſh; ſcutel black, with the baſe and tip white. Fabr. Inhabits Spain. Vahl.

LUNULA. Thorax obtuſely ſpinous; above rufous; on the anterior part of the thorax five little yellow lines; two lunules at the baſe of the ſcutel, and the tip white. Fabr. Inhabits Barbary.

ALBIPES. Thorax ſomewhat ſpinous; above blackiſh; margin of the thorax and ſcutel tip white. A Fabrician ſpecies deſcribed from the cabinet of Dr. Allioni. A native of Italy.

DENTATUS. Thorax ſlightly ſerrated; body varied with cinereous and black. Fabr. An Eaſt Indian ſpecies.

FLORIDANUS. Black, varied with red; ſcutel with three red ſpots, Linn. A native of America.

ARMATUS. Spines of the thorax acute; ſcutel black, two dots and tip teſtaceous; antennæ and legs red. Fabr. Inhabits New Holland. Bankſian cabinet.

HÆMORRHOUS. Black; abdomen rufous; wing-caſes, with five black linear dots. A Linnæan ſpecies. Inhabits America.

2-PUSTU-

2-Pustulatus. Black; wing-cases livid; head with two scarlet dots. Linn. A native of Surinam.

Punicus. Black; lunule on the scutel, and tip red. Linn. An African insect.

Ypsilon. Livid; scutel with a yellow y-like mark. Linn. Found in Surinam.

Clypeatus. Green, with yellowish band; head shielded. Fabr. A native of China. Gronovius.

Elector. Above grey, beneath yellowish, with black dot; antennæ black; band before the tip yellow. Fabr. Country unknown.

Albicollis. Thorax dentated; above green; head, fore part of the thorax, and base of the scutel yellow. Fabr. *Cimex flavicollis*, Drury. A native of Jamaica.

Hæmorrhoidalis. Thorax obtusely spinous; somewhat greenish; antennæ black; sternum projecting, Linn. An European species. Found in England, Donov. Brit. Inf. &c.

Spinideus. Spines of the thorax acute; fuscous; scutel at the tip and margin of the upper wings white. Fabr. Found in Tranquebar.

Sagittata. Thorax acutely spined and serrated; grey; under-wings with a black fillet; antennæ and legs yellow. Fabr. Inhabits South American islands.

Oculatus. Grey; scutel with two yellow dots; anterior tarsi of the legs compressed and membranaceous. Fabr. A native of China.

Annulatus. Grey; shanks annulated with white. Fabr. A native of Virginia.

4-Pustulatus. Thorax obtusely spined, and crenated, with two rufous dots; scutel with two rufous dots at the base. Fabr. An American species.

Maculatus. Greenish; thorax obtusely spined, with four brown spots; tip of the scutel and wing-cases brown. Fabr. Same country as the former.

Pugnax. Thorax acutely spined, oblong and greenish; antennæ rufous. Fabr. Inhabits America.

Emeritus. Thorax acutely spined, greenish; abdomen with two lines of white. Fabr. A New Holland species in the Banksian cabinet.

Gladiator. Thorax acutely spined, and with the scutel yellow dotted with black; wing-cases rough with white dots. Degeer, &c. An American insect.

Ferrugator. Thorax acutely spined; above grey; head and spines black; abdomen ferruginous, Paykull, &c. Inhabits Sweden.

Crenator. Thorax crenated; above grey, beneath yellowish. Fabr. A native of the American islands. Smidt.

Furcatus. Thorax acutely spined and serrated; fuscous; shield of the head acuminated and bifid. Fabr. Described from an insect in the Banksian Cabinet, found on the coast of Patagonia.

Pugillator. Thorax acutely spinous; fuscous; margin yellow, beneath fulvous dotted with black. Fabr. Inhabits Africa.

Perditor. Thorax acutely spinous, with two dots and band in the middle brown; margin of the abdomen varied with fulvous and green. Fabr. Inhabits American islands.

Victor. Thorax acutely spined; fuscous; tip of the scutel rufous; legs pale, dotted with black. Fabr. Inhabits American islands.

Delirator. Thorax acutely spined; black; antennæ ferruginous; legs pale, dotted with black. Fabr. Inhabits American islands.

Ciliatus. Thorax ciliated, obtusely spinous, and black; margin and band behind yellow; posterior thighs serrated. Fabr. An American species.

Melacanthus. Thorax acutely spinous; dusky ferruginous; spines black; abdomen black with yellowish stripes. Fabr. Inhabits Africa.

Aggressor. Thorax acutely spinous; tail four toothed; body yellowish; spines same colour. A new Holland species, described from the Banksian cabinet. Fabr.

Vittatus. Thorax somewhat spinous; greenish; wing-cases with a yellow stripe near the margin. Fab. Inhabits the Cape of Good Hope.

Hamatus. Thorax acutely spined; green; abdomen serrated, the denticles black. Fabr. An East Indian species.

Velox. Thorax acutely spined, with two dots; wing-cases with a yellow dot at the base, and streak at the tip yellow. Fabr. Inhabits America.

Humeralis. Green; wing-cases yellow at the base. Thunberg. Country unknown.

Comma. Cinereous; scutel with a yellow line. Thunb. Inhabits Africa.

Transversus. Green; head and anterior part of the thorax yellow. Thunb. Same country as the former.

Fullo. Black, specked with white; head and thorax with a white line. Thunb. Inhabits Japan.

Tibialis. Chesnut-brown, with white and brown lines; scutel with two white spots. Thunb. Country unknown.

* *Ovate; thorax unarmed.*

Aurantius. Orange; head, anterior margin of the thorax, marginal spots on the abdomen, and legs black. Fabr. Donov. Inf. China. Inhabits China and other parts of India.

Punctatum. Above blackish; thorax behind orange; wing-cases white with a black dot. Fabr. *Cimex nigripes*, Sulz. Inhabits Java.

Nigripes. Above sanguineous; scutel with two spots and wing-cases with one spot of black. Fabr. *Cimex incarnatus*, Drury. An East Indian insect.

Iserti. Testaceous; head, thorax behind, scutel anteriorily, band on the wing-cases, with the wings and legs, blue. Fabr. According to Dr. Isert, inhabits the woods of Guinea.

Papillosus. Olive; antennæ black; sternum gibbous, and compressed. Fabr. *Cimex Chinensis*, Thunberg. Described perhaps erroneously as a native of Sierra Leone, Africa. We have received the species from China. Donov. Inf. China and India.

Rubens. Red; head, anterior part of the thorax and scutel greenish; margin of the abdomen spotted with yellow. Fabr. An East Indian species.

Danus. Sanguineous; head, scutel at the base, and wings, black. Fabr. *Cimex danus*, Stoll. *Cimex afer*, Drury. Inhabits American islands.

Obscurus. Fuscous; thorax, wing-cases, and scutel dusky olive; last joint of the antennæ yellow. Fabr. Inhabits the East Indies.

Torquatus. Green; head, and anterior part of the thorax, yellowish. Fabr. A native of Italy.

Ritulans. Green and brassy; a sanguineous band on the anterior part of the thorax; fore part of the scutel and wing-cases yellowish. Fabr. An African species.

Guttatus. Brassy green, with whitish dots; anterior shanks dilated and membranaceous. Fabr. A native of Siam. Banksian cabinet.

Viridulus. Above yellow, dotted with green; beneath green. Linn. A native of India.

Prasinus. Green, and without spots; last joints of the antennæ rufous with the tip fuscous. Linn. Found in woods in Europe; in England rarely. Donov. Brit. Inf.

Dissimilis. Above green, beneath ferruginous. Fabr. A native of Germany.

Juniperinus. Green; margin entirely and tip of the scutel yellow. Fabr. Found on the juniper in Europe.

Smaragdulus. Green, scutel with three yellow spots at the base. Inhabits Madeira.

Azureus. Dusky-green; mouth and legs yellowish. Fabr. A native of Guinea.

Beryllus. Pale; margin of the thorax orange; wing-cases with a ferruginous spot, and marginal little lines of black. Fabr. An East Indian insect.

Calidus. Above fuscous, beneath testaceous; antennæ black. Fabr. Inhabits Sierra Leone. Dr. Pflug.

Lynx. Greenish; margin of the abdomen with black ocellar spots. Fabr. A native of Hungary.

Cœlebs. Greyish-brown; three dots on the scutel with the tip yellowish. Inhabits New Holland. Described by Fabricius from a specimen in the Banksian cabinet.

Iratus. Green-brown, thorax with a yellow band. Fabr. Inhabits Cayenne.

Dumosus. Dusky; dorsal line, two dots on the scutel, and ring on the shanks rufous. Linn. Inhabits the North of Europe.

Tripunctatus. Yellowish; three lines on the head, and three dots on the scutel black. Fabr. An American species.

Atomarius. Grey and fuscous varied; wings white, dotted with fuscous. Fabr. Inhabits America.

Nubilis. Grey and black varied; wings white, striated with black. Fabr. A native of the Cape of Good Hope. Banksian cabinet.

Tristriatus. Yellowish; wing-cases with an ocellar black spot at the tip; abdomen with three white lines. Fabr. An Italian insect. Dr. Allioni.

6-Punctatus. Pale yellow and black varied; thorax pale yellow, with six black dots. Linn. An Indian species.

Signatus. Grey; scutel with a black stripe. Fabr. A native of Sierra Leone.

Gravis. Fuscous; scutel with two yellow dots; wing-cases with a black dot. Fabr. A native of New Zealand.

Meditabundus. Above green; wing-cases fuscous, beneath yellowish. Fabr. A South American species. Dr. Isert.

Cinctus. Green; margin of the thorax and abdomen sanguineous. Fabr. *Cimex Forskahlii*, Gmel. Inhabits the East.

Rubrofasciatus. Greenish; thorax with a sanguineous band. Fabr. Inhabits Tranquebar, and is described from a specimen in the cabinet of Hybner. Gmelin alters the Fabrician specific name to Hybneri.

Agathinus. Punctured yellowish; scutel with a black band; abdomen above black; tail rosy. Fabr. A German species.

Lituratus. Green speckled with brown; thorax with a band; wing-cases with a blotch of sanguineous. Fabr. Inhabits Italy.

Cruentus. Green; thorax, margin of the abdomen, with the antennæ and legs ferruginous. Fabr. A native of Surinam.

Geniculatus. Dusky; thorax and margin of the abdomen yellowish; tail and joints of the legs ferruginous. Fabr. Inhabits Cayenne.

Mixtus. Punctured, grey, spotted with black; margin of the abdomen black, with yellow dots. Fabr. Same country as the former.

Picus. Grey; antennæ and shanks of the legs black, with white rings. Fabr. An Indian species.

Griseus. Grey; sides of the abdomen varied with black and white; sternum projecting. Linn. Found in gardens in Europe.

Interstinctus. Grey; margin of the abdomen with black spots. Linn. Inhabits Europe.

Funebris. Ovate, black, antennæ, legs, and wings same colour. Fabr. Inhabits Sierra Leone.

Baccarum. Somewhat fulvous; margin of the abdomen spotted with fuscous. Linn. An European insect.

Mucoreus. Black, speckled with white; head black; margin and line in the middle white. Fabr. Inhabits China.

Ornatus. Black and red varied; head and wings black. Linn. Inhabits Europe.

Festivus. Black and red varied; thorax with six black dots; wings fuscous, margin whitish. Linn. *Cimex dominulus*, Scop. Found in the south of Europe.

Cruciatus. Black and pale varied; scutel black with a white cross. Fabr. Inhabits the East Indies.

Bioculatus. Above black; thorax rufous with two black dots; margin of the scutel rufous. Fabr. An American insect.

Gramineus. Roundish, green, and without spots. Fabr. A native of Tranquebar.

2-Punctatus. Dusky rufous; two dots on the scutel, and tip white; margin of the abdomen dotted with black. Fabr. A native of Italy. Called by Gmel. C. *Italicus*.

Bicolor. Black; wing-cases white and black varied; wings white. Linn. Found in gardens in Europe. An English species. Donov. Brit. Inf.

Oleraceus. Blue-brassy; small line on the thorax, tip of the scutel, and dot on the wing-case white or red. Linn. Geoffr. &c. Found in gardens in Europe.

2-Guttatus. Black, with the whole margin white; wing-cases with white dots. Linn. Inhabits Europe; lives chiefly in gardens.

Histrio. Variegated; head and abdomen black with white lines. Fabr. Inhabits Tranquebar. Hybner.

Cæruleus. Blue and without spots. Linn. An European species.

Albo-Marginellus. Blue; margin of the thorax, wing cases, and tip of the scutel white. Fabr. Inhabits Germany. *Cimex albo-marginatus*, Geoffr.

Nigrita. Black; wings white; legs rufous; shanks serrated. Fabr. Inhabits Germany.

Flavicornis. Black; wings white; antennæ yellow; thorax and shanks ciliated. Fabr. Inhabits Europe.

Morio. Deep black; feet rufous. Linn. &c. Found on plants in Europe.

Tristis. Deep black; shield orbicular; thorax retuse. Fabr. *Cimex spinipes*, Schranck.

Spinipes. Black; legs pitchy; shanks very spinous. Fabr. An African species.

Æthiops. Black; thorax with an impressed line in the middle; shanks very spinous and black. Fabr. Inhabits Cayenne. Rohr.

Lugens. Fuscous; thorax, small line on the scutel and margin of the abdomen white. Fabr. A native of America.

Melanocephalus. Grey; head and base of the scutel brassy black. Fabr. A native of England.

Perlatus. Grey; head black; scutel with a white dot each side. Fabr. Inhabits Germany. Smidt.

Decrepitus. Black; head and legs fuscous. Fabr. Found on grass in Denmark.

Acuminatus. Front attenuated, whitish with fuscous streaks; tip of the antennæ rufous. Lin.

Elegans. Dark green; thorax yellow with four blackish spots; margin of the scutel and transverse band yellow.

low. Donov. Inf. New Holland. A recently difcovered fpecies.

Genus *Coreus*, Fabr. *Cimex*, Linn.

Marginatus. Thorax obtufe fpinous; margin of the abdomen acute; antennæ in the middle rufous. Fabr. *Cimex marginatus*, Linn.

Scapa. Thorax obtufely fpined; margin of the abdomen acute, and fpotted with white; two fpines on the anterior part of the head. Fabr. Inhabits Germany.

Spiniger. Thorax obtufely fpinous, and dentated; head with four fpines. Fabr. Inhabits Italy.

Venator. Thorax obtufely fpinous, dufky grey; beneath yellowifh; antennæ and legs ferruginous. Fabr. An Italian fpecies. Dr. Allioni.

Bellator. Thorax fpinous, above fufcous; beneath yellowifh; antennæ black with white rings. Fabr. A native of Cayenne.

Armiger. Thorax acutely fpinous, grey; fcutel with two dots; antennæ and legs pale. Fabr. An African fpecies in the Bankfian cabinet.

Lanciger. Thorax acutely fpined, yellowifh; thorax behind, and wing-cafes fufcous; wing-cafes with a white band. Fabr. Inhabits Guinea. Dr. Ifert.

Hastator. Thorax acutely fpined, dufky grey; margin of the abdomen whitifh with black dots. Fabr. Inhabits fame country as the laft.

Scorbuticus. Thorax obtufely fpinous, fufcous; pofterior legs dotted with black. Fabr. Found in the iflands of America.

2-Guttatus. Thorax acutely fpined, grey, with two callous white dots on the fcutel. Fabr. Inhabits the Eaft Indies.

Delirator. Thorax acutely fpined, yellowifh, dotted with black; pofterior part of the thorax and the wing-cafes fufcous.

Defensor. Thorax acutely fpined; tail four-toothed; body green; fpines black. Fabr. A native of New Holland. Bankfian cabinet.

Pugnator. Thorax acutely fpined, oblong; above fufcous, beneath yellowifh; antennæ rufous with the tip black. Fabr. Inhabits Tranquebar. Hybner.

Fasciculatus. Thorax fomewhat fpinous cinereous; wings fufcous; legs with fafciculated hairy tubercles. Fabr. Inhabits the Cape of Good Hope.

Insidiator. Thorax acutely fpinous; above rufous, beneath yellowifh. Fabr. Inhabits Barbary.

Calumniator. Thorax acutely fpinous, cinereous-brown; beneath yellowifh with ftreaks of black dots. Fabr. A native of India. Prof. Abildgaard.

Hirticornis. Thorax acutely fpinous, ferrated, and rufous; antennæ hairy; pofterior thighs ferrated. Fabr. Inhabits Barbary.

Sulcicornis. Thorax obtufely fpinous; above rufous, beneath yellowifh; antennæ triangular, abdomen fomewhat fquare. Fabr. A native of Barbary. Muf. Desfontaines.

Rhombeus. Thorax acutely fpined; abdomen dilated, rhombic, and armed behind with fix teeth. Linn. *Coreus rhombea*, Fabr. An African infect.

Quadratus. Thorax obtufely fpinous; above fufcous, beneath yellowifh; abdomen fquare. Fabr. A native of Germany.

Hastatus. Thorax acutely fpinous, and dentated; wing-cafes dufky with a pofterior white ftreak. Fabr. Inhabits Tranquebar. Hybner.

Gravidator. Thorax ferrated, dufky cinereous; margin of the wing-cafes dotted with black; wings white; antennæ fufcous. Fabr. Inhabits South American iflands.

Genus *Lygæus*, Fabr. *Cimex*, Linn.

* *Thorax fpinous.*

Valgus. Thorax fpinous and ferrated; pofterior thighs incurvated, and with the fhanks armed with a fingle tooth. Linn. Inhabits the Cape of Good Hope.

Serratus. Head, thorax and abdomen ciliated with fpines; body black. Fabr. Inhabits America.

Merianæ. Thorax fomewhat fpinous; wing-cafes fufcous, reticulated with white; abdomen fpinous at the bafe. Fabr. A native of Surinam.

Grossipes. Thorax ferrated, lineated with red; pofterior thighs thick, and with the abdomen at the bafe fcabrous; fhanks with a fingle tooth. Fabr. Inhabits Tranquebar.

Tragus. Spines of the thorax compreffed, lunulated, and ferrated; pofterior fhanks membranaceous and ferrated. Fabr. A native of China. Dr. Pflug.

Tenebrosus. Thorax fomewhat fpinous; pofterior thighs incurvated, and clubbed; bafe of the abdomen with three fpines. Fabr. &c. An Eaft Indian fpecies.

Fulvicornis. Thorax fpinous, and ferrated; brown; thighs bidentated; pofterior one with many teeth. Fabr. An Eaft Indian fpecies.

Incubator. Thorax obtufely fpined, and ferrated; fnowy before the margin; body grey. Fabr. Inhabits Carolina.

Heros. Thorax obtufely fpined, and ferrated; fufcous; pofterior thighs clavated and dentated; fhanks membranaceous and ferrated. Fabr. Inhabits the Eaft Indies.

Femoratus. Thorax flightly fpined; pofterior thighs incurved, and dentated; pofterior fhanks compreffed. Fabr. Inhabits India. Bankfian cabinet.

Curvipes. Thorax acutely fpined; thighs bidentated at the tip; pofterior ones incurved. Fabr. Inhabits Africa.

Clavipes. Thorax ferrated, dufky; thighs with many fpines; pofterior ones thick. Fabr. A native of China.

Dentator. Thorax ferrated, dufky; pofterior thighs dentated; fhanks pale. Fabr. A native of Italy. Dr. Allioni.

Pictor. Thorax fpinous, and ferrated; ochraceous; wing-cafes fpeckled with black. Fabr. A native of the Eaft Indies.

Compressicornis. Thorax fpinous and ferrated, with ocellar black fpots; body black; laft joint of the antennæ compreffed and white at the bafe. Fabr. A native of St. Jago.

Membranaceus. Thorax fpinous and without fpots, blackifh; wing-cafes with a whitifh band; pofterior fhanks membranaceous and dentated. Fabr. Inhabits South America.

Auctus. Thorax fomewhat fpinous and black; two fpots fulvous; wing-cafes with a yellow band; pofterior fhanks membranaceous and yellow. Fabr. A native of America.

Sanctus. Thorax acutely fpined, oblong, rufous; wing-cafes black, with a ferruginous crofs. Fabr. A Brafilian infect.

Lætus. Thorax fpinous, green; head, band on the wing-cafes, abdomen, and thighs, yellow; wing-cafes black. Fabr. Inhabits Cayenne.

Kermesinus. Thorax fomewhat fpinous, oblong, rufous, with a whitifh band, dotted with black; pofterior thighs with many teeth. Linn. A native of Surinam.

Australis. Thorax fomewhat fpinous, oblong, black; a red band on the thorax before; pofterior fhanks membranaceous. Fabr. Defcribed from a fpecimen taken in Otaheite. Bankfian cabinet.

Balteatus.

Balteatus. Thorax somewhat spinous; ferruginous; wing-cases with a transverse yellow line; posterior thighs with many teeth. *Cimex balteatus*, Drury. Inhabits South America.

Sinuatus. Thorax acutely spined, livid; posterior shanks compressed, sinuated and black. Fabr. A native of Cayenne.

Serripes. Thorax acutely spined, rufous; posterior thighs dentated. Fabr. A native of New Holland.

Dentipes. Thorax spinous, elongated; posterior thighs long and serrated; body fuscous beneath; sides white. Fabr. Inhabits Africa.

Linearis. Thorax acutely spined, elongated, fuscous; posterior thighs lengthened, and dentated. Fabr. A native of China. Drury.

Crenulatus. Thorax dentated and rufous, with a black spot; posterior thighs dentated; body black. Fabr. Inhabits American islands.

4 Spinosus. Elongated, red; thorax armed with four spines. Linn. A native of America.

* *Thorax unarmed.*

Phasianus. Fuscous; posterior thighs arched, clavated, and armed with a single tooth; abdomen at the base beneath gibbous. Fabr. An African insect.

Bellicosus. Fuscous; posterior thighs arched and dentated; abdomen four-spined. Fabr. An African species. Banksian cabinet.

Meleagris. Fuscous; extreme joint of the antennæ, and anterior shanks yellow; all the thighs serrated. Fabr. A native of China.

Gallus. Wing-cases fuscous with yellow streaks; disk of the abdomen rufous; posterior thighs serrated. Fabr. Inhabits Surinam.

Faber. Black; abdomen fuscous, with yellow margin; anterior thighs bidentated at the tip. Fabr. A native of Paulicondor.

Indus. Abdomen red, and bidentated; wing-cases fuscous with pale streaks. Linn. A native of Cayenne.

Civilis. Red and black varied; thorax with two red lunules; wings fuscous, spotted with white. Fabr. Inhabits Tranquebar.

Saxatilis. Black; thorax with the lateral margins and line down the middle red; wing cases with three red spots; wings immaculate. Fabr. Inhabits the south of Europe.

Hyosagami. Black and red varied; wings fuscous and without spots. Linn. An European species.

Varicolor. Black and red varied; wing-cases black; with two yellowish spots. Fabr. Found in Trinity island.

Scabrosus. Black; margin of the thorax and two bands on the upper wings reddish. Fabr. A native of America.

Leucurus. Black; wing-cases red; wings black, the base and tip white. Fabr. Inhabits Amsterdam island.

Koenigii. Testaceous; wing-cases with a black dot; wings deep black. Fabr. Inhabits Tranquebar.

Slanbuschii. Sanguineous; thorax with an abbreviated band; scutel, dot on the wing-cases, and the wings black. Fabr. Inhabits China. Donov. Inf. China.

Ægyptius. Red and black varied; wing-cases red, with a black dot. Linn. A native of Egypt.

4-Guttatus. Wing-cases rufous, with black band; wings with two white dots. Fabr.

Punctato Guttatus. Black; wing-cases rufous, with a middle black dot; wing black with two white dots. Fabr.

Suturalis. Rufous; antennæ and wings black; the suture entirely white. Fabr.

Rolandri. Black; wings with a rhombic yellow spot. Linn. Found on the pine in Europe.

Sordidus. Black; thorax behind, wing-cases and legs grey. Fabr. Inhabits Tranquebar.

Genus *Miris*, Fabr. *Cimex*, Linn.

Dolabratus. Wing-cases ferruginous, whitish at the sides; antennæ black. Linn. A native of Europe.

Lævigatus. Whitish; sides white. Degeer. A native of Europe.

Lateralis. Black; sides whitish. Fabr. An European species.

Holsatus. Whitish; two lines on the thorax brown, and wing-cases brown within. Fabr. Inhabits Europe.

Pabulinus. Green, without spots; wings hyaline. Linn. Inhabits Europe.

Virens. Green; ends of the feet, and tips of the antennæ rufous. Fabr. An European species.

Pallens. Pale; head and body black. Paykull. A native of Sweden.

Calens. Head, thorax, and wing-cases black; scutel fulvous. Linn. A native of India.

Gronovii. Thorax and wing-cases black, with a yellow line forming a band. Linn. Inhabits India.

Ferus. Grey and without spots. Linn. Found in European woods.

Vagans. Grey; head and line on the thorax black; legs testaceous. Fabr. A native of Sweden.

Cingulatus. Fuscous; head, and three lines on the thorax, with the margin of the wing-cases white. Fabr. A native of India.

Marginellus. Black; three lines on the thorax white; wing-cases edged with white, and at the tip a scarlet spot. Fabr. An Italian insect.

Striatus. Black; wing-cases yellow striated with brown; tip and legs rufous. Linn. Inhabits Europe.

Abietis. Fulvous spotted; legs rufous; thighs thick and dentated. Degeer. Inhabits Europe.

Ulmi. Above rust colour; wing-cases streaked with sanguineous; wings varied behind with brown and white. Fabr. Linn. &c. Found on the elm in Europe.

Genus *Gerris*, Fabr. *Cimex*, Linn.

Lacustris. Black; anterior legs very short. Linn. Very common in ditches during summer. Donov. Brit. Inf.

Paludum. Black; beneath silvery; margin of the abdomen somewhat ferruginous. Fabr. Twice the size of the last. A native of Europe.

Fossarum. Above fuscous; margin, thorax, scutel, and dorsal line yellow. Fabr. A native of the East Indies.

Stagnorum. Nearly round; blackish; thorax with two globular dots in the middle. Linn. Inhabits England.

Rivulorum. Black, dotted with white; abdomen fulvous. Fabr. Inhabits the mountainous rivulets of Alsace.

Pallipes. Black; legs pale; breast two-spined. Fabr. An Italian insect. Cabinet of Dr. Allioni.

Culiciformis. Thorax armed with many spines; grey; wing-cases with many blotches. Fabr. An American species.

Mantis. Fuscous; streak on the wing-cases and joints of the legs white. Fabr. Country unknown.

Tipuliformis. Sanguineous; wings and legs black; antennæ very long. Fabr. A native of Guinea.

Præcatorius. Brown; head and thorax two-spined; margin

margin of the thorax elevated behind and obtufe ; antennæ very long. Fabr. A native of Guinea. Dr. Ifert.

Pedestris. Body fufcous and yellow varied; pofterior thighs elongated and toothed. Fabr. Inhabits the Eaft Indies.

Filiformis. Antennæ ferruginous; body linear, pale, and greenifh. Fabr. A native of America.

Oratorius. Greenifh; antennæ before the tip white. Fabr. A native of India.

Angustatus. Above grey, beneath yellowifh; antennæ and legs fomewhat teftaceous. Fabr. A native of China. Dr. Pfiug.

Filum. Fufcous; wings abbreviated; legs very long. Fabr. An Eaft Indian fpecies in the cabinet of the late Dr. Fothergill.

Longipes. Black; margin of the thorax and band on the wing-cafes fanguineous. Fabr. An American fpecies.

Cursitans. Above fufcous, beneath cinereous; legs very long; tail bidentated. Fabr. A New Holland infect. Bankfian cabinet.

Tipularius. Whitifh; all the legs long; thighs clavated; antennæ biclavated. Fabr.

Vagabundus. Wing-cafes with the wings fufcous and white varied; legs very long, ringed with cinereous. Fabr. An European infect.

Clavipes. Cinereous; thighs clavated, antennæ biclavated. Fabr. Inhabits Sweden.

Apterus. Apterous, fufcous; abdomen fulvous; fpot at the bafe black with white dots. Fabr. An Italian infect.

Currens. Apterous, fufcous; margin of the abdomen raifed, fulvous with black dots. Fabr. A native of Italy.

Genus *Reduvius*, Fabr. *Cimex*, Linn.

Gigas, Black; margin of the thorax and obfolete flexuous band on the wing-cafes rufous. Fabr. Inhabits the Eaft Indies.

Personatus. Antennæ capillary at the tip; body beneath fubvillous and fufcous. Linn.

Villosus. Villous, black; fcutel at the tip recurved and pointed. Fabr. A native of Barbary.

Barbicornis. Black; thorax and bafe of the abdomen olive. Fabr. Inhabits Sierra Leone.

Maculatus. Rufous; thorax with four; wing-cafes with three black fpots. Fabr. An African fpecies.

Stridulus. Glabrous, black; wing-cafes rufous; thin margin cinereous, and dotted with black. Fabr. Inhabits Europe.

Nitidulus. Black; thorax olive; anterior thighs rufous. Fabr. Inhabits Africa.

Pilipes. Black, thorax and wing-cafes at the tip villous with grey hairs. Fabr. A native of Cayenne.

Longipes. Red; wing-cafes black; bafe and band red. Linn. A native of American iflands.

Phalangium. Rufous; antennæ and legs elongated and black. Fabr. A native of the American iflands.

Nigripennis. Rufous; wing-cafes and abdomen beneath black; fcutel bidentated. Fab. Inhabits the Eaft Indies.

Marginatus. Above rufous, wing-cafes black; abdomen deep black with rufous margin. Fabr. Inhabits the Eaft Indies. Bankfian cabinet.

Rufipes. Deep black; wing-cafes grey veined with black; margin of the abdomen and pofterior legs rufous. Fabr. A native of Cayenne.

2-Pustulatus. Above black; a rufous dot at the tip of the wing-cafes. Fabr. Inhabits Surinam. Bankfian cabinet.

Annulatus. Tip of the antennæ capillary; body black, beneath fpotted with fanguineous. Linn. Geoffr.

Sanguineus. Black; margin of the abdomen fanguineous fpotted with black. Fabr. A native of Barbary.

Bicolor. Deep black; thorax behind, wing-cafes, and margin of the abdomen pale. Fabr. An African fpecies. Bankfian cabinet.

Litura. Dull, fufcous; tip of the antennæ and blotch in the middle of the wing-cafes white. Fabr. A native of Cayenne.

Attelaboides. Teftaceous and black varied; anterior part of the thorax teftaceous, with two black teeth. Fabr. A New Holland infect.

Diadema. Black; head and thorax fpinous. Fabr. A native of North America.

4-Spinosus. Thorax four-fpined, black; wing-cafes teftaceous; head and legs yellow. Fabr. Inhabits Cayenne.

Fasciatus. Head and thorax black; wing-cafes yellowifh; band and wings at the tip black. Fabr. A native of Cayenne.

Maurus. Ferruginous, margin of the abdomen fpotted with black; anterior part of the thorax fomewhat fpinous. Fabr.

Fornicatus. Thorax raifed, vaulted, pale with three brown fpots. Fabr. A native of Cayenne.

Acantharis. Thorax fpinous; abdomen ciliated with fpines. Fabr. Inhabits Jamaica.

Guttula. Gloffy black; wing-cafes and legs fanguineous; wings with a white dot. Fabr. A native of Germany. Dr. Heiffe.

Elongatus. Elongated, rufous; antennæ and legs black. Fabr. Inhabits Africa.

Minutus. Black, fcutel at the tip, and wing-cafes at the bafe white. Fabr. Inhabits Paris.

CIMICIFUGA, in *Botany*, (fo called from its driving away bugs). Linn. gen. 1282. Schreb. 933. Gært. 810. Juff. 234. Clafs and order, *polyandria tetragynia*. Nat. Ord. *Multifiliquæ*, Linn. *Ranunculaceæ*, Juff.

Gen. Ch. *Cal.* four or five-leaved; leaflets roundifh, concave, caducous. *Cor.* Nectaries refembling petals, pitcher-fhaped, membranous. *Stam.* Filaments twenty, projecting a little out of the flower; anthers didymous. *Pift.* Germs four to feven; ftyles recurved: ftigmas adhering longitudinally to the ftyle. *Peric.* Capfules from four to feven, oblong, opening with a lateral future, Linn. (opening at the ventral future, Gært.) *Seeds* many, covered with fpreading fcales.

Eff. Ch. Calyx four or five-leaved. Nectaries four, pitcher-fhaped. Capfules from four to feven.

Sp. C. *fœtida*, Mart. Lam. Willd. Gmel. Sib. 4. tab 70. Lam. Ill. Pl. 487. Gært. tab. 140. (Actæa cimicifuga, Linn. Sp. Pl. Thalictroides fœtidiffimum, Chriftophorianæ facie, Amm. ruth. 102.) *Root* perennial, thick, knotty, fhort, with many thickifh fibres creeping tranfverfely. *Stem* fix feet high, cylindrical, flightly ftriated, a little hairy, hollow, with alternate branches. *Leaves* pinnated; leaflets egg-fhaped, ferrated; terminating one commonly three-lobed. *Flowers* in long alternate terminal racemes, on fhort peduncles. *Capfules* netted, beaked with the fhort curved ftyle, one-celled, opening at the interior or ventral future. *Seeds* feveral, oblong, covered with linear-oblong flexile pale fcales, attached to the future. The whole plant, efpecially in its wild ftate, has an almoft infupportable fmell. According to Linnæus it bears a great refemblance to Actæa racemofa. A native of Siberia, from the river Jenifea, flowering

flowering in the middle of July, and ripening its feed in Auguft. It varies much in the number of parts in the calyx, corolla, and piftils; nor is either the fex or proportion conftant.

CIMIER, the French term in *Heraldry* for a creft. See Crest.

Cimier, in *Military Language*. The ancient knights, or chevaliers, in France and other countries, put each of them a *cimier* on his helmet by way of ornamenting it. But it was fo incommodious, by its weight, that fubfequent chevaliers laid it afide; and contented themfelves with placing fmall allegorical figures in its ftead. See Crest.

CIMINIA, in *Ancient Geography*, a country of Italy, in Etruria.

CIMINIUS *lacus*, a lake of Italy, in Etruria, mentioned by Livy.

Ciminius *Mons*, a mountain of Etruria, fituated N. and N.E. of the lake of the fame name.

CIMKOWICZKE, in *Geography*, a town of Lithuania, in the palatinate of Novogodrek, 18 miles W. of Sluck.

CIMMERII, in *Ancient Geography*, the name of a people, who, according to Pofidonius, were the fame with the Cimbri. The firft appellation, by which they were diftinguifhed, is unknown; but it appears that they did not acquire the fecond before they inhabited the town of "Cimmerium," built in Afia upon the bank of the ftrait that feparates it from the Tauride. The time of the eftablifhment of the Cimmerians muft have been very ancient; for it appears they had gained celebrity in the 9th century before the Chriftian æra, becaufe Homer mentions them in his "Odyffey" as a people who inhabited the northern and north-weftern parts of Greece, in a climate approaching the pole. Strabo fuggefts (l. iii.) that from the time of Homer, the Cimmerians and Amazons entered into Afia Minor, and penetrated into Æolia and Ionia; and Eufebius, in his Chronicle, marks, in the year 1076 before Chrift, an incurfion of the Cimmerians and Amazons into Afia Minor. Orofius alfo mentions another about the year 782, thirty years before the foundation of Rome. The Cimmerians, according to Pofidonius, advanced gradually from the fea-coaft to the interior of Germany, and at length occupied the whole country, which extended from the ocean to the Euxine fea. The principal eftablifhment of the Cimmerians was towards the banks of the Tyras, according to Herodotus (l. iv. c. 12.) who fays, that they there affembled to hold a general council of the nation, on the fubject of the Scythian invafion. Having advanced towards the eaft, they had traverfed the Boryfthenes and the Hypanis, and had paffed the Cherfonefus or peninfula, which has always preferved their name. From this country they proceeded to the Bofphorus, or the ftrait which feparates it from Afia, and by which the waters of the Tanais, after having formed the Palus-Mæotide, difcharge themfelves into the Euxine fea.

The country bordering on the Palus Mæotis, and the Bofphorus, which was inhabited by the Cimmerii, is reprefented by the ancients as an inhofpitable place, covered with forefts and fogs, which the fun could not penetrate (See Bosphorus); and their frightful defcription of it gave Cicero and Ovid occafion to fay, that an eternal night reigned in this gloomy climate, and that fleep had taken up its abode here. Hence "Cimmerian darknefs" became, according to Lactantius, proverbial, fignifying an impenetrable darknefs, and likewife a gloomy and ftupid mind.

Herodotus adds, that they took poffeffion of the two banks of this ftrait, and there conftructed forts, the veftiges of which remained in his time. Strabo, fpeaking (l. xi.) of Cimmerium, fays, that it was built on the Afiatic bank of this ftrait. Herodotus fays, moreover, that the Cimmerians, after having croffed the ftrait, proceeded along the fea-coaft, and advanced into Afia Minor, which they ravaged, whilft the Scythians were pillaging Media and Paleftine. He adds, that the Cimmerians penetrated into the peninfula of Sinope, which they found to be a defert. We have an account, fince the year 1076, of two expeditions of the Cimmerians into Afia Minor. In one of thefe, it is faid, on the authority of Ariftotle, they feized poffeffion of the town of Antandros, fituated at the foot of Mount Ida, at the bottom of the gulf of Adramyttium. He adds, that thefe people gave the name of "Cimmeris" to this town, and that they continued mafters of it for a century. In thefe two invafions, the Cimmerians pillaged the town of Sardes. Strabo fays (l. i.) that Midas, king of Phrygia Major, having been conquered by the Cimmerians, killed himfelf, in order to avoid falling into their hands. Eufebius places the death of Midas at the year 697, or about the 4th year of Gyges. Strabo farther informs us (l. xiv.) that the Cimmerians remained mafters of the plains of Caifter or of Lydia, for a confiderable time after the deftruction of Magnefia, and the pillage of Sardes. However, he fometimes diftinguifhes the people who deftroyed Magnefia and pillaged Sardes, fometimes by the name of Cimmerians, and fometimes by that of Treres, or Trerones, and calls their chief Lygdamis; and this, according to Callimachus, was the name of the king of the Cimmerians, who came from Scythia, or the coaft of the Euxine fea, to ravage the plains of Caifter. Hefychius alfo informs us, that this Lygdamis pillaged the town and burnt the temple of Ephefus. Strabo (l. xiv.) fays, that this Lygdamis, after having ravaged Lydia and Ionia, loft his life in Cilicia; that is unqueftionably the Cilicia of the Troade, where the Cimmerians had their place of arms (Id. l. i.). This author always gives the furname of Cimmerians to the Treres or Trerones of Afia, in order to diftinguifh them from thofe of Thrace. Herodotus fays, that after the council held on the banks of the Tyras, already mentioned, the Cimmerians, conceiving themfelves unable to refift the Scythians, migrated towards the eaft; and that the Scythians, having taken poffeffion of their country, difpatched an army to purfue them, but that this army having loft its way in the mountains, wandered, in croffing the Caucafus, and followed the courfe of a valley, which led them to the coaft of the Cafpian fea. The Cimmerians, at length, proceeded along the coaft of the Euxine, and returned to the Colchide in Afia Minor.

The Cimmerian nation confifted, at the time of the Scythian invafion, of three divifions; viz. thofe of Afia Minor, the colony of the Cherfonefus, and the principal body of the nation, which inhabited the regions fituated between the Danube and the Boryfthenes, the moft confiderable eftablifhments of which were formed on the bank of the river Tyras. The Cimmerians of Afia Minor, accuftomed to plunder, were attacked by Alyattes, a valiant and active prince, who deftroyed moft of them that remained, and thofe who efcaped the fword of the conquerors were made flaves, and difperfed through the countries of Lydia and Myfia. The Cimmerians of the Cherfonefus and the Bofphorus poffeffed cities on both fides of this ftrait; but they found it difficult to defend themfelves againft the Scythians. They probably, therefore, abandoned the plains of the ifthmus and Bofphorus, and retired into the mountains to the fouth and eaft of the peninfula; mountains that were fertile, and yet difficult of accefs to the cavalry of the Scythians. As to the principal body of the Cimmerians, who inhabited the country between the Danube and the Boryfthenes, the Scythians continued mafters of their country

500 years before Christ. The Greeks had many colonies on the sea-coast, and these colonies extended their commerce into the interior parts of the country. It is from the inhabitants of these colonies, and from a Scythian prince, that Herodotus derived his information concerning these territories. It is probable that the Cimmerians ascended the Carpathian mountains, and descended on the western side of it. After their flight, when this event took place, the different people which composed the Cimmerian league, separated from one another, and settled in different places; and as the league no longer subsisted, each people resumed its ancient name, and began to form a distinct state.

The learned M. Pezron, in his "Antiquities of Nations," &c. maintains, that the Cimmerians were of the same family with the *Sacæ;* and that whilst these were proceeding from Bactriana, which they had previously occupied, by the south, the Cimmerians, who likewise came from the same country, took their route by the north of Asia; and he represents them as making their way by force of arms, till they settled upon the Palus Mæotis. In proof of the opinion which he advances, he appeals to Plutarch, Posidonius, Diodorus, and Strabo. Herodotus, however, to whom we have already referred, assigns to their march a quite contrary direction, from the Palus Mæotis towards Caucasus and the east (l. iv. c. 12.) The writers above cited, says Mr. Bryant (Anal. Anc. Mythol. vol. iii.), have not a syllable to the purpose for which M. Pezron alleges their authority. That there were such people as the Cimmerians upon the Mæotis, is, indeed, as certain as that there were Phrygians in Troas, and Spartans at Lacedæmon. But that they came from Bactria, and fought their way through different countries; that they were the brethren of the Scythians, styled Sacæ, and took the upper route, when the others were making their inroad below, are circumstances which, says Mr. Bryant, have not the least shadow of evidence. They are not mentioned by the authors to whom M. Pezron appeals, nor by any writers whatever. Indeed Strabo expressly says (l. xi.), that the Cimmerians were driven out of their country by the Scythians.

CIMMERII, a people of Italy, who inhabited the environs of Baiæ and Cumæ near the lake *Avernus*, which see. Those that have given an account of this colony, among whom are Lycophron, Pliny, Eustathius, Servius, &c. inform us, that the sun never shines in this small canton; but Strabo, who was better acquainted with these countries, describes them as abounding with all the necessaries of life, and rather pleasant than disagreeable.

CIMMERIUM, a town of Asiatic Scythia, or the Cimmerian Bosphorus. It was the last city to the right, when a person passes this straight from the south or the north.

CIMMERIUM, *Eski-krim*, a town in the interior of the Tauric Chersonesus, according to Ptolemy and Strabo. M. le Peyssonel, in his Observations historical and geographical, says, that this town, now reduced to a wretched burgh, was formerly large and flourishing; as appears from several existing monuments. It was situated to the north of Mount Cimmerius, and to the W.N.W. of Theodosia.—Also, a town of Italy, in Campania, situated, according to Pliny, near the Lucrine and Avernian lakes.

CIMMERIUM *Promontorium*, a promontory of Asia, on the southern coast of the Palus Mæotis, marked by Ptolemy between the town of Apatura and the mouth of the river Vardan.

CIMMERIUS BOSPHORUS. See BOSPHORUS.

CIMMERIUS *Mons, Aghirmiche-Daghi*, a mountain in the Tauric Chersonesus, according to Strabo, who says, that it derived its name from the Cimmerii, a people who anciently occupied the whole Bosphorus. See CIMMERII, *supra*.

CIMOLIA, a place of Greece in the Peloponnesus. Diodorus Siculus reports that the Athenians gained in this place a victory over the inhabitants of Megara.

CIMOLIA, in *Mineralogy*. This term occurs in some of the ancient pharmacopœias as designating pipe-clay and fuller's earth, of which the former was denominated cimolia alba, and the latter cimolia purpurascens. See PIPE CLAY and FULLER'S EARTH.

CIMOLIA *Terra*. See CIMOLITE.

CIMOLIS, or CIMOLUS, in *Ancient Geography*, one of the Cyclades, or islands of the Archipelago. It was also called *Echinussa*, or Viper Island, on account of the great number of those reptiles with which it abounded, at a time, when little frequented by men, it was covered only by rocks, forests, and brambles. It was anciently known by the substance which was found in it, and to which it gave the name of "Cimolia Terra." It was situated a little to the N.E. of Melos, and to the S.S.W. of Siphnos. The Greeks at this day call it "Kimoli;" but it is more generally known by the name of "Argentiera," which see. The virtues of the earth which it produces are recited by Pliny (N. H. l. xxxv. c. 17.), Dioscorides (l. v. c. 133.), and Galen (Epitome de Curatione Morborum). See CIMOLITE.

CIMOLIS, an episcopal town of Asia Minor in Paphlagonia.

CIMOLITE of Klaproth, *Cimolia* of Pliny, in *Mineralogy*, is a mineral of a light, greyish, white colour, inclining to pearl-grey; but by exposure to the air it acquires a reddish tint. It occurs in mass, forming large strata; its fracture is earthy, uneven, and its texture more or less slaty. It is opake, of a greasy texture, and may be scraped with a knife like steatite. It adheres firmly to the tongue, stains the fingers in some degree, and though soft, is very tough, and difficultly pulverizable. Sp. gr. 2.

When exposed by itself to the action of the blow-pipe, it becomes at first of a dark grey colour, but afterwards recovers its whiteness with little or no alteration: with microcosmic salt it runs into a colourless globule; with borax it forms a light-brown glass. Its component parts are

63	Silex
23	Alumine
1.25	Oxyd of iron
12	Water
99.25	

It abounds in the island of Cimolis (whence its name), now called Argentiera, and was highly valued by the Greeks and Romans for its detergent properties: at present its use is almost entirely confined to the inhabitants of that island. When triturated with a little water it forms a soft, pap-like mass, and being applied in this state to silk or woollen cloth, and allowed to dry on, it absorbs all the grease which they may contain, like Fuller's earth, but more effectually, and is again discharged by a slight washing, leaving the cloth restored to its original lustre.

CIMON, in *Biography*, an Athenian, son of Miltiades, by Hegisipyle, the daughter of a Thracian king. He served under his father in his youth, and was more addicted to active pursuits, than to those studies and accomplishments, for which the Athenians peculiarly valued themselves. As he advanced in life he showed that he was not deficient in abilities; he possessed a natural eloquence, which, united to an openness and generosity of temper, rendered him well qualified to make his way in a popular government. When his father died he was imprisoned, because unable to pay the fine imposed upon him. He was released from confinement chiefly

chiefly by means of his fister Elpinice, who regarded him with the tendereft affection. Cimon paffed fome of his younger days in licentious pleafures; but at the time of the Perfian invafion, his martial fpirit, and refolute temper fhone forth with great luftre. At the advice of Themiftocles, he quitted the city, embarked on board the fleet, and greatly diftinguifhed himfelf in the naval combat of Salamis. Ariftides having formed a favourable opinion of his integrity and talents, initiated him in public bufinefs, with a view of bringing him forward to counterbalance the influence of Themiftocles. After the expulfion of the Perfians, Cimon was made admiral of the Athenian fleet, which was commanded by Paufanias. In this fituation, his difpofition being a perfect contraft to that of Paufanias, he gained univerfal refpect and efteem, fo that after the commander was recalled, the confederates readily accompanied him in an expedition to Thrace. In this, among many other brilliant and important achievements, he reduced the ifland of Scyros, inhabited by pirates, and returned to Athens with the bones of Thefeus, to be interred in the native city of the hero, which he had quitted four hundred years before. Having re-inforced his fleet, he proceeded to the coaft of Caria, thence to Cyprus, where he was informed that the Perfian fleet lay at anchor. He purfued it to the mouth of the Eurymedon, and there completely defeated it, deftroying many veffels and capturing two hundred. Then landing his men on the fame day, he gained a fignal victory over the land forces of the enemy. This action, which is fo celebrated in ancient hiftory, took place B. C. 470. Cimon afterwards got poffeffion of eighty Phœnician fhips in the port of Cyprus, and he brought back to Athens an immenfe booty, which enabled the Athenians to build the fouth wall of their citadel, and to lay the foundations of the long walls which were to connect the city with the port. Cimon might have enriched himfelf by this expedition in the moft honourable manner, but he chofe rather to expend his wealth upon his native city. He had a plain but plentiful repaft provided daily at his houfe for a numerous company, to which the pooreft citizens were made welcome. He not only fed the hungry, but clothed the naked, and was ready at all times to fupply the needy with fums of money to affift them in their various exigencies. Many of his public acts of benevolence carried with them the air of oftentation; it has, however, been afferted, that Cimon never aimed at courtefy, the populace being in reality attached to the ariftocratical party, which he alfo favoured in his political conduct. As a ftatefman, he confirmed the naval fuperiority of his country, not only by his fplendid victories, but by the wifdom of his policy. For, many of the Greek ftates, which were bound by treaty to furnifh fhips to the allied fleet, chufing rather to compound this fervice for money, he advifed the acceptance of their compofition, but at the fame time he would not hear of fuch an indulgence to the Athenians. The confequence of which was, that the other ftates loft all their practice in, and fpirit for, naval affairs, while the Athenians were kept in full exercife and difcipline. The Perfians renewed their hoftilities, which gave Cimon a new opportunity for achieving more victories: he then reduced the Thracians, who had revolted from the Athenians, joined the Perfians, and feized the gold mines in Thrace. About this period, the Lacedæmonians fent to requeft aid from Athens in fupport of their authority over the Helotes. Ephialtes oppofed the grant of it, with a view of keeping the Spartans in as depreffed a ftate as poffible, but Cimon vindicated their caufe, and prevailed. He was fent to their relief with a confiderable force, and obtained much honour in the fervice. Some time afterwards another body of Athenian troops, marching in to the affiftance of the Lacedæmonians, was difmiffed by them with circumftances of fufpicion, which offended the citizens of Athens, and indifpofed them againft the friends of Sparta. Pericles began to poffefs influence in Athens, as the head of the popular party, in conjunction with Ephialtes. They, envying the glory acquired by Cimon, conceived his ruin to be a neceffary ftep to the eftablifhment of their power. He was profecuted at their inftigation for having received bribes from Alexander, king of Macedon, to ftop the progrefs of the Grecian arms againft that country. Cimon, indignant at the ingratitude which he experienced for the fervices that he had performed, could fcarcely deign to vindicate his honour, which his enemies themfelves believed to be unfullied. He was, however, banifhed; but in a fhort time afterwards the Athenians became involved in a war with the Lacedæmonians, in which the armies of both nations met at Tanagra in Bœotia; a fevere action enfued, but neither of the contending parties could claim the victory. The battle was on the point of being renewed the next day, when Cimon appeared, and requefted to fight as a volunteer in his country's fervice. His petition was rejected, and himfelf commanded to leave the army. Before he retired, he addreffed himfelf to his friends, who had been confidered as acceffaries with him in the confpiracy againft the ftate, and intreated them to act in fuch a manner as to convince the Athenians, that they had not among them either braver or more honourable men than Cimon and his friends. They requefted him to leave his armour, fince their generals would not allow him to fight at their head. They formed clofe round it, to the number of about a hundred, and, rufhing amidft the thickeft of the foe, fought with undaunted courage till they were every man killed. Victory decided againft the Athenians, and the fubfequent events of the war caufed them to regret the abfence of Cimon, of whofe real patriotifm no one now entertained a doubt. Pericles, at whofe inftigation chiefly he had been fent away, himfelf drew up and fupported a decree for his recal. On his return, he fpeedily made peace between the Athenians and Spartans.

Such was become the conftitution of the Athenian commonwealth, and fo great the effects which the continuance of war had produced on the minds of the people, that, in order to preferve quiet at home, Cimon faw the neceffity of turning the fpirit of enterprife towards foreign conqueft, and againft the common enemy of Greece. He determined to attack Cyprus, that his countrymen might defift from making war upon the Lacedæmonians, or oppreffing their allies. For this purpofe, he took the command of a powerful fleet, part of which he detached to Egypt to diftract the attention of the Perfian government. With the remainder he attacked Citium and Malum, of which he made himfelf mafter. He afterwards defeated the Phœnician fleet, obtained a victory over the Perfian army encamped in Cilicia, and, re-embarking the troops, returned to Cyprus, and laid fiege to the principal city. In the camp before that place, Cimon died in the arms of victory. It is not known whether his death was occafioned by ficknefs, or by a wound which he had received. His remains were carried to Athens and buried there, and a magnificent monument was erected to his memory, which exifted there in the time of Plutarch. The death of this great man was not lefs honourable than his life had been glorious. When he found that he was about to expire, he gave fuitable directions to the principal commanders, ordered them to conceal his difeafe, and to embark immediately for Athens. Great as was the military character of Cimon, his wifdom, integrity, and moderation, and conciliatory conduct, were virtues for which the lofs

lofs of him was moft feverely felt and deplored. Others might command fleets and armies, and obtain victories, but they could not, or did not, like him, free Greece from civil feuds and domeftic wars. It has alfo been remarked in praife of this great man, that he, in the midft of wealth, as well as Ariftides in poverty, preferved the reputation of patriotifm unimpeached. Corn. Nepot. Plutarch. Univer. Hift.

CINA, or KINAH, in *Ancient Geography*, a town of Judæa, in the tribe of Juda. It was the town of the Cinæani, who defcended from Jethro, the father-in-law of Mofes. —Alfo, a town of Afia Minor, in Galatia, called Ciœna and Cenes.

CINABARENSIS, an epifcopal fee of Afia Minor, placed by the Greeks in Phrygia Salutaris.

CINABORIUM, a town of the Greater Phrygia.

CINÆDA, in *Natural Hiftory*, the name of a ftone found in the head of a fifh, of a whitifh colour, and oblong figure. The ancients fuppofed it prefaged tempefts when its furface looked dufky and obfcure; and, on the contrary, fair weather, when it looked bright and clear.

CINÆDOCOLPITÆ, a name given by Ptolemy to a people of Arabia Felix; he adds that their country was watered by the river Baetius, and affigns to them two towns and two villages fituated on the coaft of the Red Sea.

CINÆDOLOGIA, among the *Ancients*, a kind of fatyrical poetry, the chief fubject of which were the *Cinædi*.

CINÆDOPOLIS, in *Antient Geography*, an ifland of Afia Minor, in the Doride. Pliny fays that it was fituated at fome diftance from the continent, in the Ceramic gulph.

CINÆDUS, in *Antiquity*, is ufed to fignify a dancer or pantomime.

At firft they performed only on the ftage, but afterwards were admitted to the entertainments of princes.

CINÆDUS, or CYNÆDUS, in *Ichthyology*, the name of a fifh common in the Archipelago, about the fhores and rocks, fuppofed by many to be the fame fpecies with the alpheftes, and of the labrus kind, only with its back fin prickly all its length. It is of a yellowifh hue all over, blended and variegated with an admixture of purple: its fcales are rounded and indented; and its teeth very ftrong and firm, and difpofed in two rows in each jaw, and are long and fharp.

CINÆTRUM, in *Ancient Geography*, a mountain of Greece, in the Peloponnefus, towards the ifle of Cythera.

CINALOA, in *Geography*, a province of N. America, in the country of Mexico, or New Spain; bounded on the weft by the gulph of California, on the fouth by the province of Culiacan, on the eaft by Leon, and particularly by the high craggy mountains called Tepecfuan, or Topia, 30 or 40 leagues from the fea, and on the north by New Bifcay; from S.E. to N.E. it is about 100 leagues, and at its greateft breadth not above 40. It was firft difcovered in the year 1552 by Nunez de Guzman. The country is well watered, the air is pure and falubrious, the land is fertile, and produces all forts of fruit, grain, and cotton; and the rivers abound with fifh. The natives are robuft and warlike, and make ufe of bows with poifoned arrows, clubs of red wood, and bucklers; they are alfo induftrious, and manufacture cotton cloth for their own wearing. The political ftate of thefe people refembles that of the inhabitants of N. America. They have neither laws nor kings, nor have they any fpecies of authority or political government for punifhing any crime, or reftraining them in any part of their conduct. They acknowledge, indeed, certain caziques, who are heads of their families or villages; but their authority appears chiefly in war, and the expeditions againft their enemies. This authority the caziques obtain, not by hereditary right, but by their valour in war, or by the power and number of their families and relations. Sometimes they owe their pre-eminence to the eloquence with which they difplay their own exploits. Some tribes in this province feem to be among the rudeft people of America united in the focial ftate. They neither cultivate nor fow; they have no houfes in which they refide. Thofe in the inland country fubfift by hunting; thofe on the fea-coaft chiefly by fifhing. Both depend upon the fpontaneous productions of the earth, fruits, plants, and roots of various kinds. In the rainy feafon, when the country is fubject to fudden floods by the torrents from the mountains, deftitute of the fhelter of houfes, they gather bundles of reeds, or ftrong grafs, and binding them together at one end, they open them at the other, and fitting them to their heads, they are covered as with a large cap, which, like a penthoufe, throws off the rain, and will keep them dry for feveral hours. During the warm feafon, they form a fhed with the branches of trees, which protects them from the fultry rays of the fun. When expofed to the cold, which is extreme in December and January, (the weather, during the reft of the year, being very warm,) they make large fires, around which they fleep in the open air. In the mine Yecorato of this province there was found a grain of gold of 22 carats, which weighed 16 marks, 4 ounces, 4 ochavas; this was fent to Spain as a prefent fit for the king, and is now depofited in the royal cabinet at Madrid. The chief mining ftation is Sivirijoa.

CINALOA, a town of Mexico in the above-mentioned province, feated on a river of the fame name, which difcharges itfelf into the gulph of California. N. lat. 26°. W. long. 106° 10′.

CINARA, in *Botany*. See CYNARA.

CINAROCEPHALÆ, the fecond natural order in the tenth clafs of Juffieu, with the following general character and divifions. Flowers all flofculous; florets fometimes all hermaphrodite; fometimes neutral in the ray; rarely feminine intermixed with hermaphrodites. *Calyx* common, many-leaved, imbricated; fcales with or without fpines. *Receptacle* common, befet with hairs, or more frequently with chaff-like fcales; neutral florets often irregular; hermaphrodite ones five-cleft, regular, pentandrous; ftigma of the latter fimple or bifid, often without any marked diftinction from the ftyle. *Seed* downy; down capillary or plumofe. *Stem* herbaceous, rarely frutefcent. *Leaves* alternate, with or without fpines. *Flowers* various in colour, terminal, or rarely axillary.

I. True cinarocephalæ. Scales of the calyx fpinous. *Atractylis, cnicus, carthamus, carlina, arctium, cinara, onopordum, carduus, lappa, crocodilium, calcitrapa, feridia.* II. True cinarocephalæ. Scales of the calyx without fpines. *Jacea, cyanus, zoegea, rhaponticum, centaurea, pacourina, ferratula, pteronia, ftæhelina.* III. Anomalous cinarocephalæ. Calyxes one or few-flowered, aggregate. *Jungia, naffauria, gundelia, echinops, corymbium, fphæranthus.* Juffieu obferves that the genera of the laft divifion do not properly belong either to this natural order, or to the fucceeding one corymbiferæ, but are a link connecting both.

Ventenat has adopted the above divifions, adding in the firft, berardia and cirfium; difcarding pacourina, pteronia, and ftæhelina from the fecond; and retaining only gundelia, echinops, and fphæranthus in the third.

CINARUS, in *Ancient Geography*, an ifland fituated in the vicinity of that of Leros. It is mentioned by Athenæus, Plutarch, and Pliny, the latter of whom calls it "Cinara."

CINCARITANUS, an epifcopal fee of Africa in Bizacium. Some have thought that this fee was in the town of Cercina, in an ifland of the fame name.

CINCENSES, a people of Spain, placed by Pliny in

 the

the Tarragonenfis; they are probably the Cinnenfes, fo called from the name of the town Cinna.

CINCHONA, in *Botany*, (fo called from the Countefs del Cinchon, lady of a Spanifh viceroy, whofe cure is faid firft to have brought the Peruvian bark into reputation). Linn. Gen. 228. Schreb. 301. Juffieu 201. Vent. 2. p. 573. Gært. 204. Willd. 346. Quinquina; Lam. Encyc. Clafs and order, *pentandria monogynia*. Nat. Ord. *Contortæ*, Linn. *Rubiaceæ*, Juff.

Gen. Ch. *Cal.* Superior, one-leafed, five-toothed, permanent. *Cor.* monopetalous, tubular, funnel-fhaped, deeply five-cleft; tube long, obfcurely angular; fegments lanceolate, or linear. *Stam.* Filaments five, in the middle of the tube; anthers elongated, either fhorter than the tube, or projecting beyond it. *Pift.* Germ inferior, top-fhaped, obfcurely angular; ftyle the length of the ftamens; ftigma thick, either bifid or entire. *Peric.* Capfule crowned with the calyx, two-valved, two-celled; valves opening at their inner fide, turned in at their edges, and feparating, when ripe, fo as to have the appearance of two capfules. *Seeds* numerous in each cell, oblong, compreffed, bordered, attached to a central oblong receptacle.

Eff. Ch. Calyx top-fhaped, five-toothed. Corolla tubular, five-cleft. Stamens five, inferted into the middle of the tube. Capfule oblong, two-valved, two-celled, many-feeded.

* *Flowers tomentous*; *ftamens included.*

Sp. 1. C. *officinalis*, Linn. Sp. Pl. 1. Mant. 1. Lam. 16. Willd. 1. Lam. Ill. Pl. 164. fig. 1. Gært. tab. 33. fig. 4. Woodv. Med. Bot. tab. 200. (Arbor peruviana febrifuga; Rai. hift.) Common Jefuits' bark, or officinal Cinchona. "Leaves ovate-lanceolate, fmooth; capfules oblong." Vahl. A tall tree rather thicker than a man's thigh. *Branches* oppofite, covered with a reddifh brown bark, frequently rugged with obliquely tranfverfe chinks, and marked with the fcars of fallen leaves; upper ones a little compreffed. *Leaves* from two to three inches long, and one broad, remote on the flowering branches, but approximating on the others, oppofite, petioled, acute, fmooth on both fides, green above, paler underneath, marked with lateral fimple parallel nerves, a little curved at the fummit; petioles channelled above, convex underneath: ftipules fmall, acute, caducous. *Flowers* in a terminal, trichotomous panicle; peduncles flightly pubefcent, furnifhed with fmall acute oppofite bractes, at the bafe and about the middle; calyx-teeth fhort, acute; corolla flightly tomentous without, woolly within; fegments acute, fhorter than the tube; anthers the length of the tube; germ tomentous; ftigma thick, flightly bifid. *Capfules* half an inch long, oblong, fmooth, marked with obfcure raifed lines. A native of Peru, growing abundantly on a long chain of mountains, extending between two and five degrees of latitude to the north and fouth of Loxa. The proper time for cutting the bark is from September to November, the only feafon when, in that country, there is fome intermiffion from rain. Care muft be taken not to cut the bark wet; and if it fhould happen to be fo, it is carried directly to the low country to be dried.

This tree has been fuppofed to be the Quina-quina of the Peruvians, and has accordingly been given by many authors as one of its fynonyms. But the contrary has been proved by a fpecimen of the true Quina-quina fent by Monf. Condamine to Cromwell Mortimer, efq. fecretary of the Royal Society, about the year 1749, of which an engraved figure was then publifhed. Anthony Juffieu, who examined a dried fpecimen preferved in the herbarium of Jof. Juffieu, has pronounced it in his natural orders of plants, to be not a Cinchona, and to have no natural affinity with that genus; but to be a decandrous leguminous plant, which he has referred to Myrofpermum of Jacquin, a genus which has been united by Willdenow with the Myroxylon of Schreber. As the fpecimen fent by Condamine, is without fructification, this point cannot be abfolutely determined; but, from the defcription, the opinion of Juffieu feems highly probable, though it does not appear to be taken up by any other author as a diftinct fpecies. It has a triangular furrowed, pithy ftem, with alternate branches; and a thick, leafy, curioufly veined wing running along every angle, like a three-edged fword-blade, terminating here and there in a rounded form. A fragrant refin diftils from the trunk by means of an incifion. The feeds, called by the Spaniards Pepitas de Quinaquina, are of a brown colour, and woody fubftance, having the form of beans or flat almonds, and are enclofed in a kind of doubled leaf, (Qu. valves of the legume?) between which and the feed is found a little of the fame refin that diftils from the tree. Their chief ufe is to make fumigations, which are reputed cordial and wholefome, but their reputation is now on the decline. This tree grows abundantly in feveral provinces of Peru, as in the neighbourhood of Chucuifaca or La Plata, Tanja, &c. The natives make rolls or maffes of the refin, which are ufed for feveral other purpofes in phyfic, fometimes under the form of a plafter, fometimes under that of a compound oil made from the refin, and are fuppofed to promote perfpiration, ftrengthen the nerves, and reftore the motion of the joints of gouty people. In addition to thefe real or imaginary medical virtues, its bark is efteemed an excellent febrifuge, and before the difcovery of the tree of Loxa, was in great repute for curing tertian agues, &c. The Jefuits of La Paz or Chicuiapa gathered its bark which is intenfely bitter, and ufed to fend it to Rome, where it was diftributed under the true name of Quina-quina, and employed for the cure of intermittent fevers. The bark of Loxa, or Cinchona officinalis, having been brought into Europe, and particularly to Rome, by the fame means, the new febrifuge became confounded with the old one, and that of Loxa having been moft ufed, took the name of the firft, which is now almoft entirely forgotten, though the name Cafcarilla, or fmall bark, given to that of Loxa, feems to have been invented to diftinguifh it from fome other, undoubtedly the ancient Quina-quina. See Linnean Tranfactions, vol. iii. p. 59. with a figure copied from the original one.

Two forts of the Loxa bark are in ufe, the pale and the red, poffeffed of fimilar properties, but in a different degree, the latter being found by experience to be the moft powerful. It has been doubted whether they are the produce of different fpecies or of the fame plant from different parts of its furface, or, which is the fame thing, in different ftages of the growth of the bark itfelf. But the queftion feems to be nearly, if not altogether decided, by a drawing of the plant which produces the red kind, fent from Peru to Linnæus, and which appears to be a diftinct fpecies, though its fpecific difference has not been botanically determined. This drawing has been found in the Herbarium of Linnæus by Dr. James Edward Smith, and the ufe of it liberally granted to Dr. Woodville, who has publifhed in his Medical Botany a figure taken from it. See Medical Botany, vol. iii. p. 555. 2. C. *pubefcens.* Mart. 2. Willd. 2. Poiret Encyc. 17. Vahl. Act. Soc. Hift. Nat. Haf. 1. p. 19. tab. 2. "Leaves egg-fhaped, elongated at the bafe, pubefcent underneath; capfule cylindrical." *Root* perennial. *Bark* whitifh, whence it has been called white bark. *Branches* pubefcent on their upper part. *Leaves* from eight to ten inches long, and from five to fix inches broad, petioled, egg-fhaped, obtufe, narrowed at the bafe, and decurrent a little way along the petiole, pubefcent and tomentous underneath, hairy on the principal nerves, almoft fmooth above; nerves ftrongly marked, fimple, parallel, dividing into fmall fimple lateral veins; petioles about two inches

inches long. *Flowers* numerous, in large terminal panicles; bractes small at the base of the divisions of the peduncles; calyx small, with five sharp teeth; corolla scarcely an inch long, furnished with whitish hairs along its edge, and on its inside five-cleft; segments egg-shaped, shorter than the tube. *Capsules* an inch long, smooth, cylindrical, lessening a little at both ends. A native of Peru. Poiret suspects that the Cinchona hirsuta, purpurea & ovata, of Ruiz and Pavon in the Flora Peruviana, are nothing more than varieties of this species. They are thus severally characterized by those authors. C. *hirsuta*. "Leaves oval, thick, reflexed at the edges; the terminal ones somewhat heart-shaped: corolla with a purplish down; border hairy." C. *purpurea*. "Leaves oblong-oval and egg-shaped, purplish; panicle brachiate, large; flowers somewhat in corymbs; corollæ light purple; border hairy, white. C. *ovata*. "Leaves egg-shaped, downy underneath; panicle brachiate; flowers somewhat in corymbs; corollæ purple; border hairy." 3. C. *macrocarpa*, Mart. 3. Poiret 18. Willd. 3. Vahl. Act. Soc. His. Nat. Hafn. 1. tab. 3. Lambert. Gen. Cinch. tab. 3. (C. officinalis; Linn. Syst. Ed. 12. as far as relates to the description. C. officinalis; Linn. Jun. Sup. 144) "Leaves oblong, pubescent underneath, ribbed." *Root* perennial. *Branches* villous-tomentous. *Leaves* petioled, oblong, more than three inches long; somewhat coriaceous, smooth and shining above, pubescent underneath, with villous tomentous ribs; younger ones elliptical, hairy above, especially along the nerves; petioles an inch long; stipules two, lanceolate, caducous, connate at their base, smooth on the inside, often longer than the petioles. *Flowers* in a terminal, trichotomous, pubescent, panicle; peduncles of the ramifications an inch and a half long, compressed, with three nearly sessile flowers; bractes an inch long, linear-lanceolate; with others much smaller, awl-shaped ones at the base of each flower; calyx bell-shaped, pubescent, silky within; with five, sometimes six small sharp teeth; corolla an inch and half long, coriaceous, villous, almost tomentous; segments of the border lanceolate, obtuse, the length of the tube; filaments very short; anthers linear, longer than the tube; germ five-sided, obtuse; stigma bifid. *Capsule* two inches long, cylindrical, smooth, narrowed at the base; the two valves, as the fruit ripens, widely separating both at their base and summit. A native of Santa Fé. Vahl received it from Ortega.

** *Corollæ smooth; stamens projecting.*

4. C. *caribæa*, Linn. Sp. Pl. 2. Mart. 4. Poir. 1. Willd. 4. Jacq. Amer. tab. 179. fig. 95. Observ. Bot. 2. p. 47. Amer. pict. tab. 63. Gært. tab. 33. fig. 4. (C. Jamaicensis; Wright Act. Angl. Vol. 67. p. 504. tab. 10.) "Peduncles axillary, one-flowered." A tree from ten to twenty feet high. *Branches* dark brown, smooth, striated; often marked with brilliant oval, white or yellowish spots. *Leaves* two inches long or more, and about one broad, oval, lanceolate, narrowed at both ends, entire at their edges, thin, smooth on both sides; petioles short; stipules very small, broader than long, ciliated, acuminate. *Flowers* numerous; dusky yellow; peduncles not longer than the petioles, smooth; calyx smooth, short, somewhat cylindrical, with five short, acute teeth; tube of the corolla cylindrical; segments of the border long, linear, rather obtuse, smooth, longer than the tube; stamens a little projecting; anthers pale yellow, very long, narrow. *Capsule* opening from the top, black, with an even surface, very smooth, shining. *Seeds* oval, compressed, surrounded with a salient border. A native of Jamaica and Guadaloupe. It is called in Jamaica, Sea-side Beech. The bark in general is smooth and grey on the outside, though in some specimens rough and scabrous. Its flavour is sweet, with a mixture of the taste of horse radish, and the aromatics of the East, but when swallowed has the bitterness and astringency of the Peruvian bark. 5. C. *longiflora*, Poir. 2. Lamb. Gen. cinchon. p. 12. "Peduncles axillary, one-flowered; leaves linear-lanceolate, smooth; corolla very long." Nearly allied to the preceding, but distinguished from it by the remarkable length of the flowers, and by its longer narrower leaves. A tree. *Leaves* opposite, near together, with oblique lateral nerves, on moderately long petioles; stipules small, acute; segments of the border of the corolla linear, three or four times shorter than the tube. 6. C *corymbifera*, Mart. 5. Poir. 3. Willd. 5. Linn. Jun. Sup. 144. Forst. Act. Nov. Up. 3. p. 176. Flor. Aust. Prod. 88. "Leaves oblong-lanceolate; corymbs axillary." *Trunk* six feet or more in height, upright, round, smoothish, the thickness of the human arm. *Branches* round, spreading, opposite; upper ones herbaceous, compressed at the joints. *Leaves* three inches long, opposite, with an even surface, smooth, acuminate, quite entire, deep green, mid-rib purple underneath; petioles scarcely an inch long, round, spreading; stipules membranous, acute. *Flowers* white, red on the outside, dusky purple before they open; corymbs large, dichotomous; peduncles solitary, compressed at the tip, the length of the leaves; partial peduncles three, an inch long, angular, trifid; pedicels one-flowered; two, three, four, or more together, half an inch long, round, slender, erect; bractes very small, membranous, solitary, acute, at the base of each pedicel; corolla tubular; segments of the border shorter than the tube, narrow, obtuse, curved inwards; anthers erect, a little projecting; stigma thick, simple. A native of the islands of Tongatabu and Eaoowe in the South Seas, where it is cultivated for the odour and elegance of its flowers. Its bark is extremely bitter, and somewhat astringent, much resembling the common Jesuits' bark. 7. C. *lineata*, Mart. 6. Poir. 4. Willd. 6. Vahl. Act. Soc. Hist. Hafn. 1. tab. 4. Lambert. Gen. Cinch. tab. 6. "Panicle terminal; leaves egg-shaped, acuminate, smooth; capsules five-sided." A tree. *Branches* cylindrical, especially at the base, greyish, purple, and compressed near the top. *Leaves* two inches or more long, and one broad, on short petioles, not at all shining, bluntish, thin, smooth; nerves simple, lateral; stipules egg-shaped, acute. *Flowers* in large trichotomous panicles; peduncles compressed, three-flowered; bractes bristle-shaped; calyx-teeth long, awl-shaped; corolla two inches long or more; tube cylindrical; segments of the border linear, obtuse; germ five-sided, obtuse; stigma globular. *Capsules*, short, small, brown, smooth, oval, crowned with the teeth of the calyx. Nearly allied to C. floribunda and C. angustifolia; but differs from the latter in having much broader leaves, and from both in having its leaves rounded at the base with nerves visible on both sides. A native of the West Indies. 8. C. *floribunda*, Mart. 7. Poir. 5. Willd. 7. Vahl. Act. Soc. Hist. Nat. Hafn. 1. p. 123. Lam. Ill. Pl. 164. fig 2. Lamb. Gen. Cinch. tab. 7. (Cinchona floribus paniculatis, glabris, &c. Swartz Prod. 41; flor. Ind. Occid. 1. p. 375. Nov. Act. Acad. Nat. Curios. 9. p. 1. fig. 1. C. montana; Badier Journ. de Phys. feb. 1. 789. p. 129. fig. 1. Aust. Bot. Mag. p. 96. tab. 3. C. Sanctæ Luciæ; Philos. Trans. vol. 74. p. 452. tab. 19. Trachelium arborescens & fluviatile; Desport. Hist. Morb. S. Doming. 2. p. 231. Quinquina piton; Journ. de Phys. 1781. p. 169—179.) "Panicle terminal; capsules top-shaped, with an even surface; leaves elliptical, acuminate." A tree, thirty or forty feet high. *Trunk* straight, about a foot in diameter. *Branches* cylindrical at the bottom, obscurely tetragonal and purplish near the top. *Leaves* from eight to ten inches long, three or four broad, petioled, opposite, lanceolate-elliptic, acuminate, quite smooth,

ſmooth, even and ſhining on the upper ſurface, paler underneath, veined; nerves lateral, projecting, parallel, a little branched and confluent at their extremity; petioles an inch and half long; ſtipules oppoſite, ſheathing, oblong, obtuſe, caducous. *Flowers* at firſt white, afterwards purpliſh, numerous; panicle large; ramifications oppoſite, compreſſed, quite ſmooth; calyx-teeth very ſhort, awl ſhaped; tube of the corolla cylindrical, an inch long; ſegments of the border long, ſmooth, linear; ſtigma oval, entire. *Capſules* oblong, black, narrowed at the baſe. The bark of this ſpecies is more bitter and more aſtringent than that of C. officinalis. A native of St. Lucia, Martinico, Guadaloupe, and Hiſpaniola, where it bears the name of Pitton, becauſe it is found on the tops of mountains, which bear that name in the Weſt Indies, the mountains themſelves being called Morne. 9. C. *brachycarpa*, Mart. 8. Poir. 6. Willd. 8. Vahl. Soc. Hiſt. Nat. Hafn. 1. p. 24. Lamb. Gen. Cinch. tab. 8. Swartz. Prod. 42. Ind. Occid. vol. i. p. 378. "Panicle terminal; capſules inverſely egg-ſhaped, ribbed, leaves elliptical, obtuſe." *Leaves* large, ſmooth on both ſides; nerves alternate, lateral, a little branched at the ſummit; petioles ſhort; ſtipules ſhort, egg-ſhaped, acute. *Panicle* trichotomous, furniſhed with ſmall bractes at the diviſion of the peduncles; calyx-teeth ſhort, a little obtuſe; tube of the corolla rather long, cylindrical, ſlender; ſegments of the border linear, reflexed; ſtigma ſimple, globular. *Capſule* with ten ſtrong projecting ribs, connivent at their baſe. A native of Jamaica. The deſcription formed by Poiret from Lambert's figure. 10. C. *anguſtifolia*, Mart. 9. Poir. 7. Willd. 9. Swartz. Act. Stockh. Ann. 1787. p. 117. tab. 3? Prod. 42. Flor. Ind. Occid. 1. p. 380. Lam. Illuſt. Pl. 164. fig. 3. Lamb. Gen. Cinch. tab. 9. "Flowers panicled, ſmooth; capſules oblong, five-ſided; leaves linear-lanceolate, pubeſcent." A ſmall tree, from ten to fifteen feet high. *Trunk* upright, ſmooth, with a wrinkled aſh-coloured bark, which becomes brown and ſtriated near the root. *Branches*, ſlender, filiform, ſmooth. *Leaves* two or three inches long, ſcarcely half an inch broad, oppoſite, petioled, ſoft to the touch; ſtipules ſmall, egg-ſhaped, acute. *Flowers* white, odorous; panicle terminal, frequently with trifid ramifications; bractes ſmall, ſhort; calyxes ſhort, tubular, pubeſcent, with five upright awl-ſhaped teeth; tube of the corolla an inch long, ſmooth, ſlender; ſegments of the border the length of the tube, linear, narrow, obtuſe, reflexed. *Capſules* ſhort. *Seeds* very ſmall, ſmooth, rounded. A native of Hiſpaniola on the borders of rivers in a rocky ſoil. 11. C. *coriacea*, Poir. 8. (Cinchona nitida; Flor. Peruv.?) "Leaves ovate-oblong, ſhining on both ſides, coriaceous; panicles ſhort, ſmooth; anthers projecting, filiform." *Branches* with an even ſurface ſtriated; bark cinereous. *Leaves* oppoſite, petioled, narrowed at their baſe, obtuſe at their ſummit; nerves lateral, alternate, a little branched at the ſummit, projecting on the under ſurface of the leaf. *Flowers* in terminal panicles, with nearly dichotomous ramifications, on ſtiff ſmooth peduncles; calyx oblong, with upright acute teeth; corolla two inches long; tube ſtraight, cylindrical; diviſions of the border narrow, obtuſe, the length of the tube, ſmooth, reflexed; anthers upright, filiform. *Capſules* an inch long, blackiſh, cylindrical. A native of St. Domingo. The C. nitida of Ruiz and Pavon, Flor. Peruv. vol. ii. tab. 191. has inverſely egg-ſhaped, ſhining leaves; a brachiate panicle; light purple corollæ with a ſomewhat hairy border. Poiret judges it to be near a-kin to this ſpecies; but its panicle is larger, the tube of the corolla only half the length, and its capſule elongated; diminiſhing a little at its ſummit. 12. C. *grandifolia*, Poir. 9. Ruiz and Pavon Flor. Peruv. vol. ii. tab. 196. "*Leaves* oblong and oval, ſmooth; panicle brachiate; flowers ſomewhat in corymbs: corollas white, with a ſlightly villous border." A large tree with a denſely tufted head. *Bark* cinereous brown, reddiſh within, of an even ſurface, bitter and acidulous, without being unpleaſant. *Younger Branches* quadrangular, reddiſh. *Leaves* from one to two feet long, quite entire; ſhining on the upper ſurface, paler underneath, traverſed by purple veins; the principal ones furniſhed at their baſe with whitiſh ſilky hairs. *Stipules* oval, acuminate, caducous. *Flowers* white; corymb-like panicle about a foot long, and much branched, leafy; bractes ſmall, oval, acute; calyx purple, five-toothed; corolla an inch long; border a little villous within; ſtamens incloſed within the tube; anthers oblong, bifid at their baſe. *Capſule* large, ſcarcely ſtriated. *Seeds* oval, membranous at their borders. A native of Peru in the foreſts of the Andes in the neighbourhood of torrents. 13. C. *parvifolia*, Poir. 10. "Leaves egg-ſhaped, obtuſe, ſmooth; flowers panicled, twice-trichotomous, villous; corolla very ſmall. C. micrantha; Flor. Peruv. v. ii. tab. 194.? "Leaves oval, obtuſe; panicle large; flowers numerous, ſmall, white, with a woolly border." *Branches* ſmooth, upright, cylindrical. *Leaves* three inches long or more, one and a half broad, thin, entire membranous, petioled, with lateral nerves, narrowed at their baſe. *Stipules* oppoſite, ſheathing, awl-ſhaped, enlarged at the baſe. *Flowers* in a moderate panicle; peduncles axillary, oppoſite towards the extremities of the branches, upright, forked at the ſummit, each fork trichotomous, villous, compreſſed, with about three pedicelled flowers; bractes ſmall, at the baſe of the diviſions; calyx ſhort, tubular, villous; teeth ſcarcely viſible; corolla three or four lines long, pubeſcent on the outſide; ſegments of the border obtuſe. Stamens not projecting. *Capſule* unknown. A native of Jamaica. The Peruvian plant of Ruiz and Pavon has larger panicles; a corolla white on the inſide, reddiſh without, pubeſcent; and an oblong, acute, brown, capſule, with ten obſolete ſtriæ. 14. C. *lanceolata*, Poir. 11. Flor. Peruv. vol. ii. p. 51. "Leaves lanceolate-oblong; panicle brachiate, large; flowers ſomewhat in corymbs; corollas purple, inclining to roſe-colour; border hairy." A tall tree. *Bark* brown, a little ſpotted, yellowiſh within, very bitter, a little acid, but not unpleaſant. *Leaves* oppoſite, petioled, quite entire, ſmooth on both ſides, with purpliſh veins: petioles half an inch long; ſtipules flat, egg-ſhaped, obtuſe, connate at the baſe. *Panicle* terminal, wide-ſpreading; bractes ſmall, awl-ſhaped, caducous; calyx ſhort, purple; border of the corolla open, villous; ſtamens villous at the baſe. *Capſule* an inch long, oblong, narrow, ſlightly ſtriated, reddiſh brown, opening from the baſe to the ſummit. *Seeds* egg-ſhaped, with a membranous border, often much torn. A native of Peru on the mountains of Muyna. 15. C. *grandiflora*, Poir. 12. Flor. Peruv. vol. ii. tab. 198. "Leaves oval and inverſely egg-ſhaped, very ſlightly veined, coriaceous, white underneath; corymbs terminal; corollæ, large, ſmooth, white." A tree about twenty feet high. *Bark* cinereous brown, yellowiſh within, rather leſs bitter than the other ſpecies. *Branches* ſpreading; younger ones ſlightly tetragonal. *Leaves* ſpreading, rather near together, quite entire, ſhining green above, ſtipules obtuſe, ſlightly ſtriated. *Flowers* about thirty in a corymb, of a pleaſant ſmell, peduncled; bractes awl-ſhaped; calyx funnel-ſhaped, tubular, teeth upright, ſharp; corolla ſmooth; ſegments of the border reflexed; ſtigma two-lobed, oblong. *Capſule* narrowed at the baſe, marked with two furrows, opening from the ſummit to the baſe. *Seeds* numerous, very ſmall, with a linear membrane, on a large receptacle. A native of Peru in the foreſts of the Andes. 16. C. *roſea*, Poir. 13. Flor. Per. vol. ii. tab. 199. "Leaves oblong, obtuſely acuminate; panicle brachiate;

brachiate; flowers in corymbs; corollæ rofe-coloured; border tomentous at the edge." A tree, fifteen feet high. *Bark* brown, even, with cinereous fpots, very aftringent, flightly bitter. *Leaves* oppofite, petioled, very large, quite entire, fmooth, fhining, veined underneath; ftipules egg-fhaped, obtufe, purple, pubefcent on the outfide, connate at the bafe. *Flowers* in a terminal corymb; peduncles fpreading, pubefcent, compreffed; bractes egg-fhaped, acute; calyx fhort, purple; tube of the corolla fhort, flightly curved, cylindrical, fmooth at its edge, dilated into a tomentous border; fegments of the border fhort; ftamens villous at the bafe, fhorter than the border. *Capfule* a little recurved. A native of Peru in the forefts of the Andes. 17. C. *dichotoma*, Poir. 14. Fl. Peruv. vol. i. tab. 197. "Leaves oblong-lanceolate; peduncles terminal, dichotomous, few-flowered; capfules narrow, linear, long." A low tree. *Bark* brown, a little rugged, marked with whitifh fpots. *Branches* cylindrical, a little compreffed between the joints. *Leaves* flat; principal nerves oppofite; fmaller ones almoft reticulated; ftipules egg-fhaped, oblong, obtufe. *Flowers* in a loofe panicle; ramifications oppofite, with an expanded bifurcation. *Flowers* unilateral, nearly feffile. *Capfules* about two inches long, flightly ftriated; valves boat-fhaped. *Seeds* numerous, brownifh, with a narrow membranous wing. A native of Peru. 18. C. *caroliniana*, Poir. 15. (Pinkneya pubens; Michaux Flor. boreal. Amer. vol. i. tab. 13.) "Pubefcent; leaves egg-fhaped; flowers in a fafciculated panicle, axillary." Poiret. A middle-fized tree. *Branches* oppofite, villous, cylindrical, a little compreffed near the end. *Leaves* fix inches long, or more, three broad, petioled, narrowed at the bafe, pubefcent underneath, efpecially along the principal nerves, green and fmooth above; petiole fhort, pubefcent; ftipules two, lanceolate, acute, caducous. *Flowers* almoft feffile; calyx oblong, top-fhaped, divided at its orifice into five oblong, acute, nearly equal, caducous fegments, one of which often lengthens into the appearance of a leaf, or oval bracte, about an inch long, of a yellowifh white colour, as in muffærda frondofa; corolla tubular, cylindrical, pubefcent, an inch long or more; fegments of the border oblong, obtufe, reflexed, two-thirds fhorter than the tube; filaments attached to the corolla a little above the bafe, briftle-fhaped, upright; anthers projecting, almoft verfatile, obtufe, fhorter than in the other fpecies; germ enclofed in the tube of the calyx: ftyle the length of the ftamens; ftigma thick, almoft dichotomous. *Capfule* large, rounded, a little compreffed, marked with two oppofite furrows, obtufe, flattened and naked at its fummit, coriaceous, two-celled; partition reaching only to the middle. *Seeds* numerous, almoft round, with a fhort membranous ring. A native of Carolina and Georgia. Michaux on account of fome peculiarities found for it a new genus: but on account of its near affinity to Cinchona, Poiret has been induced to place it here.

Obf. Poiret obferves that Cinchona fpinofa of Lambert is evidently a fpecies of Catefbœa, near a-kin to catefbœa fpinofa of Linnæus.

Cinchona, in the *Materia Medica; Peruvian Bark.* This moft valuable medicine was firft introduced into Europe by the Jefuits as a cure for intermittent and other fevers, the ufe of which had long been known to the inhabitants of Peru and other parts of the American continent. It long remained a lucrative article of commerce to the order, whence it obtained the name of *Jefuits' Bark* or *Jefuits' Powder;* and it gradually (though not without confiderable oppofition at firft from the regular phyficians) rofe in reputation, and its ufe has extended over all the civilized world, fo that it has for many years been juftly efteemed as the moft fafe and powerful febrifuge which we poffefs.

There are three principal forts of Peruvian Bark in common ufe, and known in the European markets; befides which, there are many other varieties which are generally confounded with one or other of the above three forts, and which differ from them only by fome flight circumftances, fo as hardly to require a diftinct notice in a general defcription like the prefent. The three common forts now in ufe, are the *pale*, the *red*, and the *yellow* bark, and of thefe the two laft are comparatively of very recent date, and the red is now become very fcarce and is hardly ever imported, fo that in fact the pale and the yellow are the only barks now feen.

The chemical analyfis and fenfible properties of each, are on the whole extremely fimilar, but there is found an infinite variety in the proportion of conftituent parts.

The pale bark is brought over from the Spanifh main, in large bundles clofely packed up in goat and other fkins, and in pieces of different fizes, fome rolled up into fhort thick quills, and others flat. The outfide is brownifh and fcabrous, and generally covered with mofs; the infide is of a dull red or rufty iron colour. The beft fort breaks clofe and fmooth, and often minute fhining grains of a blackifh refin may be difcovered by clofe examination. It is very friable when chewed, and readily breaks down into a powder of a light cinnamon colour. The inferior forts are more tough and fibrous.

The yellow bark is in much larger pieces than the pale, and flatter and thicker. The outer part is fmoother, and the colour of the inner part is of a light red. It weighs lighter than the pale, and when reduced to powder, its colour is paler.

The red bark is alfo in larger and thicker pieces than the pale, and more convoluted than the yellow, though not actually forming quills or cylinders. It alfo breaks fhort, and the inner part is very red.

All the fpecies of cinchona have fo many properties in common, that the fame defcription is here meant to apply to all, except the contrary be particularly fpecified. The cinchona has a flight and fomewhat mufty fmell, though this may, perhaps, arife from the fkin in which it is packed. It requires to be chewed for a little while before the tafte comes out fully, which then is bitter and aftringent, with a flight aroma, but not fufficient to prevent its being difagreeable to moft palates.

The chemical analyfis of the cinchona has been attempted by fome able chemifts; and the effect of water, alcohol, and other reagents, as far as is neceffary for pharmaceutical purpofes, has been examined, with confiderable care. Enough has been learnt by them to decide on the beft mode of exhibition of this valuable remedy, but to the fcientific chemift much doubt ftill remains as to the true nature of many of the conftituent parts of this, as probably of all other refinous barks.

We fhall firft mention the fimpler experiments that relate more efpecially to pharmacy, and then defcribe fome more elaborate chemical proceffes.

The firft menftruum to be mentioned, is water. This fluid, whether hot or cold, acts fpeedily and powerfully on the cinchona. If this bark, thoroughly bruifed and reduced to coarfe powder, be boiled for a few minutes in water, it makes a clear decoction, which, when hot, is clear and reddifh, but on cooling it becomes very turbid and of a pale yellowifh or wheyifh hue, and a dark brown fediment is depofited. This decoction is intenfely bitter, gives a deep black with folutions of iron, and a very fmall quantity of precipitate with a folution of ifinglafs or glue. The latter circumftance fhews that it contains a little tannin; the blackening

with

with iron indicates gallic acid, and the bitternefs is occafioned by the prefence of an extractive matter, the peculiar quality of which will be prefently mentioned more at large. On keeping for fome days the fupernatant liquor of the decoction becomes almoft colourlefs and tranfparent, and the precipitate more copious. In time, though not very fpeedily, it grows mouldy and four, and acquires rather an offenfive fmell. A few drops of the ftrong acids added to the frefh decoction caufe a copious precipitate in a few minutes, and the clear liquor is left nearly without colour, but its tafte is ftill intenfely bitter.

If the fame portion of bark be boiled fucceffively with different portions of water, employing only a few minutes in each boiling, the contents of the feveral decoctions fhew, in fome meafure, the different degrees of folubility of the conftituent parts. The quantity of bitter extract given by thefe decoctions is by much the greateft in the firft, and goes on uniformly diminifhing till the whole is exhaufted. The gallic acid is more difficult of extraction, fo that the decoction will blacken the folutions of iron after it has ceafed to poffefs any other fenfible property. It has been mentioned, that the decoctions of bark grow turbid on cooling, and depofit a fediment in which much of the medicinal virtue is fuppofed to refide. This applies peculiarly to the firft decoction, which is loaded with foluble matter. If the turbid liquor be again heated, a part of the fediment is re-diffolved, but not the whole, and the proportion of infoluble matter is much increafed by the length of time employed in the boiling, and the furface expofed to the air. Hence it is inferred, and this is fupported by other chemical reafons which will be afterwards mentioned, that part of the foluble matter of the bark becomes permanently infoluble by abforbing oxygen from the air; and when thus rendered infoluble, it is alfo inferred, that it has loft moft of its medicinal properties, fo that the practical direction feems to be indicated in preparing this decoction, to boil the water on the bark only a fhort time, and in a covered veffel.

Cold water alfo diffolves very readily a confiderable portion of the foluble matter of the bark, and faturates itfelf with it in a digeftion of a few hours. This infufion is of a light brown red, and quite tranfparent. Its tafte is very bitter and lefs naufeous than the decoction. But by keeping it grows turbid, and are dinfoluble powder is precipitated. This infufion has been adopted in medicine in the proportion of about one part of powdered bark to eight of cold water, infufed for about fix hours, with occafional ftirring. It appears, however, from Dr. Lewis's experiments, that a fingle hour produces as ftrong a folution.

Alcohol digefted on bark acquires a deep brown colour, and a ftrong bitter and aftringent tafte. This folution, when evaporated to drynefs, leaves a black, fhining, brittle refin.

Dilute fpirit of wine alfo acquires a deep colour and ftrong impregnation with the active principle of the cinchona, by digeftion for a few days in a moderate heat. On increafing the heat, the colour deepens, and the fpirit becomes turbid, and a fediment is depofited which will not again entirely re-diffolve. The tincture of bark is made with dilute alcohol. The bark, after the utmoft effect of the alcohol, ftill yields fome foluble matter to water, and the decoction thus made is both bitter and aftringent. A part of this matter, which alcohol will not diffolve, and which water will, is the mucilage which the cinchona is found to contain in a notable quantity, and which, as in other cafes where mucilage is prefent, though infipid itfelf, ftrongly unites to a portion of the bitter extract and gallic acid, and appears to defend it from the action of the alcohol.

When a ftrong decoction of cinchona is evaporated at a boiling-water heat, it gradually becomes more and more turbid, deepens in colour almoft to a brownifh black; and at laft a dark pitchy-looking *extract* is left behind, which may be infpiffated to perfect drynefs if required, but in pharmacy is generally left of the confiftence of thick pafte. This extract has a ftrong, fomewhat faccharine, and agreeable fmell; to the tafte it is intenfely bitter and aftringent; it readily diffufes in water, but a part only is diffolved. The extract, of courfe, contains all the foluble parts of the bark blended together, partly in chemical union and partly in fimple mixture; and is, in fact, an extremely compound mafs. Its analyfis will be mentioned at the conclufion of this article. The directions given for preparing this extract in the pharmacopœias are extremely fimple and very fimilar. The cinchona is boiled with ten or twelve times its weight of water for an hour or two, and when the firft decoction is poured off, the bark may be again boiled with a frefh portion of water. The united decoctions are then evaporated at a boiling heat till they begin to be thick, and the drying to a due confiftence is then to be performed over a water-bath or in a ftoved room. The water-bath, however, is, in fact, feldom ufed, being very tedious; but the whole is performed by moft of the druggifts in this town in a fingle pan over a naked fire, which is kept very flack towards the end, and the extract conftantly ftirred to avoid burning.

The extract of bark is made in London only from the pale bark. The yellow bark does, indeed, furnifh a confiderable portion of extract, but the parts are apt to feparate fpontaneoufly, and it has not that uniform pitchy confiftence which the common extract has. The quantity yielded by different barks varies extremely, nor does there appear any other criterion to judge of the goodnefs of any fample of cinchona for this purpofe, except that nice and minute obfervation of colour, fracture, and the like, which is acquired by long and extenfive practice. It is reckoned a very good bark that yields a fourth of its weight of extract.

The cinchona is exhibited in medicine in a variety of forms. The fimple powder is by far the moft efficacious, and, in fact, is the only form that can be depended on for the cure of intermittents, and many other difeafes that require the vigorous ufe of this medicine. In London, the bark is powdered in large quantities in mills, where it is reduced to a moft impalpable duft. Some difficulty is found in bringing it entirely to this ftate, on account of the different degrees of brittlenefs of the feveral parts of the bark, fo that much of it would be loft in fine duft before the whole was powdered unlefs fome addition be made in the mill. To prevent this, fome add a fmall quantity of oil of almonds. This operation alfo gives the opportunity of practifing many frauds and adulterations; one of the commoneft of which is to mix in with the frefh bark that which has already ferved for the purpofes of decoction and tincture, and therefore has loft moft of its virtue, though not the whole.

The dofe of the powder, when good and genuine, is from twenty to fixty grains. The great inconvenience attending the powder is, the extreme difguft which it is apt to give to fick perfons, partly from the tafte, which is naufeous, and partly from the mere bulk and quantity of impalpable powder which muft be got down. This difguft too does not always go off, but as often increafes by ufe. Befides this inconvenience, the cinchona in any form is liable to produce coftivenefs, and as the powder of bark itfelf is little foluble in the ftomach, the whole alimentary canal is apt to be loaded and oppreffed with the accumulated dofes of the powder, fo that after a long courfe of this medicine, it is often difcharged from the bowels unaltered, and may be clearly

clearly detected in the ſtools. An occaſional purgative, therefore, is particularly neceſſary in a long courſe of this medicine.

The diſagreeable taſte and feel of bark in the mouth may be conſiderably checked and corrected by various ways. A cup of coffee with cream and ſugar will bear the addition of a doſe of the powder, with very little alteration in the taſte, if taken immediately on mixture. Red wine is often uſed as a vehicle, or water with a ſmall quantity of brandy or warm tincture. Liquorice is generally thought to cover the taſte moſt effectually; or elſe the powder may be made into a ſtiff electuary with a little ſyrup, and a lump of this, equal to the required doſe, may be wrapped up in wafer paper and ſwallowed.

In the liquid form the decoction is the moſt commonly uſed, and by far the beſt. The London College direct that one ounce of coarſely powdered bark be boiled with a pint and three ounces of water for ten minutes only, in a covered veſſel. The decoction, which is clear when hot, ſhould be ſlightly ſtrained before it cools; and whenever it is uſed, it ſhould be ſhaken, that the ſediment, which ſubſides when cold, be again mixed with the clear liquor. The decoction is undoubtedly the beſt ſubſtitute for the entire powder, if it is taken in large quantity. The uſual doſe is about two or three ounces, repeated a few times in the day, but it may be taken much more liberally without inconvenience. To increaſe its ſtrength, many practitioners add ſome of the powder to it, which by ſhaking will remain ſuſpended in it long enough for the purpoſe.

The cold infuſion of bark, made by macerating, in a moderate heat, one part of the bark with eight or ten of water for five or ſix hours, is alſo of conſiderable ſervice.

We find in different pharmacopœias an abundance of formulæ for the tincture of bark, all of which have nearly the ſame intention. Though proof ſpirit extracts much of the virtue of the cinchona, no quantity of tincture that could be borne without intoxication, could be depended on in diſeaſes where the cinchona itſelf was the proper remedy. The tincture therefore is only an auxiliary medicine, and is principally employed as a ſtomachic or mixed with the decoction. Two tinctures are in common uſe: the ſimple tincture, made merely with the bark and proof ſpirit; and the compound tincture (firſt brought into uſe by Dr. Huxham), in which the cinchona is combined with ſerpentaria and orange-peel.

When the extract of cinchona was firſt introduced, very ſanguine expectations were entertained of its ſuperior utility. As the inconveniences attending the entire powder were its bulk and the quantity of woody and apparently inert matter which it contained, it was expected that by exhauſting the bark of its ſoluble part, and exhibiting that portion in the condenſed form of extract, every poſſible advantage would be combined. But experience has not confirmed theſe expectations, at leaſt by no means to the full extent; for, whatever may be the cauſe, it is not found that doſes of ten grains of the extract are generally equivalent to forty or fifty of the powder, nor is it often that patients who reject the powder can bear the other in ſufficient quantity. Still, however, the extract is a valuable medicine, but it is chiefly employed in the form of pills as a ſtomachic, and in chronic diſorders, and ſeldom as a ſubſtitute for the powder in the more important caſes.

A very pure extract has long been known in pharmacy, and invented by the count la Garaye, and called after his name, or ſometimes *eſſential ſalt of bark*. The inventor firſt conceived the idea of preparing the ſuppoſed *eſſential* or finer part of the ſoluble matter of the cinchona as well as of other ſubſtances by infuſion in cold water, aſſiſted by violent and long continued agitation. This was peformed by La Garaye in ſmall mills, and with a complicated apparatus, which, however, is not neceſſary. This kind of extract is ſimply prepared by adding cold water to powdered bark, macerating them for two days with frequent ſtirring, and then evaporating very ſlowly the infuſion, which is ſtrongly impregnated with the active and ſenſible properties of the cinchona. The extract thus prepared, if the evaporation be well managed, has a fine granular appearance, ſtrongly reſembling a ſalt, and was taken for one by the inventor. It is ſcarcely ſoluble again in cold water, probably owing to the action of the air during the long evaporation, but it has not been examined in a ſatisfactory way. This preparation is tedious and expenſive, and though it is extolled by ſome writers, it by no means deſerves the high character given to it by the inventor, nor does it appear at all preferable as a medicine to the common extract.

A very valuable analyſis has been made by Fourcroy of one ſpecies of the cinchona from St. Domingo, (publiſhed in the 8th and 9th vol. of the Annales de Chimie,) which contains ſeveral new facts on the nature of the extract of cinchona, and which, therefore, may be with propriety introduced here. Some of the obſervations will, doubtleſs, apply to all the vegetable barks and to vegetable extract in general. The operations of this excellent chemiſt on the cinchona, as far as relate to extract, are the following: A pound (16oz.) of the cinchona reduced to powder was boiled twelve times ſucceſſively for a quarter of an hour, in about 26lbs. of water each time. The firſt decoction was a deep brown red, very bitter, and ſtrongly frothed in boiling. It yielded by evaporation in a gentle heat five ounces ſeven grains of a brown dry extract. The ſecond decoction was much leſs coloured, and gave only nine gros (of 72 grs. each) of extract. The third gave only two grains of extract. The taſte and other ſenſible qualities of the ſeveral decoctions alſo gradually diminiſhed to the twelfth, which was little elſe than pure water. The entire quantity of extract obtained was 9 oz. 56 grains. A ſecond ſeries of decoctions was then made with the ſame quantities, and preciſely in the ſame way, except that each decoction was allowed to cool before evaporation, during which the ſix firſt liquors depoſited in decreaſing quantities a quantity of black tenacious extract, apparently inſoluble in cold water. The ſupernatant liquors were then united, and the whole was evaporated to 2 lbs., and the depoſit on cooling was added to the other extracts, which altogether amounted to two ounces leſs than the quantity obtained in the former way, which two ounces, therefore, were eſtimated to be the quantity of extract retained in the 2 lbs. of clear decoction after cooling. This laſt, on mixture with alcohol, depoſited about an ounce of a whitiſh coheſive maſs, evidently different from the black extract, and which was proved to be a pretty pure mucilage. The black extract was then treated with boiling alcohol, by which all was diſſolved, except about $\frac{1}{15}$th, that remained behind in the form of a *red powder*. This laſt was digeſted in cold water, which diſſolved out of it a third of its weight of mucilage, ſimilar to that precipitated on adding alcohol to the decoction, and the remainder was, as before, a fine red powder inſoluble in cold water, and in alchol hot or cold. The alcoholic ſolution was then let to ſtand in the air for ſome days, when it depoſited a ſmall quantity of brilliant cryſtalline grains. It was then mixed with water, and in ſome hours a number of white flocculi ſeparated. Laſtly, the alcohol and water were totally evaporated, and there remained a large quantity of extract. By repeating this mode of analyſis with the entire extract obtained by the firſt proceſs, procefs, a pound of cinchona was found to yield the following foluble matter:

	oz.	gros.	grains.
Of mucilage - - - -	1	1	0
Cryftalline grains feparated from the folution - - -	0	1	0
Flocculi feparated by adding water to the folution - - -	0	1	12
Red powder infoluble in alcohol -	0	2	0
Extract left at the laft operation -	7	0	44
Lofs - - - - -	0	3	0
Total of extract obtained - -	9	0	56

Of thefe five conftituent parts of the entire extract, or foluble part of the cinchona, the author principally attends to the two latter, namely, the red powder, and the extract left behind after all the other fubftances have been feparated from it. With regard to the three firft, the mucilage very clofely refembled the common gum-mucilages; the cryftalline grains were infoluble in alcohol, and in cold water, but yielded to a large quantity of boiling water, were diffolved in alkalies, and gave fome ammonia by diftillation; and the flocculi refembled the gluten of wheat.

The red powder the author clearly fhews to be different from refin or any of the fuppofed immediate principles of vegetables. It is infoluble both in water and alcohol, but it unites with alkalies immediately and infeparably, and, therefore, effentially differs from the refins. Its colour is extremely durable, and little affected by oxymuriatic acid. The true nature of this refin was attempted to be explained by experiments on the extract.

This extract is, obvioufly from its quantity and its fenfible properties, the moft important part of the foluble portion of the cinchona. When quite dry, it is hard, fhining, and brittle, black, or deep brown, and intenfely bitter. It is totally and permanently foluble in hot alcohol, infoluble in cold water, but foluble in boiling water; from which, however, the greater part feparates on cooling, unlefs very largely diluted.

A fmall portion of the extract was diffolved in a large quantity of water and oxymuriatic acid gas paffed through. The firft effect of the acid was to give the folution a clear red colour, and to feparate a red flocculent powder. More of the gas deprived the liquor of colour, and much lightened that of the powder. After feparating all the red powder, which amounted to $\frac{1}{8}$th of the extract originally employed, the liquor (now faturated with the acid gas), was evaporated and left a black acerb-acid mafs.

The extract, therefore, appears, by this experiment, to be compofed of two parts; the one, capable of being converted by the oxymuriatic acid into this red powder, and the other not. The red powder thus produced artificially was found to refemble exactly that naturally contained in the entire extract, and which appears to be a conftituent part of the cinchona. Hence the author concludes, that the red powder confifts of extract altered by oxygenation, the oxygen in the one cafe of its production being abforbed from the atmofphere by the decoction, during its long evaporation, and in the other, furnifhed by the oxymuriatic acid. In confequence of this hypothefis, he adds, that the quantity of this red powder is in direct proportion to the time of expofure to the atmofphere; and as it may be inferred to be very inert as a medicine, from its fparing folubility, hence the practical direction of preparing the decoction of bark by a hafty boiling, and in a covered veffel.

Thefe experiments, however, by no means warrant the inference that the red powder is nothing but fuper-oxygenated extract, even admitting that the fubftance formed by the oxymuriatic acid is effentially the fame as that feparated fpontaneoufly by expofure to air. The inquiries of other chemifts have fhewn that this fubftance contains lime in one form or other, fince, when calcined, it leaves chiefly carbonat of lime; and alfo, if it is nothing but oxygenated extract, it is not eafy to affign a valid reafon why only a part of any given portion of extract fhould be able to be thus changed.

Thefe are the chief experiments relating to the fubject of extract contained in this elaborate inquiry; and though they are ingenious, and apparently accurate, they certainly fhew that very much remains to be done in this part of chemical analyfis, and that the common diftinction of thefe fubftances into refin, gum, gum-refin, &c. is extremely imperfect and unfatisfactory; though the deficiency of real information on the nature of many of the moft important articles of the vegetable Materia Medica leaves little to the compiler but to repeat the fcanty matter of fact fuch as he finds it.

The cinchona has been, and is conftantly employed in a great variety of difeafes, which we fhall not attempt to enumerate in this place. The general operation of this admirable drug is, to reftore and increafe the general health and ftrength, to improve the appetite, and promote all the functions of the body. This it effects in a gradual way, and moftly without any fenfible operation, except that of ftrengthening the pulfe. Some inconveniences occafionally occur, which either forbid its ufe, or require fome additions to counteract them. Sometimes it increafes the fymptoms of general fever, heat, thirft, reftleffnefs, &c. and in this cafe too, it often is rejected by the ftomach, after having been taken for fome hours. Hence it can feldom be borne, and often does mifchief in acute fever; fo that in curing intermittents by its means it muft be employed only in the perfect intervals between the paroxyfms. Its effects on the bowels are various and oppofite. Often it purges, and as often it brings on a coftive ftate, each of which requires the proper correctives.

Befides the original ufe of the bark in intermittent and remittent fevers, it is fcarcely lefs extenfively or certainly ufeful as an auxiliary to furgery, in fupporting and improving the vis vitæ under extenfive bodily injuries, large ulcerations, compound fractures, and cafes where gangrene is threatened, or actually eftablifhed. In fcrophulous cafes alfo, and indurated and ulcerated glands, it has often a moft happy effect in bringing on healthy fuppuration and granulation of the fore.

The cinchona is fcarcely ever employed externally, except as a ufeful aftringent gargle.

CINCINATO, Romulo, in *Biography*, a Florentine painter, who was born early in the 16th century, and is believed to have been the difciple of F. Salviati. He was one of the principal artifts employed by Philip II. in the Efcurial, where, in the great cloifter, he painted many excellent frefcos; in the church likewife are feveral of his pictures, "particularly one of San Geronimo reading, and another of the fame faint dictating to his difciples; and in the choir two frefco paintings, taken from paffages in the life of San Lorenzo." Many works of his exift at Guadalaxara, in the palace of the Duque del Infantado, a grandee of high family. The moft celebrated of his pictures is a Circumcifion, in the church of the Jefuits at Cuenca, where he fucceeded fo admirably in the fore-fhortening of one of the figures, which is reprefented with its back turned towards the fpectator, that he is reported to have declared that he prized

prized one limb of this figure more than all his works in the Escurial. He died at an advanced age, universally lamented, in the year 1600. Cumberland. Lanzi, Storia Pittorica. Orlandi.

Cincinato, Diego de Romulo, was the son and scholar of the preceding; he entered into the service of Don Fernando Enriquez de Ribera, third duke of Alcala, and went with him to Rome, upon his being appointed ambassador for the purpose of doing homage from Philip IV. to pope Urban VIII. He painted the portrait of his holiness three several times, with such success, that, besides many handsome presents heaped upon him, he received the honour of knighthood from the hand of cardinal Trexo Parriagua, a Spaniard. This happened in the year 1625, and in the year following he died, and was buried in the church of San Lorenzo, at Rome. He left a brother named Francesco, upon whom, at the request of Philip IV. the pope conferred the honour of knighthood, after the death of his brother. Francesco died at Rome, in the year 1636. Cumberland. Lanzi, Storia Pittorica.

CINCINNATI, in *Geography*, a pleasant and flourishing town in the United States of America, in the state of Ohio, and county of Hamilton, seated on the Ohio river, and commanding a picturesque view of the surrounding country. It is opposite to the mouth of Licking river, and the little town of Newport, which is built at the point formed by the junction of that river with the Ohio. The settlement commenced in 1789, and the town was incorporated in 1802. It contains upwards of 300 houses, and has a printing-press which issues a weekly paper. Cincinnati was for several years the seat of government for the north-western territory, and it is in the line of communication with the chain of forts that extend from fort Washington, near the upper end of the town, towards the west. It lies six miles below Columbia, and this as well as the other place are situated between Great and Little Miami rivers. N. lat. 39°. 5′ 54″. W. long. 85° 44′.

Cincinnati, *Society of*, a society formed in the United States of America towards the close of the year 1783, by the officers of the army, just before the disbanding of it; so called after the Roman dictator, Cincinnatus, and intended to perpetuate the memory of the revolution, the mutual friendship, and the union of the states; and also to raise a fund for the relief of poor widows and orphans whose husbands and fathers had fallen during the war, and for their descendants. In October 1783 general Washington subscribed himself president of this order. The general society, which was to meet at least once in three years, was divided into state-societies, which were to meet annually on the 4th of July, the anniversary of American independence. In order to raise a fund for the benevolent purposes of the society, each member was to subscribe one month's pay to the general treasury, and the fund was to be augmented by private donations. The interest only of the money thus raised was to be expended in acts of charity. The members of the institution were to be distinguished by wearing a medal, emblematical of the design of the society. The device was a bald eagle of gold, and it was suspended by a deep blue ribband edged with white, descriptive of the union of America and France. The emblems borne on the breast of the eagle were the following: the principal figure Cincinnatus, and three senators presenting him with a sword and other military ensigns; on a field in the back ground his wife standing at the door of the cottage, and near it a plough and other implements of husbandry; round the whole, "Omnia reliquit servare rempublicam." On the reverse, the sun rising, a city with open gates, and vessels entering the port; fame crowning Cincinnatus with a wreath, inscribed "virtutis premium;" below, hands joining, supporting a heart, with a motto "esto perpetua;" round the whole, "Societas Cincinnatorum instituta, A.D. 1783." The honours and advantages of this society were to be hereditary in the line of the eldest male heirs, and in default of male issue, in that of the collateral male heirs. Honorary members were to be admitted, but without the hereditary advantages of the society, and provided their number should never exceed the ratio of one to four of the officers or their descendants. The ostensible views of this society, however honourable and praise-worthy, could not screen it from popular jealousy; and it was alleged by an able writer, that the principles on which the society was formed would, in process of time, introduce and establish an order of nobility in the country, which would be repugnant to the genius of the republican governments of America, and dangerous to liberty. Early in the year 1784 the provinces of Pennsylvania and Massachusetts declared the institution unjustifiable, and their resolution to discountenance it. The province of Rhode Island proceeded so far as to annul the privileges of all the subjects of its state who should be members of this society, and to declare them incapable of any office under government. In consequence of this alarm, the Cincinnati, in their first general meeting convened at Philadelphia, May 3, 1784, thought proper to new model the institution of their society. They professed to withdraw the claim of hereditary honour, to disclaim all interference with political subjects, and to place their funds under the immediate cognizance of the several legislatures, through the medium of a general charter. Indeed they relinquished without hesitation every thing in their new constitution, except their personal friendships, of which they could not be divested, and the acts of beneficence which it was their intention should flow from them. With these professions, however, they retained their funds, their general meetings, and their ribbands.

Cincinnatus, Lucius Quintius, in *Biography*, an illustrious Roman, who flourished towards the close of the 3d century from the building of the city. Though his means were so small as to induce him to cultivate a small farm with his own hands, yet he was of a patrician family. In the year 292, when the city was in a very disturbed state on account of the dissensions between the tribunes and the senate, Cincinnatus was created consul. He had for some time relinquished all views of ambition, and would gladly have been excused entering upon public life. He was naturally attached to the patrician party, and owing to the banishment of his son Cæso for supporting the cause of the senate, he was still less inclined to keep terms with the plebeians. He reproached the senators for their pusillanimity, and the tribunes of the people for their insolence, and prevented the bringing forward any motion for the Terentian law in favour of the people. He had been elected to his office to complete the year only of the consul Valerius Poplicola, who had been slain in recovering the capitol from Herdonius, an ambitious Sabine, that had rendered himself popular by opposing the laws, and by promising freedom to the slaves, and an ample participation of the spoils of the rich to those in the lower ranks of life. When his time of serving the office of consul was nearly expired, the senators proposed to re-elect him for another year, which he peremptorily refused, as being contrary to their own resolution against the continuation of magistracies to the same person. He had not, however, long retired from public concerns when the city became threatened with imminent dangers from an invading army of the Æqui: Cincinnatus was unanimously created dictator. At that time he was diligently cultivating a small farm acrofs the Tiber. He was found by the perfons deputed from the fenate engaged in ruftic labour; and, after mutual falutations, he was defired to put on his *toga* to hear the commands of the fenate. His wife Racilia quickly brought the garment from their cottage, and as foon as he was dreffed in it, they faluted him dictator, and at the fame time explained to him the nature of the public danger. A veffel was already prepared for his paffage, and he was received on the oppofite bank with every token of refpect and deference. Cincinnatus headed the Roman army, and, after a defperate engagement, the Æqui were obliged to fubmit to a treaty propofed by the conqueror, and to give up their principal officers, arms, and baggage. Cincinnatus divided the fpoils among his foldiers, and returned triumphant to Rome, where he was received as the faviour of the ftate. The fenate would gladly have enriched him, but he declined their offers: he retained his dictatorial authority only till the principal witnefs againft his fon had been convicted of falfe teftimony, and Cæfo recalled, and then abdicated on the fixteenth day the fupreme dignity to which he had been appointed for fix months, having in that fhort time refcued a Roman army from deftruction, and defeated a powerful enemy. "He returned," fays a good hiftorian, "a triumphal hufbandman, having finifhed a war within fifteen days, as if he had been in hafte to refume his interrupted labours." Twenty years after this Cincinnatus was again made dictator, and though then eighty years of age, this veteran poffeffed all the intrepidity and courage of youth. He was now called upon to fupprefs a confpiracy, at the head of which was Spurius Mælius, a rich knight, who had monopolized the corn of Tufcany, and by his liberality to the idle and the poor had feduced a number of partizans to his caufe fufficient to endanger the fafety of the republic. As foon as Cincinnatus had been appointed dictator, he ordered Mælius to appear before him in the forum: the knight, confcious of his guilt, and forefeeing the danger to which he was now expofed, attempted to make his efcape, when he was purfued by Ahala the mafter of the horfe, and killed on the fpot. The dictator applauded the deed, and commanded the confpirator's goods to be fold, his houfe to be demolifhed, and his wealth to be diftributed among the people. Cincinnatus did not long furvive the glory of this action: he died highly refpected by his fellow-citizens, and with the confcioufnefs of having been eminently ufeful to the ftate of which he had fo long been a member.

CINCINNATUS, in *Geography*, the moft fouth-eafterly of the military townfhips in the ftate of New York, in America. It has on the weft Virgil, and Salem in Herkamer county on the eaft, and lies on two branches of Tioughnioga river, a north-weftern branch of the Chenango. The center of the town lies 53 miles S.W. by W. of Cooperftown, and 39 S.E. by S. of the S.E. end of Salt Lake. N. lat. 42° 30′.

CINCIUS ALIMENTUS, LUCIUS, in *Biography*, an early Roman hiftorian and antiquary, who flourifhed during the fecond Punic war. He is now known only from references to his works by other celebrated writers. Cincius is quoted by Livy as of great authority; and from the works of Dionyfius Halicarnaffus, it appears that he wrote a hiftory of the wars of Hannibal in the Greek language. Aulus Gellius has referred to his treatife on military affairs. Macrobius refers to a work which he wrote on the Fafti; and Feftus fpeaks of feveral books of his on fubjects connected with Roman antiquities. From thefe references, there can be no doubt that Cincius was an author, whofe works, had they come down to us, would have done honour to the age in which he lived, and have been a valuable addition to our prefent literary treafures.

CINCLUS, in *Ornithology*, a fpecies of TRINGA, which fee; the flint or ox-eye of Ray and Willughby, the leaft fnipe of Ray and Sloane, the wag-tail of Brown, the fanderling of Albinus, and the purre of Pennant and Latham.

CINCLUS is alfo a fpecies of STURNUS, (which fee), black with a white breaft; the water-ouzel or water-crake of Ray, Willughby, Pennant, and Latham.

CINCLUS *tertius*. See GIAROLO.

CINCTURE, in *Architecture*, the orlo or ring at the top and bottom of a column, which feparates the fhaft at one end from the bafe, and at the other from the capital. The upper cincture is likewife called *collarino*; (fee *Plate* XVI. of *Architecture*). Cincture is alfo ufed to denote the aftragals or other mouldings, which are in fome inftances applied to conceal the joints in the fhaft of a column, as in the baldaquin of St. Peter's, and at the Val-de Grace at Paris.

CINCTUS, in *Ancient Military Language*. This appellation was given to a Roman foldier rated or ceffed as bound to carry arms and fight for his country. At the fame time, the *cingulum* (girdle or belt) was given to him. And the taking of it from him was regarded as a load of ignominy and difgrace.

CINDIA, in *Ancient Geography*, a town of India, placed by Ptolemy on this fide the Ganges.

CINDIA, a town of Caria, in the vicinity of Jaffus and Bargilia.

CINDRAMORUM, an epifcopal town of Afia Minor, in Caria.

CINEFACTION. See CINERATION.

CINEGUILLA, in *Geography*, a town of North America in New Mexico, in the province of Sonora; N. lat. 29° 48′, W. long. 111° 30′. Whilft the Spaniards were penetrating thefe countries during a war of three years, which terminated in 1771, by the final fubmiffion of the natives, they entered a plain at this place, 14 leagues in extent, in which they found gold in grains, at the depth of only 16 inches, of fuch a fize, that fome of them weighed 9 marks, and in fuch quantities, that in a fhort time, with a few labourers, they collected 1000 marks of gold in grains, even without taking time to wafh the earth that had been dug, which appeared to be fo rich, that perfons of fkill computed that it might yield what would be equal in value to a million of pefos. Before the end of the year 1771, more than 2000 perfons were fettled at Cineguilla, under the government of proper magiftrates, and the infpection of feveral ecclefiaftics.

CINERARIA, in *Botany*, (fo called from the cinereous or afh-coloured appearance of many of its fpecies), Linn. gen. 957. Schreb. 1294. Juff. 181. Vent. 2541. Gært. 1021. Clafs and order, *fyngenefia polygamia fuperflua*. Nat. ord. *Compofitæ difcoideæ*, Linn. *Corymbiferæ*, Juff.

Gen. Ch. *Cal.* common fimple, many-leaved; leaves nearly of equal length. *Cor.* compound; hermaphrodite, florets in the difk, tubular, five-cleft, regular; femi-florets female, ligulate, forming the ray when prefent. *Stam.* in the hermaphrodite; filaments filiform, fhort; anthers united in a hollow cylinder, five-cleft at the top. *Pift.* in the hermaphrodite, germ oblong; ftyle filiform, the length of the ftamens; ftigmas two, almoft erect; females, germ oblong; ftyle filiform, fhort; ftigmas two, oblong, bluntifh, revolute. *Peric.* the permanent calyx. *Seeds* linear, quadrangular; down generally capillary, copious. *Rec.* naked, flattifh.

Eff. Ch. Calyx fimple, many-leaved, equal; down generally fimple, receptacle naked.

In

In a few fpecies there are two or three fmall fcales at the bafe of the calyx, by which they fhew an approximation to fenecio, and feem to intimate that there is no natural line of diftinction between the genera. Gærtner afferts, that the fphacelated tips of the calyx-fcales in fenecio do not form a fufficient generic difference. He has therefore founded the diftinction between that genus and cineraria on the form of the leaves, retaining in his genus cineraria only thofe that have undivided leaves, and removing all that have pinnatifid ones to his jacobæa, part of the fenecio of Linnæus. But we prefume that no found botanift will ever agree with him in admitting any thing relative to the leaves into the effential character of a genus.

* *Flowers without a ray.*

Sp. 1. C. *nivea*, Willd. 1. (Doria nivea, Thunb. Prod. 155. nov. gen. p. 163.) "Leaves linear, tomentous; flower generally folitary, terminal; ftem fhrubby." *Root* perennial. *Flowers* peduncled. A native of the Cape of Good Hope. 2. C. *undulata*, Willd. 2. (Doria undulata, Thunberg. C. fpathulata, Lam.?) "Root-leaves elliptical, petioled, undulated, fmooth; flower folitary, terminal." *Root* annual, fibrous. *Root leaves* numerous, curled, revolute at the edges, erect, a finger's length; petioles longer than the leaf, linear, ftriated, fomewhat villous. *Stem* a foot and a half high, folitary, fometimes two, cylindrical, fcabrous, fimple, erect. 3. C. *alata*, Linn. jun. Suppl. 374. Mart. 19. (Doria alata, Thunb.) "Root perennial; ftem herbaceous; leaves inverfely egg-fhaped; flowers in corymbs." *Stem* two feet high, upright, a little branched, angular, with an even furface. *Leaves* quite entire, with an even furface. *Corymbs* at the top of the ftem, leaflefs; calyx fix-cleft, egg-fhaped, with an even furface; florets about fixteen; fome of them in the margin female, naked. A native of the Cape of Good Hope. 4. C. *fpinulofa*, Lam. 19. "Leaves embracing the ftem, fomewhat fpatule-fhaped, fpinous-toothed at the edges, fmooth; corymb panicled." Whole plant fmooth, of a flightly glaucous green colour. *Stem* a foot high or more, herbaceous, full of pith, cylindrical, ftriated, a little branched. *Leaves* alternate, ending in a fhort point; upper ones fmall, almoft lanceolate, entire. *Flowers* yellow, fmall, numerous. A native of Africa, communicated by Sonnerat. 5. C. *perfoliata*, Linn. jun. Suppl. 375. Mart. 23. (Doria perfoliata, Thunb.) "Leaves egg-fhaped, embracing the ftem; peduncles one-flowered, elongated." Whole plant glaucous, inclining to flefh coloured. A native of the Cape of Good Hope. 6. C. *denticulata*, Linn. jun. Sup. 375. Mart. 22. (Doria denticulata, Thunb.) "Leaves lanceolate, fmooth, toothed; flowers panicled." *Leaves* almoft all radical, long; ftem-ones fmall, chiefly at the ramifications. A native of the Cape. 7. C. *ferrata*, Willd. 6. (Doria ferrata, Thunb.) "Leaves inverfely egg-fhaped, oblong, ferrated, tomentous underneath; ftem branched near the top; branches one-flowered." A native of the Cape. 8. C. *elongata*, Mart. 20. Willd. 7. (Doria elongata, Thunb.) "Leaves fomewhat heart-fhaped, bitten; peduncles very long, fubulate-fcaly." *Stem* a foot and a half high; erect, branched, reddifh, tomentous at the ramifications. *Leaves* an inch long, petioled, diftant, unequally crenate, fmooth, rather obtufe; petioles the length of the leaves, a little decurrent at the bafe. *Flowers* yellow, peduncles terminal, one-flowered; calyx quite fimple; leaves from twelve to fourteen, lanceolate, the length of the flower. A native of the Cape. 9. C. *erofa*, Willd. 8. (Doria erofa, Thunb.) "Stem herbaceous, decumbent; leaves lyre-fhaped, toothed, flowers panicled." *Leaves* fcabrous, pubefcent underneath, with minute prominent papillæ; lateral lobes unequal, fimple; terminating one larger, kidney-fhaped, three-lobed. A native of the Cape, near Ribek caftel and Paardeburg. 10. C. *fonchifolia*, Linn. Sp. Pl. 5. Lam. 6. Mart. 5. Willd. 9. (Doria fonchifolia, Thunb. Jacobæa fonchi folio, Breyn. Prod. 3. tab. 21. fig. 1.) "Leaves embracing the ftem, differing in fhape." Linn. *Stem* fmooth, leafy. *Flowers* terminal, large. *Lower leaves* petioled, irregularly lobed; upper ones embracing the ftem, heart-fhaped, acute, entire. A native of the Cape. 11. C. *incifa*, Willd. 10. (Doria incifa, Thunb.) "Leaves oblong, fmooth; lower ones gafh-toothed; upper ones quite entire; flowers terminal." A native of the Cape. 12. C. *pinnatifida*, Willd. 11. (Doria pinnatifida, Thunb.) "Leaves pinnatifid, toothed, fmooth, petioled; flower folitary, terminal." *Stem* a foot high, herbaceous, cylindrical, a little zig-zag, branched. *Branches* alternate, filiform, elongated, leaflefs at the top. *Leaves* three inches long, fcattered, erect; lobes nearly oppofite, egg-fhaped, fcarcely a line long. A native of the Cape. 13. C. *bipinnata*, Willd. 12. (Doria bipinnata, Thunb.) "Leaves twice-pinnated, linear, fmooth; flowers panicled." A native of the Cape.

** *Flowers with a ray.*

14. C. *filiformia*, Willd. 13. Thunb. Prod. 154. "Leaves linear, fmooth; flowers panicled." A native of the Cape. 15. C. *cacaloides*, Linn. jun. fup. 174. Mart. 21. Willd. 14. Thunb. Prod. 154. "Leaves cylindrical, oblong, flefhy; panicle terminal, elongated, few-flowered; peduncles alternate." A native of the Cape. 16. C. *lineata*, Linn. jun. fup. 375. Mart. 24. Willd. 15. Thunb. Prod. 154. "Leaves lanceolate, tomentous underneath, ferrated at the tip, toothed at the bafe." *Stem* a foot high and more, herbaceous, erect, ftriated, hoary. *Leaves* alternate, nearly feffile, three-nerved underneath. *Flowers* with a yellow ray; panicle twice compound, ftiff, much longer than the leaves, fomewhat faftigiate, hoary; calyx fmall; down twice the length of the calyx. A native of the Cape. 17. C. *americana*, Linn. jun. fup. 373. Mart. 18. Willd. 16. "Stem fhrubby; panicles axillary; leaves alternate, petioled, broad-lanceolate, ferrated, fmooth on the upper furface, hoary underneath." Whole plant clothed with a woolly epidermis, which has the appearance of a thin membrane, and is eafily abraded. The branches, petioles, peduncles, and under furface of the leaves, all whitifh. *Stems* woody. *Leaves* veined, with the confiftence of evergreens. *Fowers* with a ray, apparently yellow; peduncles with fcaly bractes, rarely two-flowered; calyx and leaves fo equal as to feem only one, with a few irregular fcales at the bafe. *Leaves* oblong, rather obtufe, flightly heart-fhaped at the bafe, coriaceous. A native of North America, obferved by Mutis. 18. C. *repanda*, Mart. 28. Willd. 17. Forft. Prod. n. 295. (Brachyglottis; Forf. ch. gen. tab. 46.) "Panicle twice compound, divaricated, terminal; leaves oblong, repand-finuate, tomentous underneath; ftem arboreous." *Root* perennial. A native of New Zealand. 19. C. *rotundifolia*, Mart. 27. Willd. 18. Forft. Prod. n. 294. "Panicles few-flowered; leaves petioled, roundifh, egg-fhaped, quite entire, tomentous underneath; ftem arboreous. *Root* perennial. A native of New Zealand. 20. C. *geifolia*, Linn. Sp. Pl. 1. Mart. 1. Lam. 1. Willd. 19. (Othonna glifolia, Kniph. Ant. 5. n. 62. Jacobæa Comm. Hort. 2. tab. 73. Seb. Muf. 1. tab. 22. fig. 3.) "Peduncles branched; leaves kidney-fhaped, rather orbicular, fomewhat lobed, toothed, petioled, Linn. Sp. "Peduncles branched; leaves kidney-fhaped, narrowed, fomewhat lobed, pubefcent; petioles eared at the top. β. "Petioles unequally appendicled, Lam. Jacobæa, Pluk. Mart. tab. 421. fig. 4. *Root* perennial. *Stem* a foot high, or more, much branched, cylindrical, cloth-

 ed

ed with a cottony down. *Leaves* green on the upper surface, hoary underneath. *Flowers* yellow. The variety β is larger, and its petioles furnifhed with more remarkable appendicies. A native of Africa. 21. C. *aurita*, Willd. 20. L'Herit. fert. ang. " Flowers in corymbs; leaves heart fhaped, fomewhat angular, tomentous underneath; petioles with two ears at the bafe." *Root* perennial. *Flowers* purple. 22. C. *cruenta*, Mart. 35. Willd. 21. L'Herit. fert. ang. 26. Hort. Kew. 3. p. 221. Bot. Mag. 406. " Flowers in corymbs; leaves heart-fhaped, angularly toothed, purplifh underneath; petioles winged, eared at the bafe." *Root* perennial. *Stem* herbaceous, two or three feet high. *Flowers* purple. A native of the Canary Iflands, introduced in 1777 by Maffon. 23. C. *cymbalarifolia*, Linn. Amœn. Acad. 6. p. 106. Mart. 2. Lam. 2. " Leaves lyre-fhaped; the end one kidney-fhaped, flightly toothed; upper ftem ones embracing the ftem, lobed, quite entire." *Root* a folid bulb. *Stem* herbaceous, fimple, with an even furface. *Flowers* with a purple ray, peduncled, numerous. There is a variety with fimple trifid leaves, and the lobes trifid. A native of the Cape of Good Hope. 24. C. *angulofa*, Lam. 2. (After Africanus minimus monanthus luteus, Rai. Supp. 16.) " Peduncles fimple; leaves roundifh-angular, petioled; upper ones fomewhat lyrate." *Root* half an inch long, flender, furnifhed with fibres. *Stem* from four to fix inches high, herbaceous, flender, fmooth, branched. *Leaves* fmall, fmooth; petioles almoft capillary, more than an inch long. *Flowers* yellow; peduncles long, fimple, one-flowered; calyx a little pubefcent. A native of the Cape, communicated by Sonnerat to La Marck, who afferts, that it is very diftinct from C. cymbalarifolia, as defcribed by Linnæus in Amœnitates Academicæ. 25. C. *lobata*, Mart. 36. Willd. 23. L'Herit. fert. ang. 26. " Flowers fomewhat in corymbs; leaves roundifh, with many lobes, fmooth; petioles eared at the bafe; calyxes with a few fcales at the bafe." *Root* perennial. A native of the Cape, obferved by Maffon. 26. C. *multiflora*, Willd. 24. L'Herit. fert. ang. 26. " Flowers in cymes; leaves cordate-ovate, tomentous underneath; petioles half-eared. A native of hills in the Canary iflands." *Root* perennial. 27. C. *tuffilaginis*, Willd. 25. L'Herit. fert. ang. 26. " Flowers loofely panicled; leaves kidney-heart-fhaped, with many angles, tomentous underneath; petioles eared at the bafe." *Root* annual. A native of Teneriffe. 28. C. *præcox*, Willd. 26. Cav. Ic. 3. tab. 244. " Flowers in corymbs; leaves heart-fhaped, lobe-toothed, acuminate, fmooth; petioles naked; ftem flefhy." *Root* perennial. *Stem* three or four feet high, about the thicknefs of the human finger. *Leaves* with five or fix deep teeth on each fide, fmooth on both fides. *Flowers* yellow; ray with five florets. A native of Mexico. 29. C. *malvæfolia*, Mart. 34. Willd. 27. L'Herit. fert. ang. 26. " Flowers in cymes; leaves heart-fhaped, angular, a little tomentous underneath: petioles fimple." A native of the Canary iflands, and St. Michael, one of the Azores, introduced by Maffon in 1777. 30. C. *glabra*, Mart. 39. Willd. 28. Swartz. Prod. 113. " Flowers in corymbs; calyxes cylindrical; leaves oblong, acute, a little toothed, nervelefs, fmooth on both fides, fomewhat fucculent; ftem fhrubby." *Root* perennial. A native of Jamaica. 31. C. *difcolor*, Mart. 40. Willd. 28. Swartz. Prod. 113. " Flowers in corymbs; leaves oblong-lanceolate, acuminate, with a few fmall teeth, fmooth, fnowy-tomentous underneath; ftem fhrubby." *Root* perennial. A native of Jamaica. 32. C. *coronata*, Willd. 30. Thunb. Prod. 154. " Leaves inverfely egg-fhaped, crenate, fmooth; flowers terminal; ftem a little fhrubby." *Root* perennial. A native of the Cape of Good Hope. 33. C. *fibirica*, Linn. Sp. Pl. 3. Mart. 3. Lam. 3. Willd. 31. (Jacobæa orientalis, cacaliæ folio; Tourn. Cor. 57. Jacobæaftrum Amm. ruth. tab. 24. Jacobæides uni-crenato folio; Vaill. Act. 1720. p. 300. Solidago n. 139. Gmel. Sib. 2. p. 169.) " Raceme fimple; leaves heart-fhaped, obtufe, finely toothed, with an even furface; ftem quite fimple, one-leafed." Linn. " Flowers in racemes; leaves heart-halbert-fhaped, toothed, fmooth; petioles dilated at the bafe, fheathing." Lam. *Root* perennial. *Stem* a foot and half high, or more, fmooth. *Leaves* with a very fhort point. *Flowers* yellow, in an upright raceme; bractes two at the bafe of the calyx, oblong, the length of the calyx, withering. A native of Siberia, the Levant, and the Pyrenees. 34. C. *glauca*, Linn. Sp. Pl. 4. Mart. 4. Lam. 5. Willd. 32. (Solidago, Gmel. Sib. 2. tab. 74.) " Raceme fimple; leaves fpatulate-heart-fhaped, quite entire, with an even furface; ftem quite fimple." *Root* perennial. *Stem* from three to five feet high, hollow, ftriated. *Leaves* a little flefhy, glaucous; lower ones on enlarged bordered petioles, which embrace the ftem at their bafe. A native of Siberia. 35. C. *paluftris*, Linn. 6. Mart. 10. Lam. 7. Willd. 33. Flor. dan. tab. 573. Eng. bot. 151. (Conyza aquatia laciniata, Bauh. Pin. 266. After paluftris, laciniatus, luteus; Tourn. 483. Othonna paluftris; Linn. it. fcan. fl. fuecica. Solidago, Gmel. Sib. 2. tab. 72.) Marfh. Fleawort. " Flowers in corymbs; leaves broad-lanceolate, tooth-finuated; ftem villous." *Root* perennial, fibrous. *Stems* three feet high, erect, fimple, thick, angular, abundantly leafy. *Leaves* alternate, embracing the ftem, nerved, pale, hairy, often pinnatifid-laciniated, and undulated. *Flowers* bright yellow, with a lemon-coloured ray, numerous; corymbs terminal; peduncles hairy; calyx cylindrical, hairy, yellowifh, not fwelling at the bafe; leaves membranous at the edge; florets of the ray about the fame number as the leaves of the calyx, and a little longer, fomewhat elliptical, toothed at the tip, fpreading; of the difk numerous. *Seeds* furrowed, fmooth; down fcabrous, (filky, Lam.) *Receptacle* pitted. All the hairs of the plant are tranfparent, and finely jointed like a conferva. A native of marfhy ground in England and other parts of Europe, but rare in England. 36. C. *cordifolia*, Linn. jun. Sup. 373. Mart. 6. Lam. 4. Willd. 39. Jacq. Auft. tab. 176, 177. (C. alpina, α, Linn. Sp. Pl. 7. Senecio, Hall. Helv. 63. Jacobæa alpina foliis fubrotundis ferratis, Bauh. Pin. 131. Prod. 70. tab. 69.) " Flowers in panicled corymbs; leaves heart-fhaped, unequally toothed, petioled, pubefcent underneath." Lam. " Panicle few-flowered; ftem fimple; all the leaves petioled, heart-fhaped, doubly toothed; petioles fomewhat toothed at the bafe." Willd. *Root* perennial. *Stem* about a foot high, ftriated, leafy, fimple, or a little branched near the top. *Flowers* yellow; peduncles branched, woolly, furnifhed with fmall fcales; calyx fhort, many-leaved, villous, open. A native of Swifferland and Auftria. Senecio alpinus of the younger Linnæus, (C. alpina, Willd. 40.) has been fuppofed to be C. alpina α of his father: but we think without foundation. The fphacelated tips of the calyx-leaves would furely have prevented Linnæus from making it a cineraria. 37. C. *integrifolia*, Murray, Syft. Veg. 765. Mart. 8. Willd. 37. Jacq. Fl. Auft. tab. 180. Eng. Bot. 152. (C. alpina, γ. Linn. Sp. Pl. 7. C. alpina, Lam. 9. C. campeftris, Willd. 34. Retz. Prod. Flor. Scand. Ed. 2. n. 1027. Hoft, Synop. 464. Jacobæa montana lanuginofa anguftifolia non laciniata, Bauh. Pin. 131. Tourn. 486. Jacobæa pannonica, folio non laciniato, Rai. Syn. 178. Bauh. Hift. vol. ii. 1056.) β. C. alpina, Allion. Ped. vol. i. tab. 38. fig. 2. (C. aurantiaca, Willd. 35. Hoppe Ant. pl. 4.) " Leaves oblong,

long, obsoletely toothed, villous; umbel simple, involucred." Dr. Smith. "Peduncles simple, umbellate; stem-leaves oblong, entire, sessile; root ones egg-shaped, somewhat toothed, lessening into the petiole; stem simple." Lam. "Flowers umbellate; stem simple; leaves tomentous; root-ones egg-shaped, somewhat crenulate; stem-ones lanceolate, quite entire." Willd. *Root* perennial, fibrous. Whole herb cloathed with a white deciduous down. *Stem* about two feet high, furrowed. *Leaves* somewhat revolute; root-ones depressed, larger, and more obtuse; stem-ones alternate, erect, narrower. *Flowers* of a bright gold-colour, in a terminal umbel with few flowers; each peduncle furnished with a short lanceolate bracte at its base; calyx cylindric-hemispherical, smooth; leaves woolly at the base, with a membranous margin; florets of the ray numerous, twice the length of the calyx, elliptic oblong, three-toothed at the tip, spreading. *Seeds* with silky hairs; down scabrous. Stem in β a foot high; all the leaves, especially the stem-ones, larger, more naked on the upper surface; root-ones sometimes with broad teeth. A native of England, Sweden, Austria, France, and Siberia. 38. C. *longifolia*, Murray, Syst. Veg. p. 765. Mart. 9. Willd. 33. Jacq. Flor. Aust. tab. 181. (C. alpina, δ. helenites, Linn. Sp. Pl. 7. Othona, Sp. Pl. Ed. 1. Jacobæa montana polyanthos, Barr. Ic. 226.) "Leaves with five obsolete teeth; all oblong," Mur. "Flowers umbellate-corymbous; stem simple; leaves somewhat toothed; root-ones spatula-shaped; stem-ones oblong-lanceolate. Willd. *Root* biennial. It varies in having the leaves either quite entire, or toothed, smooth or villous. A native of subalpine woods in Thuringia, Austria, Italy, and France. The integrifolia of Murray and Willdenow, to which, however, the latter attributes a perennial root, Jacquin's tab. 179, seems to be only a variety of this species, with the lower stem-leaves, as well as the root-one spatula-shaped; whereas, in C. longifolia, all the stem-leaves are oblong lanceolate. 39. C. *crispa*, Linn. Supp. 376. Mart. 7. Willd. 38. Jacq. Aust. tab. 178. "Flowers umbellate-corymbous; stem simple; leaves toothed; lower ones spatulate-heart-shaped; with winged, finely toothed petioles; upper ones sessile, lanceolate." Willd. *Root* perennial. *Stem* two feet high, erect, furrowed. *Leaves* curled, and waved about the edge; root-ones heart-shaped; stem-ones a little embracing the stem; peduncles and calyxes villous. A native of Austria. 40. C. *aurea*, Linn. Sp. Pl. 8. Mart. 11. Lam. 8. Willd. 41. "Flowers in corymbs; leaves lanceolate, serrated, tomentous underneath." Linn. *Root* perennial. *Stem* villous. *Leaves* slight, villous on the upper surface. *Flowers* yellow, large, with an ample ray; pedicels with a few linear bractes. A native of Siberia. 41. C. *Japonica*, Murray, Syst. Veg. 766. Mart. 26. 41. Willd. 42, Thunb. jap. 317. "Leaves sword-shaped, toothed, tomentous; flowers terminal." *Stem* cylindrical, simple, erect, tomentose. *Leaves* alternate, acute, lessened at both ends, woolly, erect. *Flowers* yellow, solitary, or by threes; calyx woolly. A native of Japan. 42. C. *maritima*, Linn. Sp. Pl. 9. Mart. 12. Lam. 10. Willd. 43. (Jacobæa maritima, Bauh. Pin. 431. Tour. 486.) "Flowers panicled; leaves pinnatifid, tomentous; segments sinuated; stem shrubby." Linn. *Root* perennial. The whole plant remarkable for a very white cottony down, which covers the stem, peduncles, calyxes, petioles, and the under side of the leaves. *Stems* several, two or three feet high, hard, and sometimes continuing through the winter, but not properly woody, cylindrical, leafy, branched. *Leaves* soft; lower ones petioled, egg-shaped, slightly pinnatifid, greenish on the upper surface. *Flowers* yellow, in terminal panicles, on the stem and branches; florets of the ray revolute. A native of the sea-coast of Languedoc and Provence, Italy, and the Levant. It is one of the most specious of the genus, and merits cultivation on account of its beauty. 43. C. *bicolor*, Willd. 44. "Flowers in corymbs; calyxes greyish, pubescent; leaves oblong, pinnatifid at the base, shining, and smooth above, downy underneath; segments somewhat toothed; stem shrubby." It seems only a variety of the preceding species, differing from it in being less woolly. Described by Willdenow from a living plant, but probably the effect of cultivation, as its native country is unknown. 44. C. *canadensis*, Linn. Sp. Pl. 10. Mart. 13. Willd. 45. (Jacobæa maritima, s. cinerea latifolia, Bauh. Pin. 131.) "Flowers panicled; leaves pinnatifid, somewhat villous; segments sinuated; stem herbaceous." Linnæus states this to be the daughter of C. *maritima*; but differing in the leaves not being tomentous, but only somewhat villous, especially underneath; in the ray of the corolla being spreading, not revolute; in the stem being annual, not perennial; and in the calyx being slightly sphacelated at the tip, which it is not in C. *maritima*. A native of Canada. 45. C. *balsamita*, Lam. 11. (Jacobæa orientalis, foliis oblongis non laciniatis incanis, Tourn. Cor. 36.) "Leaves petioled, egg-shaped, crenate-serrated, tomentous; corymb small, compound." *Stem* a foot high, angular, woolly, quite simple, leafy. *Leaves* narrowed into the petiole at the base, cottony, and whitish. A native of the Levant. Specimen preserved in the herbarium of Jussieu. 46. C. *aspera*, Willd. 46. Thunb. Prod. 153. "Leaves linear, pinnated, toothed, tomentous underneath; flowers panicled." A native of the Cape of Good Hope. 47. C. *capillacea*, Linn. jun. Supp. 375. Mart. 14. Willd. 47. "Leaves pinnated; pinnæ capillary, entire." Very like *othonna tagetes*, but its leaves are deeply divided and more slender. 48. C. *minuta*, Mart. 38. Willd. 48. Cav. Icon. i. tab. 33. fig. 3. (Bellis minima, Barr. Ic. 1153. fig. 1.) "Peduncles one flowered; root-leaves smooth, wedge-shaped, with about five teeth; stem-ones pinnated, linear-filiform, hairy; stem hairy." *Root* annual. *Stems* sometimes two or three, two or three inches high, simple, one-flowered beset with long slender hairs. *Root leaves* petioled; stem-ones sessile. *Flower* white. A native of mountainous ground in Spain. 49. C. *linifolia*, Linn. Sp. Pl. 11. Mart. 15. Lam. 14. Willd. 49. Jacq. Hort. Schoen. 3. tab. 308. "Peduncles one-flowered; leaves scattered; stem shrubby." Linn. "Peduncles one-flowered; axillary; leaves linear-awl-shaped, smooth; stem shrubby." Willd. It differs from *senecio linifolia*, in having all the flowers solitary. *Stem* compound, rough. *Flowers* yellow small; peduncles longer than the leaves. A native of the Cape of Good Hope. 50. C. *humifusa*, Mart. 30. Willd. 50. L'Herit. Sert. Ang. 25. (C. pumila, Thunb. Prod. 155.) "Peduncles one-flowered; leaves kidney-shaped, somewhat angular; petioles sometimes eared, sometimes naked at the base." *Root* perennial. A native of the Cape. 51. C. *viscosa*, Mart. 31. Willd. 51. L'Herit. Sert. Ang. 25. Jacq. Frag. 12. tab. 7. fig. 2. (C. pandurata, Thunb.?) "Peduncles one-flowered; leaves pinnatifid-lobed, acute, viscid, somewhat fleshy. *Root* biennial. A native of the Cape. 52. C. *purpurata*, Linn. Mant. 285. Mart. 16. Lam. 16. Willd. 52. "Stem with about two flowers; leaves inversely egg-shaped, somewhat tomentous." *Root* perennial. *Stem* a foot high, herbaceous, simple, furrowed near the bottom. *Leaves* alternate, petioled, obtuse, pubescent above, cottony underneath. *Flowers* with a purple ray; peduncles terminal, as long as the stem, filiform, cottony, erect, one-flowered; calyx-leaves lanceolate, nearly equal,

equal, ſhort, pubeſcent; down feathered. *Receptacle* naked. A native of the Cape. 53. C. *amelloides*, Linn. Sp. Pl. 13. Mart. 17. Lam. 17. Willd. 52. Bot. Mag. 249. (Solidago africana fruteſcens cærulea, hyperici foliis plerumque conjugatis. After africanus fruteſcens, Rai. Supp. 158.) "Peduncles one-flowered; leaves oppoſite, egg-ſhaped, naked; ſtem ſomewhat ſhrubby." *Root* perennial. *Stem* two feet high, purpliſh, rough, dividing into many branches near the root, ſo as to form a low buſhy plant. *Leaves* about an inch long, and a third of an inch broad, thick, ſucculent, ſeſſile, generally two, but ſometimes three or four at a joint. *Flowers* with a yellow diſk and ſky-blue ray. Nearly allied to *amellus lychnitis*, but differing in its naked receptacle. A native of the Cape; and a common inhabitant of our green-houſes, where it flowers moſt of the year. The ſeeds were ſent to Miller in 1753. 54. C. *lanata*, Mart. 29. Lam. 12. Willd. 54. L'Herit. Sert. Ang. 25. Jacq. Collect. iii. tab. 19. fig. 3. Bot. Mag. 53. "Peduncles one-flowered; leaves roundiſh-heart-ſhaped, with ſeven angles, downy underneath." L'Herit. "Leaves roundiſh-angular, on long petioles, white, with down underneath; flowers ſolitary, terminal." Lam. *Root* perennial. *Stems* from twelve to ſix inches high, woody at their baſe, feeble, a little branched, cottony, and whitiſh near the top. *Leaves* alternate, green on their upper ſurface, white and cottony underneath. *Florets* of the ray of a viſcid purple upwards, white near the bottom; calyx cylindrical, ſmooth. A native of the Canary iſlands; introduced by Maſſon in 1780. 55. C. *ſcapiflora*, Willd. 53. L'Herit. Sert. Ang. 25. "Peduncles very long, one-flowered; leaves egg-ſhaped, ſmooth, doubly-toothed." A native of the Cape of Good Hope. 56. C. *laricifolia*, Lam. 15. (Jacobæa Breyn. Cent. tab. 64. Moriſ. Hiſt. 3. tab. 18. fig. 31.) "Flowers erect, lateral and terminal; little branches ſhort, one-flowered; leaves ſcattered, crowded, linear-awl-ſhaped, keeled; ſtem ſhrubby." A ſhrub, ſcarcely a foot high, ſmooth in all its parts. *Stem* cylindrical, with ſlender branches, leafy on its upper part, naked and marked with the ſcars of fallen leaves near the bottom. *Leaves* channelled on their upper ſurface, ſcarcely an inch long. *Flowers* yellow, ſeſſile; florets of the ray few, diſtant from each other; calyx ſimple, but apparently compoſed of two ranks, occaſioned by the preſſure of the upper leaves of the branches. A native of the Cape of Good Hope, communicated by Sonnerat. 57. C. *chamædrifolia*, Lam. 20. "Stem herbaceous, angular, naked near the top; leaves petioled, heart-ſhaped, crenate, hoary underneath." *Stem* from ſix to eight inches high, zig-zag near the baſe; branches two or three near the top, one-flowered, furniſhed with ſmall acute ſcales. *Leaves* ſmall, ſmooth on both ſides, but greyiſh underneath. *Flowers* terminal; calyx ſimple, ſmooth, many-leaved. A native of the Cape. 58. C. *anthemoides*. Lam. 21. "Leaves ſeſſile, deeply pinnatifid; lobes lanceolate-toothed, ſlender; ſtem herbaceous." *Stem* eight or nine inches high, ſtriated, branched, leafy. *Leaves* greeniſh, beſet with a few hairs. *Flowers* yellow; peduncles one-flowered, ſmooth, furniſhed with very ſhort acute ſcales; calyx ſmooth, quite ſimple. 59. C. *haſtifolia*, Lam. 24. Mart. 25. Linn. jun. Suppl. 376. "Leaves halberd-ſhaped; ſegments lateral, bifid, divaricated." *Stem* ſeven inches high, erect. *Leaves* alternate, petioled. *Flowers* yellow; peduncles elongated, furniſhed with awl-ſhaped ſcales; calyx with about ten leaves.

Obſ. According to Juſſieu, C. amelloides recedes from the reſt of the genus, on account of its purple flowers and oppoſite leaves, but neither of theſe can be allowed to form part of a generic character, and if they did, ſeveral other ſpecies muſt be removed. Gærtner has ſeparated C. glauca and C. purpurata, on account of their feathered down, and placed them in a new genus which he calls ſeneciliis, but it may alſo be doubted whether this be of itſelf a ſufficient generic difference. Thoſe ſpecies which have a few ſcales at the baſe of the calyx ſeem more allied to ſenecio, wanting only the ſphacelated tips of the calyx-leaves, and ſhewing, as La Marck obſerves, that there is no ſolid diſtinction between the two genera. As the ſpecies of ſenecio are very numerous, it might facilitate the ſtudies of the young botaniſt, if theſe were formed into a new genus, of which the preſence of the ſcales and the abſence of the ſphacelated tips ſhould form the eſſential character. Or it would anſwer the ſame purpoſe if the whole were thrown into one genus, divided into three ſections. The chief objection is the difficulty of finding trivial names.

C. *othonnites*, Linn. See OTHONNA *fruteſcens*.

— *abrotanifolia*, Berg. See OTHONNA *abrotanifolia*.

Propagation and Culture. Many of the ſpecies are well-known ornaments to our green-houſes, and others are worthy of being introduced. Moſt of them may be increaſed by cuttings, planted in a ſhady border, during the ſummer months, and duly watered. In a month or five weeks they ſhould be tranſplanted into pots, to prevent their roots from ſpreading. But they are too tender to endure the open air in the winter of our climate. C. maritima is hardier, and if the ſlips be planted in a dry rubbiſhy ſoil, they will live out of doors all the winter, and thrive many years; but in rich ground the plants are ſo luxuriant in ſummer as to be killed by the froſt in winter. C. amelloides, and ſome of the others, may alſo be propagated by ſeeds, ſown on a bed of light earth in the beginning of April. When the plants are fit to remove, part of them ſhould be planted in pots, to be ſheltered in winter under a hot-bed frame, and the remainder under a wall in poor ground, where, if the winter prove favourable, they will live. Miller. C. lunata, lately introduced into this country, which far exeeds all others cultivated here, in the beauty of its flower, is a valuable acquiſition to the green-houſe, alſo on account of its hardineſs, its readineſs to flower, and the facility with which it may be propagated. It flowers early in the ſpring, and may be made to continue nearly the whole year. It is particularly liable to be infeſted with aphides, or in the language of gardeners, to become louſy. The only method to have healthy plants is, to procure a conſtant ſucceſſion by cuttings. Theſe ſhould be placed in a pot, and plunged into a bed of tan. Curtis Bot. Mag.

CINERARIUS, in *Antiquity*, an officer retained by the women, whoſe buſineſs it was to provide aſhes proper for tinging the hair with a deep yellow colour. He was otherwiſe called *ciniflo*.

CINERARIUS is alſo uſed to ſignify one who paid a veneration to the relics of martyrs and ſaints.

CINERATION, in *Chemiſtry*, the reduction of wood, or any other combuſtible matter, into aſhes, by means of fire. This, others call *cinefaction*.

CINERES. See ASHES.

CINERES *clavellati*, in *Chemiſtry*, or *Pearlaſh*, is a conſiderably pure ſub-carbonat of Potaſh, which ſee.

CINERES *Ætnæ*, a name given by authors to a duſty and ſaline ſubſtance thrown out of mount Ætna, in form of powder, and reſembling aſhes. After an eruption of this mountain, theſe ſaline aſhes are found ſcattered about the opening itſelf, down the ſides of the mountain, and over the country for ten miles or more round. Thoſe aſhes, which are found thrown to the diſtance of eight or ten miles, are generally taken up in form of a very dry duſt, almoſt inſipid to to the tafte: but what lie upon, and round about the fkirts of the mountain, are very different; they are never dry, though they lie many months expofed to the fun's heat, which is very great there, but always feel damp and wet, and are compofed of larger or fmaller lumps, and not of a fine powder, as the more diftant are. They are of a very ftrongly vitriolic tafte, refembling that of our common green copperas. From this tafte, and from the great quantities of matter refembling a fort of crocus Martis, and with thefe a great abundance of fulphur, which is burnt away, and the vaft quantities which alfo are fublimed about the mouths, and left unburnt, it appears, that the common pyrites is contained in vaft abundance in the bowels of the mountain, fince green vitriol and fulphur are its produce, and nothing is fo eafy as to calcine it with the purple powder refembling crocus Martis, which is the third fubftance fo frequent there. This gives great weight to the opinion of thofe who believe all the eruptions of the burning mountains in the feveral parts of the world to be owing to this mineral. See PYRITES and VOLCANO.

CINERITIOUS, a term applied to things refembling afhes; particularly in point of colour and confiftence.

Thus, the cortical part of the brain is alfo called the *cineritious* part.

CINETTRI or CINITTRI, in *Ancient Geography*, a people of Africa, according to Ptolemy, who inhabited the defert, S.E. of the river Bagradas.

CINEY, in *Geography*. See CHINY.

CINGA, *Cinca*, a river of Hither Spain, which has its fource in the Pyrenées, and running to the fouth, paffed by the territories of the Illergates, in order to difcharge itfelf into the ocean. The inundation of this river, and that of the Sicoris in the plain near Ilerda, proved very injurious to Cæfar, becaufe, by the removal of the bridges, he could not keep up a communication with the town that had joined him. But, in order to effect this purpofe, he engaged all the barks, which he could find along the Iberus.

CINGILIA, a town of Italy, in the country of the Veftini, which was taken by the conful Brutus.

CINGULUM, in *Conchology*, a fpecies of *Conus*, found in the Friendly Iflands.

CINGULUM, in *Geography*, a town of Italy in the Picenum. Cæfar fays that it was built at the expence of Labienus. It is mentioned by Pliny, Cicero, Silius Italicus, and Frontinus. It is now known by the name of *Cingoli* or *Cingolo*.

CINGULUM. See CINCTUS.

CINGULUM *Mundi*, mountains which the ancients alfo called the "Hyperborean mountains." Thefe mountains are probably thofe which the Ruffians call *Ziemnoipoias*.

CINGULUM *Sapientiæ*. See GIRDLE.

CINIFLO, in *Antiquity*, the fame with CINERARIUS.

CINIUM, in *Ancient Geography*, a name given by Pliny to the greater of the Balearic Iflands; the inhabitants of which enjoyed the fame rights with thofe of Latium.

CINNA, LUCIUS CORNELIUS, in *Biography*, an afpiring Roman, who raifed himfelf to the higheft honours of the ftate, by attaching himfelf, during the civil contentions, to the popular faction. In the year of Rome 667, Cinna was elected conful, during the tyranny of Sylla, though he had been the avowed friend of Marius. He had no fooner entered upon his newly acquired office, than he drove Sylla from Rome to his army in Afia. He then attempted to ftrengthen his party by incorporating a number of new citizens into the ancient tribes from the allies. This was oppofed by his colleague Octavius, and the fenators, who yet held the honour of citizenfhip in high eftimation; a bloody battle was fought in the forum between the two parties. Cinna was defeated; he and fix tribunes who had fided with him were expelled the city. They proceeded to depofe him from the confulfhip, and chofe Cornelius Merula in his ftead. Cinna applied for fuccour to the allies, by whom he was furnifhed with money and troops, and, having by his various arts, gained over a large body of Roman foldiers encamped at Capua, he was joined by fuch numbers, that he formed an army of thirty legions. He then invefted Rome, and forced Metellus, in whom the care of defending the capital was lodged, to retire: Merula the new conful refigned his authority, and Cinna was again acknowledged as conful. Not contented with a fimple reftoration to all his honours, he entered Rome with Marius, and the other leaders of his party. At firft, they feemed contented with the deftruction of Octavius, but they afterwards profcribed all thofe who had attained to fenatorial rank, and a great multitude of the nobleft and moft honourable of the Romans were facrificed at the fhrine of their mad ambition. At the expiration of the confular year, Cinna nominated himfelf and Marius confuls for another year. The latter dying foon after the nomination to office, Cinna fhared the authority with the younger Marius, who was no lefs cruel than his father. He made himfelf conful a third time, with Papirius Carbo, and, to ftrengthen his hands, he married his daughter to Julius Cæfar, a man hereafter deftined to act a great part in his country. Intelligence arrived, that Sylla was preparing to return to Rome at the head of a formidable army. Cinna, unwilling that the war fhould be carried on in Italy, determined to meet his rival in Dalmatia; while, however, he was on the point of embarking his troops, a mutiny was excited among them, in which he was flain by his own foldiers, at the port of Ancona, in the year 670. Cinna has been defcribed as one who, having attempted what no good man would have dared, performed what none but a very brave man could have effected.

CINNA, in *Botany*. See AGROSTIS *Cinna*. It is a native of Canada, whence feeds were fent by Kalm.

CINNA, in *Ancient Geography*, a town of Italy, taken, according to Diodorus Siculus, by the Romans from the Samnites.—Alfo, a place of Dalmatia, marked by the Itinerary of Antonine, on the route from Salone to Durazzo, between Birziminium and Scodra.—Alfo, a town of Spain, placed by Ptolemy in Juetania, a country of the Tarragonenfis.—Alfo, a town of Afia, in Perfia Propria, according to Ptolemy.

CINNABAR. See MERCURY.

CINNAMOLOGUS, in *Natural Hiftory*, among the ancients, the name given to a bird which built its neft either in the cinnamon-tree, or upon rocks and precipices, with the broken branches of that tree. The ancients have a great many idle traditions concerning this bird: fome fay it is the phœnix; and others, that it is a peculiar fpecies of fowl. The common opinion of the phœnix building its neft of fpices feems to have given birth to all the idle ftories that we hear of this bird in Pliny, and other credulous authors.

CINNAMOMIFERA REGIO, in *Ancient Geography*, the name of a country of Ethiopia, near Egypt, according to Ptolemy and Strabo. The latter places this country at the commencement of the Torrid Zone, and fays, that Sefoftris, king of Egypt, penetrated fo far.

CINNAMON, in *Botany*. See LAURUS *Cinnamomum*.

CINNAMON. *Cinnamomum*, in the *Materia Medica*. The bark of the cinnamon tree (*Laurus cinnamomum*, Linn.), is the part ufed in medicine It is of a brown red colour, light and thin, and rolled up in long brittle quills. The fmell ſmell is delightfully fragrant, and the taſte is highly pungent and aromatic, with a conſiderable ſweetneſs, and ſome aſtringency. The thinneſt pieces are by much the moſt aromatic. Cinnamon, infuſed in boiling water, in a covered veſſel, gives out much of its grateful aromatic flavour, and forms an agreeable reddiſh-brown infuſion. Alcohol, ſtrong or diluted, extracts the aromatic part more completely, and without artificial heat. The aroma of the cinnamon reſides in an eſſential oil, which is extracted by diſtillation with water, though with ſome difficulty. Oil of cinnamon has a clear golden yellow colour, and a moſt powerfully fragrant ſmell. The taſte is exceſſively fiery, and abſolutely cauſtic, corroding the ſkin very ſpeedily. This oil is heavier than water. It is altogether prepared in Ceylon, and imported. When cinnamon is diſtilled with water juſt ſufficient to cover it in the ſtill, the diſtilled water that comes over is milky and turbid, and has a mild and agreeable flavour of the ſpice. If a large quantity is prepared at once, a few drops of oil collect at the bottom of the water. From a pound of cinnamon about a gallon of ſtrong diſtilled water may be prepared. The watery decoction remaining in the ſtill, yields, on evaporation, a red extract, of a mucilaginous and gently aſtringent taſte, but without any thing aromatic.

Pure alcohol, diſtilled from cinnamon, brings over very little of its flavour; ſo that if an extract is made with this menſtruum, it retains moſt of the rich aroma and pungency of the cinnamon. Proof ſpirit, on the other hand, when diſtilled from this bark, gives a clear, ſtrong, aromatic, ſpirituous water. This, as well as the ſimple water, is much uſed in medicine.

Cinnamon is one of the moſt grateful aromatics that we poſſeſs, and is employed as a cordial, reſtorative, and for all the purpoſes for which aromatics are uſeful. It is ſeldom, if ever, given alone; for the aromatics, though their ſenſible qualities are ſo decided, have but a temporary and uncertain effect on the conſtitution, and contribute but little to the cure of important diſeaſes. But, as an auxiliary in a variety of ways, and to cover the flavour of nauſeous medicines, cinnamon is eminently uſeful, and enters into the compoſition of a vaſt variety of tinctures, confections, cordial mixtures, and the like. A drop of the oil, dropped on a lump of ſugar, is one of the readieſt and moſt powerful ſtimulants in faintings and ſudden debility.

On account of the high price of the cinnamon, the *caſſia* bark, which much reſembles it, is very generally ſubſtituted. The general appearance, ſmell, and flavour, of the two are the ſame, only the aromatic property is much weaker, and it wants much of the grateful ſweetneſs of the real cinnamon. The caſſia may be diſtinguiſhed by the ſmooth ſurface which it exhibits when broken, and by its ſlimy taſte.

This ſubſtitution, though a real inconvenience, in many caſes is of little conſequence in preparing the diſtilled water; for water diſſolves ſo little of the eſſential oil, that, in the uſual proportions, it appears to ſaturate itſelf from the caſſia as completely as from the real cinnamon.

CINNAMON, *clove*, is alſo the bark of a tree growing in Braſil and Madagaſcar; where it is known under the name of *ravendſara*. The Portugueſe call it *cravo de marenham*.

This bark, pulveriſed, is ſometimes ſubſtituted for real cloves, though far ſhort of them in reſpect of flavour.

Saſſafras is ſometimes alſo called *cinnamon-wood*. See SASSAFRAS.

CINNAMON, *white*, which ſome call *coſtus corticus*, or *corticoſus*, or erroneouſly *cortex Winteri*, *Winter's bark*, from the perſon's name who firſt brought it into England, is the bark of a tree, reſembling the olive-tree, frequent in the iſlands of St. Domingo, Guadaloupe, and Madagaſcar; called by the natives *ſimpli*.

This bark, which dries like that of cinnamon, is at firſt browniſh, of a ſharp biting taſte, like pepper, and a ſmell like muſk; as it dries it whitens. Some uſe it in lieu of nutmeg; and in medicine it is uſed as a ſtomachic, and ſometimes as an antiſcorbutic.

The ſame tree alſo yields a gum called *alouch*, ſometimes *bdellium*, which is no diſagreeable perfume. See *Winteranus* CORTEX and WINTERANIA.

CINNAMUM, the name given by many of the old writers on the materia medica to cinnamon. The Arabian writers, when they treat of cinnamon, have three words by which they expreſs it; theſe are *ſelicha*, *daſini*, and *kanſe*.

CINNAMUS, JOHN, in *Biography*, a Greek, who flouriſhed in the 12th century. In his youth he followed the profeſſion of arms, and was preſent at various expeditions in Europe and the Eaſt. After the death of Manuel, he compoſed hiſtories of John Comnenus, and Manuel, his ſon, comprehending their actions from 1118 to 1176. He is characterized by Leo Allatius as an elegant author, who frequently uſes foreign forms of expreſſion, and figures from the ſchools, whence he ſometimes falls into obſcurity. According to Voſſius, his diction is more pure and terſe than that of the modern Greeks in general; and he is an imitator of Xenophon. His hiſtory was firſt printed in Greek and Latin, with notes, at Utrecht, 1652, in 4to. Another edition has been ſince publiſhed in folio by Du Cange, at Paris, with hiſtorical and philological obſervations.

CINNERETH, or KINNERETH, *ſea and lake of*, in *Ancient Geography*, otherwiſe called the lake or water of Geneſareth. See *Sea* of GALILEE.

CINNIANA, or CIRANIA, now *Sitania*, a town of Spain, in Luſitania. Valerius Maximus informs us, that when D. Brutus expreſſed his deſire that the inhabitants ſhould ranſom their city, they returned him anſwer, that they had iron to defend it, but no gold to ranſom it.

CINNORUM *Civitas*, an epiſcopal town of Aſia, in Galatia prima.

CINNUS, in *Ancient Medicine*, a drink made of the decoction of wheat, to which was added ſome flour of barley, honey, and wine.

CINO DU PISTOIA, in *Biography*, ſo called from his native place, but by his family name De' Sigibuldi, an eminent lawyer and poet, flouriſhed in the beginning of the 14th century. He ſtudied law at Padua and Bologna, but with ſo little application or ſucceſs that he was at firſt refuſed the degree. This circumſtance had its proper effect in rouſing his diligence, and he ſoon attained to great profeſſional reputation. He was made principal aſſeſſor to Lewis of Savoy, when ſenator of Rome, to which office he was choſen in 1310. In 1314 he finiſhed a voluminous commentary on the code, and obtained a doctor's degree at Bologna. He was profeſſor at various univerſities, and was intimate with many diſtinguiſhed characters, among whom was Petrarch, who lamented his death in a ſonnet. Beſides the commentary on the code, printed at Frankfort in 1578, Cino commented on ſome parts of the Digeſt. But he derived the greater part of his reputation from his poetical works. By general ſuffrage he is placed among the moſt cultivated Italian poets of the age in which he flouriſhed; and of thoſe who preceded Petrarch, not one is to be compared to him for elegance and ſweetneſs. The moſt complete edition of his works is that of Venice in 1589.

CINOLIS, in *Ancient Geography*, or *Cimolis* of Strabo, a town

town of Aſia, in Galatia. Arrian ſays that it was a commercial and maritime town, at the diſtance of 60 ſtadia from Egineta, and 180 from Stephana. Others repreſent it as a village having a river and harbour.

CINQUAIN, in *Ancient Military Language*, an order of battle compoſed of five battalions or five ſquadrons. To form the cinquain, place the five battalions or five ſquadrons in one line, then make the ſecond and fourth advance to form the van, or *avant garde;* leave the firſt and fifth on the original line or ground as the main body, or *corps de bataille;* and make the third or middle one fall back to form the rear or *arriere-garde.* When the number of regiments or ſquadrons is equal to a multiple of five by any whole number n, or is equal to $5\,n$, they may be formed into the ſame order of battle.

CINQUEFOIL, in *Botany*. See POTENTILLA.

CINQUEFOIL, *baſtard*. See SIBBALDIA *procumbens*.

CINQUEFOIL, *marſh*. See COMARUM *paluſtre*.

CINQUEFOIL is a term in *Heraldry*, to repreſent a leaf of graſs of five points.

CINQUEFOIL *root*, in the *Materia Medica*, the name of a root which uſed to be an ingredient in ſeveral of the officinal compoſitions. The plant which produces it is the common cinquefoil, which grows every where by way-ſides. The root conſiſts of a cortical and ligneous or ſticky part, but the cortical only is uſed. It is eſteemed drying, and aſtringent, and antifebrific. Some have given it in agues in as large doſes as the cortex, and have cured with it. It ſtops fluxes of the bowels, and is good in diſorders of the lungs, and in the *fluor albus* and gonorrhœas, either in men or women. It is, however, very little regarded in the preſent practice. See Phil. Tranſ. vol. xlix. part ii. p. 835.

CINQUEL, in *Geography*, a town of the iſland of Sumatra, on the weſtern coaſt of a river of the ſame name.

CINQUE-MARS, in *Geography*, a town of France, in the department of the Indre and Loire, 10 miles N.W. of Tours.

CINQUE-PORTS, *Quinque portus*, five havens that lie on the eaſt part of England, towards France, thus called by way of eminence, on account of their ſuperior importance, as having been thought by our kings to merit a particular regard, for their preſervation againſt invaſions.

Hence they have a particular policy, and are governed by a keeper, with the title of lord warden of the cinque-ports, which office belongs to the conſtable of Dover; and their repreſentatives are called barons of the Cinque-ports.

They have various franchiſes ſimilar in many reſpects to thoſe of the Counties Palatine, and particularly an excluſive juriſdiction before the mayor and jurats of the ports; their warden having the authority of an admiral among them, and ſending out writs in his own name; and the king's writs do not run there. However, on a judgment in any of the king's courts, if the defendant hath no goods, &c. except in the ports, the plaintiff may get the records certified into chancery, and from thence ſent by *mittimus* to the lord-warden to make execution. 4 Inſt. 223. 3 Leon. 3.

Camden tells us, that William the Conqueror firſt appointed a warden of the Cinque-ports; but king John firſt granted them their privileges; and that upon condition that they ſhould provide eighty ſhips at their own charge for forty days, as often as the king ſhould have occaſion in the wars; he being then ſtreightened for a navy to recover Normandy.

There are alſo ſeveral towns adjoining, to which the privileges of the Cinque-ports extend.

There are ſeveral courts belonging to theſe ports; one before the lord-warden; others within the ports themſelves before the mayor and jurats; another, which is called *curia quinque portuum apud Shepway;* a writ of error lies from the mayor and jurats of each port to the lord-warden in his court of Shepway; and in theſe caſes the mayor and jurats may be fined, and the mayor removed, &c. (4 Inſt. 334. Crompt. Juriſd. 138.) and alſo from this court to the king's bench: and a writ of error lies from all the other juriſdictions to the ſame ſupreme court of judicature, in token of the ſuperiority of the crown when theſe franchiſes were created. All prerogative writs, as thoſe of *habeas corpus*, prohibition, *certiorari*, and *mandamus*, may likewiſe iſſue to all theſe juriſdictions; becauſe the privilege, that the king's writ runs not, muſt be intended between party and party, for there can be no ſuch privilege againſt the king. They have likewiſe a court of chancery, to decide matters of equity; but no original writ iſſues thence.

The Cinque-ports, it has been obſerved, are not "*jura æqualia*," like counties palatine, but are parcel of the county of Kent; ſo that if a writ be brought againſt one for land within the Cinque-ports, and he appears, and pleads to it, and judgment is given againſt him in the common pleas, this judgment ſhall bind him; for the land is not exempted out of the county, and the tenant may waive the benefit of his privilege. Wood's Inſt. 519.

Theſe five ports are Dover, Haſtings, Romney, Hythe, and Sandwich; to which Winchelſea and Rye have been ſince added. Thorn tells us, that Haſtings provided twenty one veſſels, and in each veſſel twenty-one men. To this port belong Seaford, Pevenſey, Hedney, Winchelſea, Rye, Hamine, Wakeſbourn, Creneth, and Forthclipe.—Romney provided five ſhips, and in each twenty-four men. To this belong Bromhal, Lyde, Oſwarſtone, Dangemares, and Romenhal.—Hythe furniſhed five ſhips, and in each twenty-one ſeamen. To this belongs Weſtmeath.—Dover, t[illegible] number as Haſtings. To this belong Folkſto[illegible], F[illegible]ſham, and Marge.—Laſtly, Sandwich furniſhed the [illegible] with Hythe. To this belong Fordiwic, Reculver, Serre, and Deal.

CINQUE-PORT *net*. See NET.

CINQUE-VILLAS, in *Geography* a town of Portugal, in the province of Beira; 2 leagues N.E. of Almeida.

CINQ-MARS, HENRY COIFFIER, *Marquis of*, in *Biography*, born in 1620, was introduced by Richlieu to Louis XIII. for the purpoſe of becoming his favourite, a poſt for which he was well qualified, having an agreeable perſon, and being endowed with ready talents for converſation. He was ſoon promoted to high honours, and the cardinal hoped to have reaped advantage from him whoſe fortune he had made; but in this he was completely diſappointed. Cinq-Mars was ambitious only of his own elevation, and deſtitute of every principle of gratitude; he even thwarted the views of Richlieu, and gladly complied with the king's deſire of being preſent at all the private conferences with the cardinal. This was not agreeable to the miniſter, and he gave his eléve a ſevere lecture on his preſumption for interfering in ſtate affairs, and forbade him from attending at any future councils. He alſo mortified his pride and vanity by queſtioning his pretenſions to a marriage with the princeſs Mary de Gonzaga, afterwards the wife of the king of Poland. On theſe accounts Cinq-Mars reſolved to revenge himſelf on his benefactor, and excited the king's brother, Gaſton, duke of Orleans, to a revolt, in which the duke de Bouillon participated. A treaty was made with Spain in Gaſton's name, by which it was agreed to lay open France to her enemies. In the mean time Cinq-Mars did not fail, at every opportunity, to declaim againſt the cardinal, and urged the king to baniſh him from his court, and to get him aſſaſſinated. The king appeared to reliſh the propoſals. Richlieu, though confined by illnefs, was too penetrating not to difcover his approaching difgrace. Fortunately, at this juncture, he made the difcovery of the treafonable negotiation carried on by the faction with Spain, and immediately informed the king of it. Cinq-Mars was arrefted, and carried to Lyons for trial. Gafton, to make his own peace, furnifhed abundant evidence for the conviction of the late favourite. Cinq-Mars was capitally condemned, together with his friend De Thou, fon of the celebrated hiftorian and prefident, and was beheaded in September 1642, in the 22d year of his age. Gen. Biog.

CINTEGABELLE, in *Geography*, a town of France, in the department of the Upper Garonne, and chief place of a canton, in the diftrict of Muret, feated on the Arriege; 16 miles S. of Touloufe. The place contains 2984, and the canton 8695 inhabitants: the territory includes 195 kiliometres and 8 communes.

CINTRA, a town of Portugal in Eftramadura, feated between the mountains of Cintra, near the mouth of the Tagus, and diftant 4 leagues from Lifbon. The houfes lie difperfed in a picturefque manner over the declivity of the mountain; it has a royal caftle, formerly the refidence of feveral kings; it is faid to have been built by the Moors, and after having been deftroyed by an earthquake in 1655, re-built in the fame ftyle by king Jofeph. The town has four parifh churches, and the number of inhabitants is eftimated at 1900. Cintra is the fummer refidence of the opulent inhabitants of Lifbon, and efpecially of the foreign merchants, and of perfons in high rank under government. The months of Auguft and September, when every thing is parched round Lifbon, are paffed here on mountains that afford plenty of water, verdure, and fhade. In the midft of fummer the nights are cool, and the houfes, which are difperfed among rocks, gardens, and wood, prefent an agreeable retirement. The mountains of Cintra, called by the ancients "Montes Lunæ," lie N.E. and S.E. and terminate in the Cabo de Rocca. They confift of granite compofed of clear-white quartz, a fomewhat reddifh felfpar, and black mica, againft which leans a white or foliaceous limeftone, or a proper ftink-ftone. The fouth fide toward Lifbon is arid, naked, parched up, confifting of bare heaped-up rocks, and affords a wild, defert, dreary profpect. But on the north fide, at the entrance of Cintra, every thing feems to be changed. The whole declivity to a certain height is covered with country-houfes and charming quintas, forming a fhady wood of the fineft trees, fuch as oaks of various kinds, pines, lemons, and other fruit-trees. Streams iffue every where from the rocks, and form cool moffy fpots. Towards the fummit of the mountain naked rocks are accumulated together. On one of the high points, floating, as it were, in the air, is feen a monaftery, and on another the ruins of a Moorifh caftle. Where the quintas ceafe, begins a thick but low coppice of ftrawberry-tree, mock-privet, buck-thorn, and gale or fweet-willow, together with other vegetable inhabitants of the ifland of Madeira. A fine profpect of the well-cultivated valley of Colares, of the great monaftery of Mafra, and of the fea, complete the beauties of the fcene. To the weft of Cintra is a market-town, called *Colares*, (which fee); and on the mountain, towards the weft, is a fmall monaftery of Capuchins, built between rocks, and called "Cork Monaftery," the rocks being cafed with cork. The elevation and vicinity to the fea caufe a great accumulation of clouds and moifture, which render it expedient to have a coating of cork upon the walls. Snow is not uncommon here in winter, although it never lies. Toward Cabo de Rocca the mountains become lower and lower, terminating in a flat, defert, naked, lonely ridge, which forms the cape. The height toward the fea is from 50 to 80 feet, being broken ftraight off, and confifting of granite. Near the extremity is a light-houfe, and not far from it a fmall chapel. On this naked plain the ftorms rage with great violence, the fea burfts with vehemence againft the rocks, and is very deep in their vicinity. From hence are feen the mountains of Mafra, and oppofite is the correfponding cape, Cabo de Efpichel. Farther to the northward is another chain of mountains, parallel to thofe of Cintra, with which it unites by high and detached mountains, the Cabeça de Montachique and others. From the fea thefe mountains appear like a lofty amphitheatre. This chain of mountains confifts of thick and foliaceous limeftone. On the part which runs toward the fea is the caftle of Mafra, built by John V. with its monaftery. Of the fize of this edifice, an idea may be formed from the quantity of metal ufed in every tower for bells, bars, &c. amounting to 14,502 arrobas (each arroba being 32lb.) for each tower.

CINTRE, in *Building*, the mould on which an arch is turned; popularly called *centre*, fometimes alfo *cradle*.

CINYPS, or CINYPHUS, in *Ancient Geography*, a river of Africa, in the Regio Syrtica, or northern part of the prefent kingdom of Tripoli, owing its name, according to Bochart, to the great number of porcupines produced in the adjacent country, derived its ftream from a fountain, or a hill, called "Zachabari," or the hill of the Graces, (as the name imports in the Punic, Phœnician, or Libyan) in the country of the Macæ, and emptied itfelf into the Sinus Syrticus. Pliny and Herodotus intimate that in this region there was a fruitful diftrict called "Cinyphe," which, as well as a city of fome repute mentioned by Scylax, might have been fo called from the river of the fame name. The Macæ, from whofe country the Cinyps flowed, were a pretty potent nation. They fhaved their heads all over, except the middle, where they permitted a lock of hair to grow. When they made war upon any of their neighbours, they wore the fkins of oftriches inftead of armour. In the winter they drove their flocks to the fea-fide, and in fummer to the inland places near fome fountain or river, for the fake of water. They are denominated by the ancients Macæ Cinyphii and Macæ Syrtitæ, from their vicinity to the Cinyps and the Greater Syrtis.

CINYRA, in the *Jewifh Antiquities*, a mufical inftrument. This and the Hebrew *cinnor*, which is generally tranflated *cithara, lyra*, or *pfalterium*, are the fame. It was made of wood, and was played on in the temple of Jerufalem. Jofephus fays, that the cinyra of the temple had ten ftrings, and that it was touched with a bow. In another place he fays that Solomon made a great number of them with a precious kind of metal called *electrum*, wherein he contradicts the Scripture, which informs us that Solomon's *cinnors* were of wood.

CINYRAS, in *Fabulous Hiftory*, the firft king of the ifland of Cyprus, was the grandfon of Pygmalion, and father of Adonis. Paphus, his father, is fuppofed to have been the firft that introduced into the ifland the worfhip of Venus, and is faid to have built the city which bears his name. He had, according to the fable, Adonis by his own daughter Myrrha. Paphus is feigned by the poets to have been the fon of Pygmalion, by a woman, who had before been an ivory ftatue. Pygmalion, they fay, upon his arrival in the ifland of Cyprus, faw that the women lived very licentioufly, and determined never to marry. Afterwards, as he was a famous ftatuary, he made an ivory ftatue of fuch perfection, that, falling in love with it, he prayed the goddefs Venus to procure for him a wife as beautiful as the ftatue he had made. The goddefs heard his prayer, and changed

changed the ſtatue into a fair damſel, by whom he had Paphus, the father of Cinyras. This Cinyras is ſaid to have poſſeſſed immenſe riches, inſomuch that "The wealth of Cinyras" became proverbial, for expreſſing an over-grown eſtate. As the worſhip of Venus was firſt eſtabliſhed in Cyprus by Paphus the father of Cinyras, both he and his deſcendants were buried in the temple of Venus at Paphos, an honour which was granted to no other family. The prieſthood of Venus was likewiſe entailed on their race, a dignity which they preſerved for many ages, after the throne was ſeized by others.

CINYRIA, in *Ancient Geography*, a town of the iſland of Cyprus, famous for the worſhip paid in it to Urania. It did not ſubſiſt in the time of Pliny.

CINYRUS, a mountain of Italy, placed in the Picenum.

CINZANO, in *Geography*, a town of Piedmont; 5 miles S.S.E. of Chivazzo.

CIOLI, Valerio, in *Biography*, a ſculptor of ſome eminence, who was born about the year 1530, at Settignano, a village near Florence, which, from its vicinity to ſome excellent quarries of ſtone, has at all times furniſhed a number of good ſculptors. Valerio was, in his infancy, inſtructed by his father, Simone Cioli, a ſculptor of ſome merit; but, at the age of 15, he was placed under Tribolo, an artiſt of conſiderable reputation, who at that time was employed in works of ſculpture and architecture by the duke Coſimo, at one of his villas near Florence.

Having ſtaid four years with Tribolo, he went to Rome, where he put himſelf under the tuition of Raffaello da Montelupo, one of the beſt imitators of the ſtyle of Michael Angelo; by whom he had indeed been employed in the execution of ſome of the ſtatues for the celebrated monument of Pope Julius II.

Having finiſhed his ſtudies, he was for ſome time employed to reſtore many of the ancient mutilated ſtatues; but he was afterwards choſen for a work which allowed greater ſcope to his abilities; it is the figure of Sculpture, who is repreſented in a diſconſolate attitude, weeping the loſs of the great Michael Angelo Buonaroti, and is one of three ſtatues which adorn his tomb in the church of St. Croce at Florence.

It is to be regretted, that a great part of the life of Cioli was ſacrificed in the execution of the ridiculous groteſque figures in the gardens of Boboli, which, though intended to ornament, are alone calculated to call forth ſentiments of pity or contempt, for the puerile and corrupt taſte which gave them birth. He died, aged upwards of 70, and left a ſon, Simone Cioli, who followed the profeſſion of his father, but who poſſeſſed ſmall talents. Gherardo Silvani was likewiſe his diſciple. Baldinuci, Dec. 1. della Par. 3. del. Sec. 4.

CION, in *Anatomy*, is ſometimes uſed for the uvula.

Cion, or Cyon, in *Gardening*, a young ſhoot, ſprout, or ſprig, put forth by a tree.

Grafting is performed by the application of the cion of one plant upon the ſtock of another.

To produce a ſtock of cions for grafting, planting, &c. the gardeners ſometimes cut off the bodies of trees, a little above the ground, and only leave a ſtump or root ſtanding; in this caſe the redundant ſap will not fail next ſpring to put forth a great number of ſhoots.

In dreſſing dwarf-trees, a great many cions are to be cut off. See Pruning.

CIONE, Orgagna (da) Andrea. See Orgagna.

CIONES, in *Antiquity*, a kind of idols very common, being only oblong ſtones, erected pillar-wiſe; whence alſo they had their name.

CIOS, Esker, in *Ancient Geography*, a river of Thrace, the *Oeſcus* of Pliny, and thus denominated by M. D'Anville, had its ſource in the N.W. part of mount Rhodope, in the country of the Pæonians. It paſſed by mount Hæmus, near its middle, and, purſuing its courſe through the weſtern part of the Triballic plain, emptied itſelf into the Iſter, near one of the two towns which bore the name of Oeſeus.—Alſo, a river of Aſia Minor, in Bithynia, which watered a town of the ſame name, according to Pliny. The town called Cios, was ſituated, ſays Pliny, in the place called Aſcania of Phrygia. Pomponius Mela ſays, that it was ſeated at the bottom of a ſmall gulf, formed by the Propontis; it is called in Greek, "Glio," in Turkiſh, "Kemlik."

The town of Cios had been built, according to Ariſtotle, by Cios, who conducted thither a colony of Mileſians. Euſtathius ſays, that Cios was one of the companions of Hercules. The town was deſtroyed by Philip, father of Perſeus, and king of Macedonia, and its territory ſurrendered to Pruſias, king of Bithynia, who rebuilt it, and gave to it his own name, Pruſias.

CIOTAT, La, in *Geography*, a ſea-port town of France, in the department of the Mouths of the Rhone, and chief place of a canton, in the diſtrict of Marſeilles, ſeated at the bottom of a bay in the Mediterranean, in a country which produces delicious fruit, oil, and excellent wine. The harbour is in the form of a horſe-ſhoe, and defended with ſeveral forts; 4 leagues S.E. of Marſeilles, and $7\frac{1}{2}$ S.S.E. of Aix. The place contains 5770, and the canton 8738 inhabitants; the territory includes $162\frac{1}{2}$ kiliometres, and 4 communes. N. lat. 43° 10′. E. long. 5° 31′.

CIPHER, or Cypher, in *Arithmetic*, one of the numeral characters called figures, and formed thus 0. The word *cipher* is probably derived from the Hebrew ספר, *ſaphar*, *to number*. By the Italians it is written *Zifra*, by the French *Chiffre*, and by the Low Latins *Ciphra*. It is, therefore, more properly ſpelt cipher than cypher.

The arithmetical cipher by itſelf implies a privation of value, or nothing: but when diſpoſed with other figures, ſituated on its left, in common arithmetic, it ſerves to augment each of their values by tens; and in decimal arithmetic, it leſſens the value of each figure to the right thereof, in the ſame proportion. See the article Arithmetic.

A cipher alſo denotes a kind of enigmatical character, compoſed of ſeveral letters interwoven together, fancifully; which repreſent the initial letters of perſons' names, and are frequently uſed on ſeals, coaches, and articles of plate, or other moveables.

Formerly, when merchants and tradeſmen were not allowed to uſe armorial bearings, they had ciphers thus artificially compoſed in their ſtead; which moſtly conſiſted of the firſt letters of their names, curiouſly inter-twined about a croſs, &c. of which many inſtances remain on ancient tombs: but the cuſtom ſtill obtains among perſons of various ranks in life, as an ornamental device, eſpecially on ſeals, or carriages. This practice has, indeed, been increaſed of late, to avoid the annual tax of two guineas impoſed in Great Britain, on thoſe who paint their family arms upon carriages. See Heraldry.

Cipher, in *Diplomatic Affairs*, ſignifies an occult manner of writing, legible to thoſe only who poſſeſs the key or ſecret, and hence the term *Deciphering*, which ſignifies to explain what is written in *cipher*. We believe this art was ſo called from the early cuſtom of uſing arithmetical characters or figures, for the purpoſe of ſecret correſpondence; a practice ſtill very common in the courts of princes, and for the ſkilful management of which a decipherer is attached to the office of the ſecretary of ſtate for foreign affairs. This

This art has been so much cultivated by the moderns, as to have acquired the importance of a distinct science, and is called *cryptology*, *cryptography*, *polygraphy*, *steganography*, &c.

In the present article we shall touch upon all the parts of this science, by whatever names they have been distinguished, although it must be allowed that the term *cipher* is only applicable to private writing. When we consider the noble and pre-eminent advantages of alphabetical writing, an art which so peculiarly distinguishes civilized society from uncultivated barbarians, and the very gradual progress it is likely to have made towards a state of perfection, we cannot reasonably suppose the practice of writing in cipher was common in the remotest ages of antiquity. To communicate our thoughts at a distance, by means of arbitrary and visible marks, was in its rudest form a vast effort of the human mind; and we must imagine that many centuries would elapse, before writing was so perfect and universal as to render it necessary to adopt any more abstruse modes of concealment. See LETTERS, CHARACTER, and WRITING.

A general sentiment has, indeed, prevailed among the literati, that the Egyptians invented hieroglyphics in order to hide and secrete their wisdom from the vulgar; a mistake, which the very learned bishop Warburton, (Divine Legation, b. iv. § 4.) has sufficiently confuted. Nay, we might with as good reason fancy the ancient picture-writing of the Mexicans, or the more refined hieroglyphical characters of the Chinese, to have been contrived for the purposes of secrecy, and not for the diffusion of knowledge! See the article HIEROGLYPHICS.

Letters were undoubtedly a much later invention than emblematical or symbolical writing; and, in their infancy, they must have been so puzzling as to appear endowed with an almost miraculous faculty. But, when this exquisite contrivance had become familiar to the vulgar eye, and would no longer serve to conceal the mysteries of statesmen, or the intrigues of designing subjects, the use of ciphers began to be foreseen. The want of them was at first supplied by artifices of different kinds, but chiefly by newly constructed alphabets; which, being intended only for the use of princes, ambassadors, generals, and other public personages, were not disclosed to the world at large. Even so late as the time of lord chancellor Bacon, and in this free country, it was considered as an aggravation of earl Somerset's crime to employ secret writing. "They made play," says lord Bacon, "of all the world besides themselves; so as they had ciphers and jargons for the king, queen, and all the great men, things seldom used but either by princes and their ambassadors and ministers, or by such as work and practise against, or at least upon, princes." Bacon's Remains; Charge against the Earl of Somerset.

It is too much to be lamented that, on some occasions, disaffected, treacherous, and ill-designing men have greatly abused this curious department of science, by applying it to the basest and most mischievous purposes: but we ask, Is this a reason against using or divulging it? Is it a sufficient plea for suppressing all we know on the subject, and endeavouring to stifle our knowledge, lest it should chance to be perverted? Would not a similar argument hold good for preventing the use of the press itself, and even for destroying books altogether? What useful thing has not been abused? And if this art should be turned to any purpose subversive of society, we have laws and magistrates to punish the offenders. It has been well observed by bishop Wilkins, (in his "Mercury, or The Secret and Swift Messenger,") that "nothing hath occasioned more troubles and contention than the art of writing, which is the reason why the inventor of it is fabled to have sown serpent's teeth; and yet it was but a barbarous act of Thamus, the Egyptian king, therefore, to forbid the learning of letters. We may as well cut out our tongues, because that member is *a world of wickedness!* If all those useful inventions that are liable to abuse, should, on that account, be concealed, there is not any art or science which might lawfully be professed."

The authors who have written either formally or incidentally on the subject of secret-writing, are by no means few in number; but they are not often consulted, nor always very easy to be met with; and it is surprising to find how seldom they are quoted by writers on bibliography and general literature. In the last edition of the Encyclopædia Britannica, and in the article *Chiffres* of the large French Encyclopédie (Departm. Diplomat. tom. i. part ii. p. 538.) mention is made of only three or four (and these not the principal) authors; so that we conceive it may be interesting to point out those who have most distinguished themselves in this science, at different periods, and in various nations. We shall, however, attempt to compress our historical remarks into as narrow a compass as possible.

The art of corresponding by visible signs may be supposed to have existed before the introduction of writing, and might have been practised by gestures or motions of the body; since infants are able to express themselves in this way, before they have acquired the faculty of speaking: but, whether or not the practice of holding secret information by signs of this nature, was carried to any great extent by the ancients, we are unable to say. Ovid takes notice of the art of discoursing thus, in the lines following:

> "Verba superciliis sine voce loquentia dicam.
> Verba leges digitis, verbaque vultus habet."

And again:

> "Sæpe tacens vocem, verbaque vultus habet."

Schottus, in his "Steganographia," exhibits an arthrological alphabet in Latin and German; also Mr. Falconer, in his "Cryptomenysis Patefacta," and Bp. Wilkins in his "Mercury" chap. xiv. have given us a similar one in English.

As to the art of discoursing with the fingers, named dactylogy and cheirology, it has been often commended for its antiquity: since the ancients used to express any number under 100 by the fingers of the left hand; and above 100, and under 1000, by those of the right hand. Moreover, Pierius has particularly described their methods of reckoning from 1 to 9000: and hence Juvenal says,

> "Rex Pylius, magno si quicquam credis Homero,
> Exemplum vitæ fuit à cornice secundæ;
> Fælix nimirum, qui tot per sæcula vitam
> Distulit, atque suos jam dextra computat annos."

To employ this manœuvre for the purposes of secrecy, Schottus has afforded us another alphabet; and so likewise has the celebrated George Dalgarno, in his "Didascalocophus," p. 74, who distinguished himself in the reign of Charles II., by an endeavour to introduce an universal character and philosophical language.

Among the signs for nightly information at a distance, those by fire are extremely common, and have been used by the Chinese, Persians, and other nations, in the remotest times. This species of communication is affirmed by Diodorus Siculus to have been practised by Medea in her conspiracy with Jason, which carries us back three thousand and seventy years; and although there must be some uncertainty on this question, Pliny, in his "History," lib. vii. cap. 56, says it originated with Sinon. "Specularem significationem Trojano bello Sinon invenit." This was the

the ſignal upon which Sinon agreed to unlock the wooden horſe, in the ſiege of Troy, about 1184 years before Chriſt:

> " ——— Flammas cum regia puppis
> Extulerat ————————."
>
> Virgil, Æn. lib. ii. 256.

And, after the taking of Troy, Æſchylus relates, that Agamemnon immediately apprized his queen, Clytemneſtra, of that event by a ſimilar method; which, we ſuppoſe, muſt have been done either by men placed at certain diſtances with lighted torches, which they held up in ſucceſſion, or by a conſiderable number of fires on the tops of hills, denoting the ſimple fact previouſly agreed on between the parties. See Onoſander's Strategicus, cap. 25, where this practice is deſcribed.

The fire-ſignals of the Greeks and Romans are also ſlightly mentioned by Quintus Curtius, Livy, Cæſar, Herodotus, Homer, and Thucydides; likewiſe by Vegetius and Frontinus; but ſtill more in detail by Polybius, and Æneas Tacticus; the latter of whom was contemporary with Ariſtotle, and has left a valuable fragment on the duties of a general, (tranſlated into Latin by Caſaubon,) wherein are many curious remarks on the ſubject of ſecret correſpondence. The Greek ſignals were much improved by Polybius, who, in his hiſtory (Lib. x. cap. 45. p. 296. tom. iii. Lipſ. 1790. edit. Joh. Schweighaeuſer.) attributes the invention to Cleomenes and Democritus, or (more correctly) to Cleoxenus and Democlitus, in words thus rendered: "Poſtrema ratio, cujus auctores ſunt Cleoxenus & Democlitus, ſed quam nos correximus, certa definitaque eſt, adeo ut quidquid exortum fuerit negotii, id poſſis certo facere notum." Prior to that period, the information communicated by torches, flags, ſmoke, or otherwiſe, was very limited, and it was requiſite to ſettle beforehand, what each ſignal ſhould mean; whereas Polybius ſhewed, how to correſpond alphabetically, and to give or receive any ſpecies of intelligence, without this previous concert. The plans of Æneas Tacticus had never arrived at ſuch perfection, and were therefore of comparitively ſmall uſe; though, without doubt, he at leaſt equalled any of his predeceſſors in the facility of his telegraphic communications. Vid. Polyb. L. x. ſub finem.

Polybius has detailed the peculiar invention of Æneas; which conſiſted of a narrow earthen veſſel, filled with water, and having a tube or aperture to let off the fluid: a piece of ſtick is then to be thruſt through a cork, ſo as to float above the ſurface, when it is put into the water; and the upper part of this ſtick is to be marked by ſubdiviſions, of three inches each, upon which are to be written ſuch common events as happen in war. When the water is drawn off from any of theſe veſſels, which muſt agree exactly in ſize, &c. it is evident that the ſticks will ſink lower as the veſſels become empty; ſo that on obſerving the ſpace through which the ſticks deſcend, the correſpondents may (by the help of a ſimilar apparatus) tell which of the expected events has occurred. But Polybius, finding this contrivance adapted only for thoſe few occurrences which had been previouſly written on the ſticks, deſcribes his own method, which was far ſuperior.

We are told, however, that Æneas Tacticus collected together about twenty different modes of writing, which could only be underſtood by perſons who were in the ſecret; part whereof were his own, and part of them invented by others; ſo that this author ſeems to have been well verſed in the art of ſecret correſpondence, as it then exiſted among the ancients.

We ſhall hereafter have occaſion to notice ſome of the ſecret modes of writing recorded by Æneas; but, it will firſt be proper to explain and illuſtrate the telegraphic invention of Polybius himſelf, which is as follows:

Divide the letters of the Greek alphabet, into five parts, each of which will conſiſt of five letters, except the laſt diviſion, which will have only four. Let theſe be fixed on a board in five columns. The man who is to give the ſignals is then to begin by holding up two torches, which he is to keep aloft till the other party has alſo ſhown two. This is only to ſhow that both ſides are ready. Theſe firſt torches are then withdrawn. Both parties are provided with boards, on which the letters are diſpoſed as formerly deſcribed. The perſon then who gives the ſignal is to hold up torches on the left, to point out to the other party from what column he ſhall take the letters as they are pointed out to him. If it is to be from the firſt column, he holds up one torch; if from the ſecond, two; and ſo on for the others. He is next to hold up torches on the right to denote the particular letter of the column that is to be taken. All this muſt have been agreed on before-hand. The man who gives the ſignals muſt have a dioptrical inſtrument (διοπτρον), conſiſting of two tubes, and ſo placed as that, by looking through one of them, he can ſee only the right ſide, and through the other only the left, of him who is to anſwer. The board muſt be ſet up near this inſtrument; and the ſtation on the right and left muſt be ſurrounded with a wall (παραπεφραχθαι) ten feet broad, and about the height of a man, that the torches raiſed above it may give a clear and ſtrong light, and that when taken down they may be completely concealed. Let us now ſuppoſe that this information is to be communicated—*A number of the auxiliaries, about a hundred, have gone over to the enemy.* In the firſt place, words muſt be choſen that will convey the information in the feweſt letters poſſible; as, *A hundred Cretans have deſerted*, Κρητες εκατον αφ' ημων ηυτομολησαν. Having written down this ſentence, it is conveyed in this manner. The firſt letter is a κ, which is in the ſecond column; two torches are therefore to be raiſed on the left hand to inform the perſon who receives the ſignals to look into that particular column. Then five torches are to be held up on the right to mark the letter κ, which is the laſt in the column. Then four torches are to be held up on the left to point out the ρ (*r*), which is in the fourth column, and two on the right to ſhow that it is the ſecond letter of that column. The other letters are pointed out in the ſame manner. Such were the Φρυκτοι or Πυρσεια recommended by Polybius.

As this contrivance deſerves particular attention, and throws great light on a common mode of writing by cipher, we ſhall here attempt to give a further elucidation of it, by another example and a diagram.

Diſpoſe the letters into five rows or columns; place a figure over each of them, and another by the ſide of the five lines: but inſtead of Q, let K be its ſubſtitute: Thus,

1	2	3	4	5	
a	f	k	p	v	1
b	g	l	r	w	2
c	h	m	ſ	x	3
d	i	n	t	y	4
e	j	o	u	z	5

Provide ten torches, and let ſo many be held up towards the right hand as may denote the row in which the letter required is to be found; likewiſe ſo many on the left hand as ſhall point out the place of the ſame letter, reckoning from

from above. Proceed in this operation, till you have completed the word or ſentence to be communicated, as in the underwritten example; where the firſt figure in each pair ſhews the row, and the ſecond denotes the order of the letter. which being duly performed, the ſpectator will receive the following information:

52 . 15 . 41 . 15 . 42 . 24 . 43 . 23 . 12 . 54 . 21 . 11.
w e p e r i ſ h b y f a

33 . 24 . 34 . 15 . 11 . 34 . 14 . 14 . 24 . 43 . 15 . 11.
m i n e a n d d i ſ e a

43 . 15.
ſ e

An intelligent reader will perceive that five lights might do, for the purpoſe of repreſenting theſe five differences, as well as the ten; nay better, only taking care to pauſe ſufficiently after every ſeparate elevation of the torches, whether to the right or left hand. It is worthy of remark, that this very principle for diſtant communication has been recently adopted, in the conſtruction of a day-telegraph at the Admiralty! Although in the latter there are ſix ſigns for the purpoſe of repreſenting figures as well as letters. (See the articles SIGNALS and TELEGRAPH.) But we have advanced enough to ſhew that the ancients, 2000 years ago, knew how to maintain ſecret correſpondence by ſignals. We ſhall next prove that they were alſo acquainted with ſeveral means of *writing by cipher*; although it muſt be confeſſed, that the moderns have greatly improved upon their inventions of this kind.

Le Sieur Guillet de la Guilletiere, in his "Ancient and Modern Lacedemon," endeavours to ſhew that the Spartans were the inventors of writing in cipher; and that their Scytalæ were the firſt rudiments of this art. We ſuppoſe he has taken his account of the σκυτάλη from Plutarch: but as ſeveral modes of ſecret writing mentioned by Æneas Tacticus are entirely different from this, it by no means follows that thoſe of Æneas were ſuggeſted by the former; nay, we are diſpoſed to think, with Scaliger, that a little attention might have developed this cipher with eaſe.

The nature and uſe of the *Scytale*, according to Plutarch, in his life of Lyſander, was this: When the Grecian magiſtrates ſent out an admiral or a general, they prepared two cylindrical pieces of wood with ſo much exactneſs, that they were perfectly equal both in length and thickneſs. One of theſe they kept themſelves, and the other was given to the military officer then employed. When they had any ſecret and important orders to communicate to him, they took a long narrow ſlip of parchment, and rolled it round their own ſtaff, in a ſpiral form, one fold cloſe to another, and then wrote their communication upon the edges of the parchment. This done they took off the ſcroll, and ſent it to the commander; who, on receiving it applied it to his ſtaff, ſo that the broken and imperfect characters now became legible. The parchment as well as the ſtaff was called σκυτάλη. As this contrivance was had recourſe to by the Athenians and Lacedæmonians, in the time of Alcibiades, Pharnabazus, and Lyſander, we are certain it was invented at leaſt four centuries earlier than the Birth of Chriſt.

Although this confuſed ſort of writing, as it would appear upon the unrolled ſlip of parchment, is not a ſufficient ſecurity againſt detection in the preſent ſharp-ſighted age, there are other means of ſecret writing which even Scaliger's eyes (as biſhop Wilkins obſerves in his "Mercury") could not diſcover; "and therefore it was too inconſiderate and magiſterial a ſentence of him, thence to conclude all this kind of learning to be vain and uſeleſs. It is certain," adds the biſhop, "that ſome occaſions may require the exacteſt privacy; and it is as certain, that there may be ſome ways of ſecrecy, which it were madneſs for a man to think he could unfold;" in which opinion he is ſupported by Vegetius, Baptiſta Porta, and lord Bacon, as well as by ſeveral more recent judges; ſo that Scaliger ſhewed greater ſelf-confidence than ſkill, in pretending he could decipher any writing that might be invented. The author of the preſent article (who has only taken up this ſubject as an amuſement) challenges all the Scaligers in Europe to explain various kinds of cipher he has recently contrived, and which elude every rule laid down by his predeceſſors.

The learned Mr. Falconer, and ſome earlier writers on cryptography, have attributed the invention of the Lacedæmonian ſcytale to Archimedes the mathematician; but we have already afforded the reader evidence of its uſe in the days of Alcibiades, Pharnabazus, and Lyſander, who lived nearly two centuries prior to the time of Archimedes; and Plutarch does not ſpeak of this invention as *new*, or as being uſed by the Greeks alone, at that early period. See Plutarch, in his lives of Alcibiades and Lyſander.

We next deſcend to the age of Ariſtotle, about 350 years before Chriſt, when the art of ſecret writing ſeems to have aſſumed a more regular and ſyſtematic form; but the authors of that age and thoſe following, whoſe works have deſcended to poſterity, are ſo few and imperfect as to throw only a faint light on the object of our inquiry. We are ignorant of what was done by Julius Africanus, Laertius, and Philo-Mechanicus, three ancient Grecians, who treated on this ſubject. Æneas Tacticus, and Polybius, are our principal guides; the former of whom was contemporary with Ariſtotle: (vide "Æneæ Vetuſtiſſimi Tactici Commentarius, De tolerandâ Obſidione, Caſaubono interprete," 1610, 8vo.)

Æneas is ſaid by Polybius, to have collected and invented a great number of ſecret modes of correſponding; and among them, we imagine, are included thoſe few which he has briefly recited in the above named work. He ſeems to have approved eſpecially of affixing ſmall dots to the letters of any book or epiſtle, written upon a common ſubject, in ſuch a way as only to denote the characters expreſſive of the ſecret ſentiment, all the reſt being non-ſignificant. He alſo recommends the ſubſtitution of points inſtead of vowels, and gives the two following ſhort ſpecimens:

D :·· :: N ::: S :· ::· S P ::· L C H ·· R, which ſignifies DIONYSIUS PULCHER.

H ·· R · C L :· D ·· S V ·· N :· T ::· which ſtands for the words HERACLIDES VENITO.

This mode may be varied indefinitely; for it is of no importance what arrangement or number of points is ſubſtituted for the vowels; and, although we cannot ſay this is very difficult to decipher, it nevertheleſs demonſtrates the fact of ſecret writing being employed in thoſe remote ages. The ſame author likewiſe mentions the artifice of paſſing a thread through holes in a board or tablet, correſponding with the twenty-four Greek letters; which Guſtavus Selenus (an aſſumed name of the duke of Brunſwick and Luneburg), who publiſhed a folio book on cryptography, A.D. 1624, has therein deſcribed more at large. The order of the threads, expreſſing the alphabetical characters, previouſly ſettled by compact, will repreſent any words we pleaſe.

There is a great affinity between this method, and that of tying knots upon a ſtring at various diſtances from each other, ſo as to agree with a determinate meaſure, graduated for the purpoſe. Few people would ſuſpect any private news or treachery to lie hidden in a piece of knotted thread. Biſhop Wilkins has farther illuſtrated this device, in the 5th and 11th chapters of his "Secret and Swift Meſſenger;" and we have given a repreſentation upon *Plate* II. *fig.* 1. of the graduated meaſure alluded to, with knots

knots tied upon the thread oppoſite to the letters F, L, Y, from which any perſon may learn how to put this plan into execution.

The ſame effect will be produced if, in lieu of the knots, the thread be marked with ink at the proper intervals oppoſite each letter; or, if the tablet, or the meaſure, be applied to paper, and dots are impreſſed upon it under the holes or ſubdiviſions which ſtand for the reſpective letters. The ancients have laid down the principle, which is thus eaſily varied in practice; but the merit of this invention belongs to them rather than to the moderns.

Æneas was acquainted with many other modes of occult writing beſides theſe, ſome of which are alluded to in his Poliorceticus, § xxxi. but the greater number are wholly loſt. And it is truly ſurpriſing, that theſe methods of correſpondence ſhould not have been more univerſally carried into effect by ſucceeding generations, ſo as to have prevented the loſs of them! Surely the telegraphic apparatus of Polybius, with five or ten flambeaux, might have been employed and improved upon, for the moſt important military or national purpoſes; and yet the moderns ſcarcely have dreamed of uſing any ſuch means of alphabetical communication till the preſent age! How obvious it ſeems, that this contrivance of Polybius, with ſome variation in the materials, ſhould be deemed at leaſt as applicable for daily uſe, as it was found to be for nightly obſervations! And, how numerous are the ſpecies of ciphers which a man of common ingenuity would extract from the principles ſuggeſted for ſecret writing in Æneas's little treatiſe!

He likewiſe deſcribes ſeveral ways of fraudulently conveying intelligence into a beſieged town, &c. For example, by the application of a manuſcript to a ſore leg, inſtead of a plaiſter or bandage;—by ſewing up an epiſtle within the ſole of a perſon's ſhoe, or hiding it under the arm-pit;—rolling thin leaves of lead into the form of ear-rings, &c. after having written thereon;—putting a bladder into a bottle of oil, firſt inſcribing upon it, and inflating it ſo as to fill the bottle completely;—or writing on a tablet, and afterwards covering it over with melted wax;—to which are added ſome other ſingular propoſals, ſhewing the fertility of invention exerciſed by the ancients on ſuch occaſions.

But the ſtrangeſt contrivance was that of Hyſtiæus, mentioned by Herodotus; who, while at the Perſian court, ſent to Ariſtagoras in Greece, a ſervant affected with bad eyes, pretending that his hair muſt firſt be ſhorn, and his head ſcarified; in performing which, Hyſtiæus imprinted his ſecret intention, in legible characters, upon the ſervant's head, and kept him in cloſe confinement till the hair grew; when he deſired him to travel to Ariſtagoras for a perfect cure, who, on the man's arrival, repeated the ſhaving, and thus obtained the ſecret information tranſmitted by means of the ignorant meſſenger.

As a meſſage may be concealed by adopting any arbitrary marks, (for inſtance the dots of Æneas) inſtead of letters, ſo likewiſe by changing their powers, and ſubſtituting one character for another; which is ſaid to have been practiſed in that kind of cabbaliſm which the Jewiſh rabbies call צירוף, or combination. Biſhop Wilkins has cited examples of this ſort among the Hebrews; and it was alſo practiſed among the Romans, as Suetonius relates of Julius Cæſar and Octavius Auguſtus; the former of whom wrote the fourth letter inſtead of the firſt, *i. e.* D for A, the fifth for the ſecond, the ſixth for the third, &c. &c.; and Auguſtus wrote after the ſame method, only by putting the ſecond for the firſt, and the third for the ſecond, *i. e.* B for A, C for B, D for C; which confounds the general appearance of the writing, but is not ſufficiently intricate to eſcape the ſcrutinizing eye of a modern decipherer. However imperfect and inadequate this ancient mode may be, it is quite as good as three-fourths of thoſe ciphers which the principal courts of Europe truſted to, until after the ſixteenth century! It is a matter of indifference, whether we change the powers of the letters, or invent a new-formed alphabet for ſecret writing; as the ſame rules for deciphering one of them will equally well apply to the other. And yet we find, for many centuries after the Auguſtan age, that kings and ambaſſadors contented themſelves with only changing the form of their alphabets, as if this were any ſecurity againſt detection! It demonſtrates how little men addicted themſelves to this ſubject as a SCIENCE, while they felt an indiſpenſable neceſſity for having recourſe to it as an ART.

We do not indeed affirm, that there is ſo much reaſon now to complain of the negligence of princes and ſtateſmen in this reſpect, as there was formerly; but we are in poſſeſſion of certain facts, which ſhew that the words of lord chancellor Bacon are not entirely inapplicable to our own times, viz. "If the ciphers in uſe were good and truſty, ſeveral of them would abſolutely elude the labour of the decipherer; and yet remain commodious enough, ſo as to be readily wrote and read; but through the ignorance and unſkilfulneſs of ſecretaries and clerks, in the courts of princes, the moſt important affairs are generally committed to weak and treacherous ciphers." We have much cauſe to doubt, whether any court in Europe, even at this time (1807), can lay claim to a cipher, having the three eſſential properties required by lord Bacon; "1ſt, That it be eaſy to write and read; 2d, That it be truſty and undecipherable; 3d, That it be clear of ſuſpicion." But we refrain from divulging all we believe on this delicate topic:—*Verbum ſapienti ſat eſt.* It may be ſaid, that no individual ought to diſcloſe an inſcrutable cipher, unleſs he is compelled by imperious circumſtances.

The practice of tranſpoſing the ordinary letters of the alphabet, to perplex the reader, was not only reſorted to by the Romans, but alſo by the Greeks, Syracuſans, Carthaginians, and perhaps by other enlightened nations. The ancient Gauls, Saxons, Normans, &c. uſed more commonly to employ new and uncouth alphabetical characters for ſecret writing; many examples of which were collected by Trithemius, and the other ſyſtematic authors on polygraphy, in the 15th and 16th centuries.

But the method of repreſenting whole words or ſyllables by arbitrary marks, ſaid to have been firſt introduced by the old poet Ennius, was much more perplexing, and was encouraged by Mæcenas, Cicero, Seneca the elder, Philargirus, Fannius, Aquila, and Tyro: thouſands of theſe ſyllabic characters may be ſeen in Valerius Probus, Paulus Diaconus, Goltzius, and (in 200 folio pages) at the end of Gruter's Inſcriptions.

Although thoſe Tyronian characters, as they are uſually named, were not alphabetical, we obſerve among them a great many bearing a conſiderable reſemblance to each other, when they denoted words beginning or ending with the ſame Latin particles; ſo that this kind of ταχυγραφια, or βραχυγραφια, was not compoſed entirely at random, but according to ſome preconceived ſyſtem.

The Tyronian *notæ*, we are told by literary perſons, were augmented in the time of Seneca to the number of thirteen thouſand! And ſo completely did they anſwer the purpoſe of ſecret writing during the monkiſh ages, that an old copy of a pſalter, found inſcribed with theſe characters, was ignorantly entitled "Pſalterium in Lingua Armenica." Nay, pope Julius II. employed learned men, without ſucceſs, to decipher them.

Herman Hugo, in his work "De Origine Scribendi," maintains

maintains an opinion of this writing having been ufed among the ancient Hebrews, and that it is alluded to in Pfalm xlv. 1, and Daniel v. 25; but this needs further evidence, and is no better fupported than the opinion fome men hold of Englifh fhort-hand, which is alphabetical, having originated from the Tyronian characters, which are not alphabetical.

Another ancient fort of writing employed among the Romans more than any nation befides, was that of abbreviating words or fyllables, by omitting the final letters, and fometimes placing points or dafhes in their ftead. Thefe figlæ, as they were called, from the word figillæ, ufed to be chiefly infcribed on ftatues, arms, coins, public records, monuments, &c. for the fake of brevity, rather than of fecrecy; and, therefore, do not particularly come under our confideration in the prefent article, although moft authors upon Cryptography have taken notice of the SIGLÆ. (Vide Waltheri Lexicon Diplomaticum, 1752, and Gerrard's Siglarium Romanum, 1792.)

To bring thefe hiftorical remarks towards a conclufion, we fhall now refer to the chief modern writers on the fubject of *ciphers*, whofe names have come to our knowledge; fome of whom, indeed, have treated more formally and copioufly on the art of fecret-writing than others, but all of them deferve mention, and may be confulted with advantage. We prefix an afterifm * to the names of a few authors who, in our judgment, have principally diftinguifhed themfelves, and merit an attentive examination.

The firft writer among the moderns, and the man who may be faid to have led the way in fecret writing, for we have no work of any importance before his time, was the * Abbé Trithemius, a Benedictine, whofe erudition and acumen were fuch, that he was fufpected of magical practices in the exercife of this art. He compofed two extenfive treatifes; one of which, entitled "Polygraphia," was publifhed in the year 1499, but the other, called "Stenographia," was not printed during his life. He alfo made fome progrefs towards the completion of a third work at the inftigation of the emperor Maximilian. His "Polygraphia" was tranflated into the French language by Gabriel de Collange, during the year 1561; but, prior to its appearance, three other authors had written on this topic; viz. Palatino, in 1540, Bellafo, in 1553, and Glauburg, in 1560: and in the year 1563, the public were prefented with another original treatife, by * Baptifta Porta, an author of confiderable merit. Nearly about the fame period, this fubject was handled by Cardanus and Bibliander; afterwards by * Blaife de Vigenere, Walchius, Ifaac Cafaubon, * Schottus, * Guftavus Selenus, Gerrard Voffius, Herman Hugo, Schwenter *alias* * Hercules à Sunde, Wecker, Niceron, * Lord Bacon, Cafpi, Seeländer, * J. Balthafar Friderici, Comiers, Bafaccioni, La Fin, Dalgarno, Becher, Hiller, * Bifhop Wilkins, J. Nicholaus, Buxtorff, Caramuel, Wolfgang, * Falconer, Horfley, P. Crinitus, Erneft Eidel, J. Gefory, J. C. Amman, Ozanam, * Breithaupt, * Conradus, Dutton, Davys, Ware, Gravefande, Twifs, De Vaines, Cafpi, Carpentier, Bifhop Warburton, Staniflaus Mink, Lucatello, Kircher, Pafchius, Morhof, * Thickneffe, Hutton, Hooper, Aftle: to whom fhould be added the mathematician * Dr. Wallis, whofe valuable MSS. on this fubject are depofited in the Bodleian library; and the celebrated Marquis of Worcefter, whofe unpublifhed performance, written A. D. 1659, may be feen in the Harleian library, No. 2428. We have named the unedited works of thefe two Englifhmen, becaufe Dr. Wallis's papers have been often quoted or referred to by authors, and fome of them, indeed, have been printed fince his death; and becaufe the Marquis of Worcefter's "Centurie of Inventions," § 3d and 4th, contain an evident allufion to the fubject of the above MS. which was not difcovered to be his lordfhip's, until we lately recognized and verified it at the Britifh Mufeum.

Several authors who have treated largely on diplomatic affairs, likewife give fome account of writing by cipher; among whom we ought efpecially to notice the editors of the "Nouveau Traité de Diplomatique," tome iii. p. ii. §. iv. ch. x. and the article CHIFFRES in the Encyclop. Method:— "Economie Politique et Diplomatique." But, we confefs, that our expectations have been fometimes difappointed in works of that nature; for where we hoped to find the fcience handled moft learnedly and copioufly, we have found only meagre and trifling obfervations.

This remark alfo applies to what is written, or rather ftolen, upon the fubject of cipher, in the fucceffive editions of the Encyclopædia Britannica; wherein we find merely a long extract from Dr. Hooper's "Recreations," without acknowledgment, or any attempt at improvement! That article might, perhaps, be well enough adapted for the purpofe it was originally defigned, viz. as a "recreation" for fchoolboys; but cannot be regarded as an ornament to the great national work, into which it has been furreptitioufly tranfplanted.

Lord Bacon refers the practice of writing by cipher to the art of grammar, noting it as a deficient branch of knowledge; and, in reference thereto, it is treated by moft of thofe authors who have written on grammar; "that art," fays bifhop Wilkins, "in its true latitude, comprehending all the ways of difcourfe, whether by fpeech, or by writing, or by gefture, together with the feveral circumftances pertaining to them. So that, befides the ufefulnefs of this fubject" (viz. ciphering) "for fome fpecial occafions, it doth alfo belong unto one of the liberal arts." Now, among "the ways of difcourfe" which have been greatly improved and new-modelled of late years, we ought to mention the art of correfponding by *fignals at fea*; an art which the moderns have carried to fo great a pitch of excellence, that naval officers, in different fhips, can difcourfe with each other on almoft any topic of importance relative to their military duties. We fhall here add only a few words concerning naval fignals, as this topic will be hereafter difcuffed at large in a feparate article. See SIGNALS.

Whether the renowned fea-officers of ancient Greece and Rome had a fyftem of fignals analogous to that of Polybius by land, is a queftion which we want evidence to refolve; but we are not without proofs of their ufing fome fort of fignals, however fimple and inadequate we might now account them. Thus, we read when Ægeus fent his fon to Crete, that it was determined to difplay a white flag if the fhip conveyed back Thefeus in fafety; and in the hiftory of the Punic wars, mention is often made of certain rude methods of correfpondence; befides which, Ammianus Marcellinus fpeaks of the *vexillarii* and *fpeculatores*, and fome of the ancient coins reprefent both flags and ftreamers. Again, there is a direct allufion to fignals on fhip-board, by Virgil, Æn. iii. 519.—

> "Poftquam cuncta videt cœlo conftare fereno,
> Dat clarum è puppi fignum."

Alfo in Æneid ii. 255, before quoted; which implies that Agamemnon from his fhip, and Sinon from the citadel, gave fignals mutually to each other, whereby they were enabled to co-operate. But probably thefe methods were as different from the fignals by which the operations of modern navies are regulated, as the Chinefe hieroglyphics are different from our alphabetical characters. It was eafy to erect a flag, difplay a torch, or blow a trumpet; but to multiply and combine thefe or fuch like fignals by fea, fo as to form letters,

letters, words, and ſentences (either immediately or through the intervention of numbers) was a ſcience to which the ancients ſeem not to have attained.

From the inceſſant changes of poſition in ſhips at ſea, it is impoſſible to put in execution the ſame means of conveying intelligence as we have adopted by land; and, beſides this difficulty, the ſpace which can be ſpared for the diſplay of flags by day, and lights in the dark, is exceedingly limited on ſhips under ſail. The principle, therefore, by which naval communications are chiefly governed, conſiſts in the repreſentation of arithmetical numbers; for which purpoſe ten or twelve different flags, &c. are ſufficient, and fewer than ten would be inconvenient. (See the "Telegraphic Signals, or Marine Vocabulary," printed by Sir Home Popham in 1804, for the uſe of the Eaſt India captains.) By the artful combination of a few pendants or flags, naval officers can thus deſignate ſeveral thouſand figures, words, and ſentences, which are entered in oppoſite columns for the ſake of eaſy reference; and by night they can exhibit lanthorns, blue-lights, falſe-fires, or rockets, with the occaſional report of guns, in ſuch a way as to keep up a regular correſpondence. The lights diſplayed for ſignals in the dark, muſt always be arranged perpendicularly, to avoid any apparent change of their relative poſition, when viewed from ſeveral ſhips at a time.

For example: a ſingle light will repreſent 1; two, three, and four lights, placed vertically, may repreſent 2, 3, and 4; three lights over each other, two of which are placed at a certain diſtance below, and the upper one thrice as far above them, will denote figure 5; three perpendicular lights, reverſing the laſt order, may ſtand for 6; four lights, the two at each extreme being at a common diſtance, and a triple ſpace between the middle two, will repreſent 7; four lights, the three lowermoſt ones at a common diſtance, and the upper thrice as far, will ſignify 8; four lights, the three uppermoſt at a common diſtance, and the lower one at a triple diſtance, may denote 9; a falſe-fire, or a blue light, will ſtand for 0 or 10; and by the ſucceſſive exhibition of theſe, as they are wanted, any number of figures, denoting particular inſtructions or communications, can be made with the utmoſt certainty and preciſion. To render this example more clear, we ſubjoin the reſpective ſituations of the lights as deſcribed above: viz.

Lights.		Fig.
o	ſtands for	1
o o	- -	2
o o o	- -	3
o o o o	- -	4
o ⋮ o o	- -	5
o o ⋮ o	- -	6
o o ⋮ o o	ſtand for	7
o ⋮ o o o	- -	8
o o o ⋮ o	- -	9
A falſe fire	-	10

The greateſt impediment in executing this plan, will be the proper adjuſtment of the lights, ſo that they may be diſtinctly perceived. They ſhould be placed at leaſt fifteen or twenty feet apart; and the beſt ſituation for the ſignals repreſenting 5, 6, 7, 8, 9, will uſually be to hoiſt the upper lamp or lamps at the mizen-peak, and the lowermoſt at the enſign ſtaff: but if thoſe ſituations ſhould not be viſible from the other ſhips, let the upper lamps be hoiſted to one of the maſts'-head, and the lower ones to the ſhrouds of the ſame maſt.

By this method, then, it appears that only four lamps are ſufficient for nightly communications at ſea; and upon ſhore, or when a ſhip lies quiet at anchor, a ſtill ſmaller number of ſignals would be adequate to every exigency, as we ſhall evince preſently. Some laudable endeavours have been made to diſtinguiſh the lamps by different coloured glaſſes: but, at a great diſtance, theſe colours could not be diſcriminated with certainty, or the lights have been too feeble when ſeen through denſe glaſſes; in conſequence of which this project has wholly failed of ſucceſs, and can never be revived, except by mere ſpeculators.

Another mode of correſponding by *cipher*, (for all theſe modes come under this general denomination,) is by ſtriking on two or three bells of various ſizes; or by as many different kinds of audible ſounds of any other ſort, ſuch as, 1, a drum; 2, a fife; and, 3, a trumpet. We prefer to uſe three, for alphabetical purpoſes, which may be combined as follows, ſo as to repreſent each letter.

A	is repreſented by		111	N	is repreſented by		222
B	-	-	112	O	-	-	223
C	-	-	113	P	-	-	231
D	-	-	121	Q	-	-	232
E	-	-	122	R	-	-	233
F	-	-	123	S	-	-	311
G	-	-	131	T	-	-	312
H	-	-	132	U	-	-	313
I	-	-	133	V	-	-	321
J	-	-	211	W	-	-	322
K	-	-	212	X	-	-	323
L	-	-	213	Y	-	-	321
M	-	-	221	Z	-	-	322
				Blank, or Nothing		—	333

It muſt be remembered, that the three different ſounds ſtand for only one letter; and that a ſufficient pauſe muſt intervene after each letter, in order to prevent any confuſion. To keep an exact memorandum of this cipher, it will be neceſſary for the auditor to write either the figures, as above, or three alphabetical characters inſtead of them: for inſtance, D for drum, F for fife, and T for trumpet; but, in the uſe of three flags, ſuppoſe red, blue, and white, the letters R, B, and W, would be ſubſtituted.

This method of alphabetical notation is greatly preferable to the uſe of only two ſignals, becauſe it is more diſtinct and eaſy to remember; whereas, if we uſe but two ſigns, they muſt be often repeated, and combined for each letter, (*i. e.* at leaſt five times) as in the cipher of which the following is an example:

A	B	C	D	E	F	G
11111,	11112,	11121,	11122,	11211,	11212,	21221,

12222,	21111,	21112,	21121,	21122,	21211,	21212,
V	W	X	Y	Z	Nothing	
21221,	12121,	22212,	22221,	22122,	21222	

From

From the preceding alphabets may be feen how diftinctly any perfon can exprefs his mind by two or three fignals, addreffed either to the eye or the ear; and in correfponding with thefe ciphers, it will be found very convenient to interpofe the 333, or 21222 (which denotes a blank) between every word, in order to prevent the confufion that might arife from an accidental error. The effect will be the fame, whether the writer make ufe of arithmetical characters, letters, dots, lines, mathematical diagrams, or any other fign which admits of two or three differences. We fhall here add a fpecimen in dots, according to this laft alphabet of figures; where the period ftands for 1, and the colon for 2: the words thus reprefented fhall be the writer's name.

W I L L I A M — B L A I R

.:.:. .:... .::.. .::.. .:... ..... .::.: :.::: ....: .::.. ..... .:... : .:.

The objection which may be ftarted againft both thefe ciphers is, that they are too laborious, and not incapable of being deciphered by perfons of fkill in this art. The writer does not recommend the above mode of dot-writing as very expeditious, but as fimple; he knows it, however, to be much lefs operofe than many ciphers fubmitted to the public, and he can affirm that it is fully as difficult to decipher, as the celebrated plan of Lord Bacon, which he calls writing *omnia per omnia*. But, as an example of more ready and undecipherable writing by dots, of his own invention, the author refers to *Plate* III; whereon he has ventured to engrave the key itfelf, and yet defies any of his readers to explain the principle by which it is compofed, or to give him a fimilar piece of writing.

The moft legible and common ciphers in ufe, confift of a new alphabet, or of the ufual characters tranfpofed fo as to alter their powers: of this latter kind was the cipher of Julius Cæfar and Auguftus; viz.

For	a	b	c	d	e	f	g	h	i	j	k	l	m	n	o	p	q	r	s	t	u	v	w	x	y	z
Write	d	e	f	g	h	i	j	k	l	m	n	o	p	q	r	s	t	u	v	w	x	y	z	a	b	c
Or	b	c	d	e	f	g	h	i	j	k	l	m	n	o	p	q	r	s	t	u	v	w	x	y	z	a

Julius Cæfar's method "Per quartam elementarum literam" is not only mentioned by Suetonius and Aulus Gellius, but perhaps is alluded to in Ovid's fourth Epiftle:—

"His arcana notis terra pelagoque feruntur;"

which is paying this fpecies of fecret-writing a higher compliment than it would now be thought to merit: for, certainly, there is no great fkill required to decipher it; but the ancients had not then directed their attention particularly to this fubject, or they might have difcovered its imperfections.

The learned Montfaucon, in his "Palæographia Græca," lib. i. p. 36. edit. Paris, 1708, makes the following remark on the ftate of cryptography among the Greeks: "Κρυπτογραφίαν, five arcanum fcribendi modum, apud Græcos frequentatum obfervamus. Κρυπτογραφίαν vero duplici modo fieri deprehendimus, per commutationem fcilicet literarum, ac per novam & inufitatam characterum formam: utriufque fcribendi rationis alphabeta varia, cum exemplis exhibemus in fpeciminibus undecimi fæculi libro quarto; ubi quamplurima non minus fingularia, quam utilia & occulta, recenfebuntur." Accordingly, he gives, at pp. 87, 286, 288, various alphabets and fpecimens of occult writing, by tranfpofition or malformation of the common Greek letters; and efpecially as it was practifed by Amanuenfes in the eleventh and following centuries. It is certain, too, that the fame practice prevailed in much earlier times, even before the age of Æneas Tacticus; and, therefore, the Roman emperors moft probably learned this art from the Greeks. (Vide Palæographia Græca, l. iv. c. v. de Κρυπτογραφία.) But there is great reafon to believe, that all thefe ancient modes of writing were decipherable by the ordinary rules of analyfis in fuch cafes. We fhall, hereafter, point out the rules neceffary to be obferved in deciphering; and lay down a few directions for the application of common fenfe, where the fpecies of occult writing does not admit of any pofitive rule in its developement.

We have now carried our hiftory of this art down to a period, in which we take leave of the Greeks and Romans. Before we proceed, it may be expected that we fhould illuftrate thefe remarks by more examples: but, fince it would be very expenfive to the proprietors of the Cyclopædia, and no peculiar advantage to the inquifitive reader, if we were to engrave all the arbitrary characters with which fecret-writing has been performed, we fhall fubftitute in their place fuch marks and figures as are found in the printing-office; which will equally well illuftrate the principles and practice of the Greeks and Romans, in regard to the art of cryptography.

The methods of Julius Cæfar and Auguftus are too obvious to dwell upon: it is only required of the writer to put the fecond, third, fourth, or any other, letter of the alphabet, inftead of that which he generally writes; as in the words following, No. I. where we fubftitute the fourth letter for the firft, &c. viz.

No. I.

Multi, et pene infiniti, funt fcribendi modi.

Pxowl, hw fhqh lqilqlwl, vxqw vfulehqgl prgl.

In the fubfequent examples we ufe characters of different kinds in lieu of the common Roman letters. A fpecimen is compofed for each of the principal European languages, in all of which the fame mode of deciphering is applicable; for it is a matter of perfect indifference to a decipherer what form the characters affume, provided they anfwer (one for one) to the common alphabet, and are neither more nor lefs in quantity.

Ὑμεῖς ἔστε οἱ δικαιοῦντες ἑαυτοὺς ἐνώπιον τῶν ἀνθρώπων ὁ δὲ Θεὸς γινώσκει τὰς καρδίας ὑμῶν ὅτι τὸ ἐν ἀνθρώποις ὑψηλὸν βδέλυγμα ἐνώπιον τοῦ Θεοῦ ἔστιν ὁ νόμος καὶ οἱ προφῆται ἕως Ἰωάννου ἀπὸ τότε ἡ βασιλεία τοῦ Θεοῦ εὐαγγελίζεται καὶ πᾶς εἰς αὐτὴν βιάζεται.

In the beginning of the fifth century of the Christian æra, Pharamond, and other reigning princes, invented characters of singular forms ; and, during the eighth and ninth century, Charlemagne kept up a private correspondence with his agents in the north of Europe by similar modes of deception. Some of these alphabets, including that of Pharamond, are preserved by the noble duke Selenus, and by Trithemius. We have selected and exhibited (as a specimen of such inventions) one of those employed by Charlemagne, in *Plate* I. *figure* 1 ; under which is seen *fig.* 2. the form of another secret-alphabet, used in England during the reign of Alfred, copied from a MS. in the Bodleian library. (Vide "Astle's Origin and Progress of Writing, chap. vi. 2d edit. Lond. 1803.") Rudolphus IV. archduke of Austria, who lived in the 14th century, was also much versed in the practice of occult writing ; but there is no complete cryptographical work extant, of earlier date than that of Trithemius, composed under the sanction of Maximilian, at the end of the 15th century : soon after which period, Frederic II. Elector palatine, was induced, by a superstitious outcry against the author, of having practised diabolical mysteries, to commit the original MS. of Trithemius's curious book to the flames ! ! !

In *Plate* I. *fig.* 6, we have represented the cipher used by cardinal Wolsey, at the court of Vienna, in 1524.—*Fig.* 7, is the cipher which sir Thomas Smith employed at Paris, in 1563.—*Fig.* 8, is sir Thomas Chaloner's cipher from Madrid, in 1564.—*Fig.* 9, is that of sir Edward Stafford, from Madrid, in 1586. And, among the royal MSS. deposited in the British Museum, we have met with various other ciphers of the same period ; so that they had then become of general use in the different European courts.

The form of these ciphers, it will be observed, was very arbitrary and capricious : but the mode of secret-writing underwent

underwent a confiderable change in the next century, by the frequent adoption of arithmetical figures inftead of letters; as we perceive, for example, among the confidential epiftles of Charles I. to his fon. (Vide MSS. N° 132, and 6988 Bibl. Harl.) We fubjoin part of one of this unfortunate monarch's letters, dated Aug. 1ft, 1648, as a fpecimen of that kind of cryptography; and, for an explanation of many more of them, we refer to Dr. Wallis's unpublifhed collection in the Bodleian library at Oxford:

"I thought that 379 : 361 : 185 : 28 : 2 : 239 : 59 : 60 : 93 : 5 : 214 : 126 : 379 : 90 : 37 : 1 : 258 : 6 : 2 : 212 : 370 : 196 : 379 : 245 : 339 : 245 : 339 : 363 : 329 : 165 : 246 : 16 : 50 : 212 : 196 : 444 : 149 : 13 : 44 : 32 : 14 : 26 : 10 : 78 : 43 : 65 : 329 : 331 : 380 : 17 : 48 : 29 : 338 : 77 : 214 : 339 : 93 : 85 : 6 : 23 : 220 : 78 : 57 : 152 : 5 : 65 : I command you, &c."

In another letter, the king writes to his fon from Newport, (Nov. 7th, 1648,) and adds, "Let none decipher this but yourfelf, or my lord Culpeper;" fo that this cipher was, doubtlefs, regarded as very faithful, and was, perhaps, entrufted to only a few confidential perfons about his majefty. Somewhat prior to that critical time, however, we find Charles I. ufing a cipher which could by no means be depended on for fecrecy. We allude to an alphabet chiefly compofed of 24 fhort ftrokes, varioufly fituated upon a line; and by which, April 5th, 1646, he wrote to the earl of Glamorgan, afterwards the marquis of Worcefter. See Royal Letters, Bibl. Harl. vol. iii. 118, 119, &c.

We have exhibited this Ogham-like alphabet in *Plate* I. *fig.* 4. It has been often referred to of late, as a curious and very fimple invention. (See Biograph. Britan. vol. i. page 433, Art. Bales): and it was the accidental fight of this alphabet in the year 1804, which firft caufed the author of the prefent article to inveftigate the nature of ciphers; for, till then he had never once thought or read on the fubject. During the courfe of this examination, he difcovered (in Bibl. Harl. N° 2428.) the marquis of Worcefter's peculiar, and hitherto inexplicable, mode of writing; which feems to be briefly defcribed in the 3d and 4th of his lordfhip's "Centurie of Inventions:" of which, likewife, there is in the Britifh Mufeum a fair manufcript copy, dated "from Auguft ye 29th, to Sept. ye 21th, 1659."

We here extract the marquis's words regarding this cipher, from pages 5th and 6th of his "Inventions;" which were firft written by him in 1655, but not printed till 1663, as we learn from the work itfelf. "A cypher and character fo contrived, that one line, without returns and circumflexes, ftands for each and every of the 24 letters; and as ready to be made for the one letter as the other."

"This invention, fo refined and fo abbreviated, that a point only fheweth diftinctly and fignificantly any of the 24 letters; and thefe very points to be made with two pens, fo that no time will be loft; but, as one finger rifeth, the other may make the following letter; never clogging the memory with feveral figures for words and combinations of letters; which, with eafe and void of confufion, are thus fpeedily and punctually, letter for letter, fet down by naked and not multiplied points. And nothing can be lefs than a point; the mathematical definition of it being, *Cujus pars nulla*. And a motion no fwifter imaginable than *femiquavers* or *relifhes*, yet applicable to this manner of writing."

This cipher was one of the extraordinary inventions for which the marquis applied to parliament, in hopes of a remuneration; but as he was not known to have either printed an account of it, or to have left any explanation of it in writing, many fhrewd conjectures were afterwards made touching the nature of this noble author's contrivance. We fhall notice one of thefe gueffes, before we proceed to give a farther defcription of it. (See Gent. Magazine, vol. xviii. p. 55.) An anonymous gentleman propofes "to rule his paper with quarternions of lines, as if for mufic, and to let the points reprefenting the letters be placed on, or between thefe lines; one-half of the alphabet to afcend in the fcale, and to be done with common ink; the other half to defcend, and to be done with red ink; the red ink pen in one hand, and the black in the other." The propofal, however, does not at all correfpond with what we believe to have been intended by the marquis of Worcefter: it is alfo much too complex and tedious for ordinary practice, and would be far from anfwering the purpofes of a faithful cipher.

As this nobleman was one of the moft ingenious and extraordinary perfonages of his time, and may even be confidered as a prodigy in mechanical aquirements, we take the liberty of ftating all we know of his difcoveries in fecret writing; partly divulged by himfelf, in his very fcarce volume of "Inventions;" and partly collected from a MS. in the Harleian Library, No. 2428, which bears clear internal marks of its origin, although it was not fuppofed to be his, until we lately convinced the Librarian. "The one-line cypher" and mode of dot-writing are thus entitled, in the above manufcript: "An explanation of the moft exact and moft compendious way of fhort writing; and an example given by way of queftions and refolves upon each fignificant point, proving how and why it ftands for fuch and fuch a letter, in order alphabetically placed in every page."—His method of writing is fhewn in *fig.* 5. *Plate* I. An engraved page is given to write upon, in which are made horizontal rows of octangular fquares or chequers; and a ftrait line is to be drawn from the centre towards the circumference of thefe fquares, in different pofitions and of various lengths, for each letter of the alphabet. Thus *A* is a fhort horizontal ftroke, made to the right hand, and not touching the circumference; *I* is the fame ftroke paffing clofe to the circumference; *R* is the fame ftroke, going beyond the circumference; *E*, *N*, and *W*, are reprefented by a fimilar ftroke, in the oppofite direction, but varying in their lengths. By a like method, he fuggefts that we may write with a dot or fingle point only; which is to be placed at a certain diftance, and in a certain direction, from the centre of the octagon, for each letter of the alphabet.

The Marquis propofes this contrivance for the purpofe of writing with fecrecy, as well as with brevity; and leaves it to the will of any perfon to change the value or name of the letters, as it may fuit his fancy or intention: "The points to be written," fays he, "and reade as they precede or as they are the one above the other;" and for the fake of expedition as well as "for hufbanding of paper," he advifes "to omit all needleffe and unfounding letters," as we do in fhort-hand writing.

This ingenious plan is better adapted for fecret writing, than for fhort-hand; and yet we do not think it would be difficult to decipher any thing written in this way, unlefs the writer were to change the power of his letters very frequently, becaufe he would not otherwife be able to elude the common rules for deciphering.

That the Marquis had turned his attention particularly to this fubject, is ftrikingly evident from the following paffages, contained in his very curious book; entitled, — "A Centurie of the Names and Scantlings of Inventions by me already practiced."

No. 5. "A way by a circular motion, either along a rule or ring-wife, to vary any alphabet, even this of points; fo that the felf-fame point individually placed, without the leaft additional mark or variation of place, fhall ftand for

for all the 24 letters, and not for the fame letter twice in ten fheets writing; yet as eafily and certainly read and known as if it ftood but for one and the felf-fame letter conftantly fignified."

No. 6. "How at a window, as far as eye can difcover black from white, a man may hold difcourfe with his correfpondent, without noife made or notice taken; being according to occafion given and means afforded, *ex re natâ*, and no need of provifion before hand; though much better if forfeen, and means prepared for it, and a premeditated courfe taken by mutual confent of parties."

No. 7. "A way to do it by night as well as by day, though as dark as pitch is black."

No. 32. "How to compofe an univerfal character methodical and eafie to be written, yet intelligible in any language; fo that if an Englifhman write it in Englifh, a French-man, Italian, Spaniard, Irifh, Welfh, being fcollars, yea, Grecian or Hebritian, fhall as perfectly underftand it in their owne tongue, as if they were perfect Englifh; diftinguifhing the verbs from nouns, the numbers, tenfes, and cafes as properly expreffed in their own language as it was written in Englifh."

No. 33. "To write with a needle and thred, white or any colour upon white, or any other colour; fo that one ftitch fhall fignificantly fhew any letter, and as readily and as eafily fhew the one letter as the other, and fit for any language."

No. 34. "To write by a knotted filk ftring, fo that every knot fhall fignify any letter, with comma, full point, or interrogation, and as legible as with pen and ink upon white paper."

No. 35. "The like by the fringe of gloves."

No. 36. "By ftringing of bracelets."

No. 37. "Pinck'd gloves."

No. 38. "By holes in the bottom of a fieve."

No. 39. "By a lattin or plate lanthorn."

Nos. { 40. "By the fmell." 41. "By the tafte." 42. "By the touch." } "And by thefe three fenfes as perfectly, diftinctly, and unconfufedly, yea as readily, as by the fight."

No. 43. "How to vary each of thefe, fo that ten thoufand may know them, and yet keep the underftanding-part from any but their correfpondent."

No. 51. "A rule of gradation, which, with eafe and method, reduceth all things to a private correfpondence, moft ufeful for fecret intelligence."

No. 52. "How to fignify words and a perfect difcourfe by jangling of bells of any parifh-church, or by any mufical inftrument within hearing; in a feeming way of tuning it, or of an unfkilful beginner."

No. 75. "How a tape or ribbon-weaver may fet down a whole difcourfe, without knowing a letter, or interweaving any thing fufpicious of other fecret than a new-fafhion ribbon."

No. 76. "How to write in the dark as ftraight as by day light."

Our limits, for this article, do not allow us to enter into the merits of every propofal made public, for fecret correfpondence: but, having before obferved that arithmetical figures had become very common in the reign of Charles I. inftead of the ciphers previoufly employed, we fhall here offer a few remarks on their ufe. The celebrated and profound mathematician, Dr. Wallis, deciphered a great number of intercepted letters, written in figures, about the period of that King's unhappy controverfy. We have already faid, that copies of thefe deciphered papers are depofited in the Bodleian library, at Oxford; and in the prefatory obfervations to that collection, Dr. Wallis declares his judgment of them in thefe words: "I would not defire to ufe a better cipher than moft of thofe * * * *. I do fcarcely believe that it will be an eafy matter to contrive a way more intricate than the *figure-cipher*, ordinarily now in practice, with the like convenience for ufe: and, if any affect fome more perplexed than thefe, I doubt not but his fuppofed better way will be equally obnoxious to a difcovery; or elfe will be extremely tedious in ufe, both to him that writes by it, and to him that is to read it, that it will not admit of any tolerable difpatch." (See alfo Mr. Davy's Effay on Deciphering, p. 17.—General Dictionary, vol. x. p. 93; and Biographia Britannica, Art. *Wallis*.) This acute author was very different from Scaliger, in his opinion of fecret writing: for, while the latter ridiculed the idea of infcribing what could never be developed, becaufe he was able to decipher the Lacedæmonian Scytale; Dr. Wallis, on the contrary, who had gone fifty times deeper in this fcience than Scaliger, admits "there may be a cipher fo intricate as fhall be beyond the art of man to difclofe."

No perfon except Vieta, (a French mathematician, who was employed by Francis I.) had difcovered near fo much fkill in deciphering, as Dr. Wallis. He feems not to have known of what Vieta did in this way, nor had he any aid from other perfons in his refearches: we are, therefore, difpofed to pay the greateft deference to his judgment as a decipherer; but we beg leave to obferve, that it does not follow he fhould know all the poffibilities of this multiform art. He confidered the "figure-cipher" as extremely intricate; we doubt not, that others may be contrived equally fo; and that fuperadded to this quality, a cipher may be adapted for greater difpatch, "both to him that writes by it and to him that is to read it." Befides which, we think it even practicable to invent a cipher, exclufive of its having thofe properties, which fhall not be much expofed to fufpicion; and this, we conceive with Lord Bacon, to be a very effential requifite in certain fituations of the writer and reader, though not fo in all circumftances.

There is a method of employing figures, common enough in the prefent day, which was much recommended by Baptift Porta and Cardanus; and therefore not a novel invention: but Blaife de Vigenere, whofe treatife on ciphers was publifhed at Paris in 1587, has pointed out the inconveniences of this method; which confifts in referring to words or fentences by the correfponding pages and lines of fome rare printed book, in the poffeffion of the confederate parties. Now, fays Vigenere, (p. 208.) this plan is too laborious, and flow in operation, for bufinefs requiring to be defcribed in detail; it will not always provide the words fought for, at leaft without an immenfe deal of pains, perhaps after examining through fome hundred pages; and, unlefs a dictionary be ufed, the names of perfons, places, or profeffions, can be found in no book whatever: befides which, many accidents may lead to a difcovery of the key or book fo confided in; and many others may happen to deprive us of that refource, or to render it inconvenient to depend on fuch a ftratagem. The writing, moreover, is always liable to fufpicion, if intercepted. So that this plan is wholly unfit for extenfive correfpondence, as in diplomatic affairs; and ought rather to be accounted a childifh than a fcientific invention, however it has been fanctioned by modern practice, among military commanders and officers of ftate.

We do not object altogether againft the ufe of figures and numeral characters, as if they were unfit, *on account of their form*, to be adopted in cryptographical writing; but we object to the above manner of applying them, becaufe as numerals,

rals, denoting only the pages or lines of a book, theſe figures cannot be written with any tolerable expedition, and muſt be a perpetual check to the reader's progreſs in deciphering. This method, it muſt be acknowledged, poſſeſſes the property of being undecipherable without the key: for, let us ſuppoſe (in writing the example given by Mr. Thickneſſe) "That the parties agree to correſpond by Newton's firſt edition of Milton; and thereby direct each other, in their letters, to ſuch a page, ſuch a line, and ſuch a word; it may be aſked, Who would be able to find out, that their writing page 7, line 2, words 3, 4, 5, and vol. ii. page 8, line 19, word 4, —the ſame page, line 9, words 3, 4, and 5—was to ſay 'The weſtern empire is degenerated into licentiouſneſs?' without being told that theſe words will be found in the firſt and ſecond volume of Farneworth's tranſlation of Machiavel's works: the firſt three words from his hiſtory of Florence, and the remainder from his political diſcourſes on the firſt Decad of Livy." All this will be granted; but as the property of being intricate is not the only one we ſhould look for in a good cipher, we conclude again by obſerving, that the above plan is puerile and unſcientific to the laſt degree; conſequently, that it is wholly unfit for men of buſineſs, or for any beſides incidental occaſions, where very little writing is required.

By referring to a dictionary, indeed, theſe objections are partly leſſened, becauſe the words may be found with greater facility than in other books; but even ſuch a reſource is very inſufficient for all occaſions, and it ſtill muſt prove a moſt tedious and operoſe employment, in writing only ten or a dozen lines. The French Encyclopédiſts deſcribe a much more feaſible mode of writing by figures, which, nevertheleſs, we cannot approve as the beſt method of cyphering. It is this:

The correſpondents agree on a ſet of figures to repreſent all the letters of the alphabet, and alſo a great many words or phraſes. Several ways may be adopted for the repreſentation of any important letter, or phraſe, of frequent occurrence; ſuch as the five vowels, or the words France, emperor, king of this and that nation, ſtates-general, cardinal ſo and ſo, the allied armies, an ambaſſador's name, &c. &c. &c. All theſe different words are to be claſſed and arranged in ſuch a manner as to be eaſily found, both in writing and deciphering; and another claſſification muſt be made, in which the figures ſtand firſt, and the words in an oppoſite column. The ſentences and entire paragraphs, which are of prime importance in a diſpatch, ſhould be written wholly in cipher, without any intermixture of common letters; becauſe, by the aid of particles and connecting words, the terms of greater conſequence, on which the ſenſe hinges, will often be diſcovered, and the matter in debate or agitation will thus be underſtood. It is alſo proper to write the lines ſo far apart, that the decipherer may ſubſcribe the figures when he reads the diſpatch; as in the following ſpecimens:

Le miniſtre d'ici eſt tout dévoué aux intérêts de la France:
102 25 44 9 1200 70 350 888
c'eſt le fruit de dix mille Louïs ſemées à propos.
54 5 20 60 101 19 501 80
The negociation is interrupted by the pertinacity and
2 999 4 10 50 1000 14
unreaſonableneſs of the duke, who probably has received
350 31 86 5 77 680
private inſtructions from his court.
1110 21 89 231

Means may be deviſed for detecting the unfaithfulneſs of a ſubordinate ſecretary, who is ſuppoſed to have communicated his cipher to a foreign power. The court may demand of its miniſter abroad, or the miniſter require of his court, ſomething quite the reverſe of what is deſired, it being previouſly agreed by the cabinet that a certain mark or private ſign denotes oppoſition or annihilation, with reſpect to the particular thing annexed to the ſaid ſign. This ſpecial mark may be called the annulling ſign, and will ſerve for various important uſes; as has often been proved in conducting naval ſignals, where the enemy was within ſight, or where any miſtake happened to ariſe in the courſe of a correſpondence. By the help of ſuch an artifice, when a cipher has been accidentally diſcovered, or traitorouſly diſcloſed, a ſkilful negociator will be able to deceive the enemy, and lead him into inextricable errors, which may finally turn to the advantage of his own cauſe.

Sir J. Ware, colonel Vallancey, and Mr. Aſtle give remarkable accounts of the Iriſh ſteganography, by means of peculiar alphabets, called by the barbarous name of Ogums, or Oghams, of which there are three kinds: the firſt is compoſed of ſtrokes and marks, that derive their power from certain poſitions with reſpect to one horizontal line, over, or under, or upon, which they are drawn; this principal line ſerving for a rule or guide, its upper part being named the left, and its under part the right. The characters or ſhort ſtrokes, by their number or ſituation, repreſent, not only ſingle vowels and conſonants, but alſo diphthongs and triphthongs.

In our *Plate* I. *fig.* 3. is ſeen one of the moſt ſimple Oghams, copied from Sir J. Ware's "Antiquities of Ireland" (vol. ii. p. 20.), which would not be very difficult to decipher; becauſe, although the number of diagonal and perpendicular marks is conſiderable, it muſt be obvious how many of them repreſent one letter, and it will be ſeen that they make up but twenty-ſix in all. The marks for diphthongs and triphthongs do not occur in ancient manuſcripts, the vowels being repreſented ſingly, as *ae*, not *æ*, &c. Therefore an Ogham having diphthongs, ſuch as that we have ſelected, cannot be regarded as of ancient date.

The ſecond and third kinds of Ogham uſed by the Iriſh differ chiefly in this: that the letter *b* or *c* is placed firſt, inſtead of *a*; or, that the mark for one of thoſe letters is ſubſtituted for all the vowels, by doubling or reverſing it, and by its frequent repetition, ſo as to confuſe the writing. (See "Tractatus apud Hibernos veteres, de occultis ſcribendi formulis, ſeu Artificiis Hibernicè Ogum dictis;" a MS. lately given to the Britiſh Muſeum by the Rev. Dr. Miller.)

Several ſpecimens of Iriſh Oghams are engraved in the ſecond edition of Mr. Aſtle's Hiſtory of Writing; a work replete with intereſting matter on various points connected with that ſubject in general, but extremely deficient on ſhort-writing (ſtenography), and ſecret-writing (cryptography). Upon theſe two departments of the art, we feel a deſire, if opportunity ſhould permit, of laying before the public ſome reſults of our own inveſtigations and practice; though we cannot indulge the vain opinion of our feeble efforts, which Trithemius entertained of his learned labours: (Præf. ad Maximil. Imperatorem, Polygr. p. 100.) "In manibus jam habeo grande opus, quod ſi unquam fuerit publicatum, totus mundus mirabitur." See the article STENOGRAPHY.

It might be thought an injuſtice to the memory of the profound and noble chancellor Bacon, not to ſtate in detail whatever his lordſhip has written upon ciphers; as ſome men of acknowledged ability (for inſtance, biſhop Wilkins and Mr. Falconer), have conſidered his propoſal ſuperior to every other. Mr. Falconer calls it "the moſt ingenious method extant;" and the biſhop of Cheſter ſays, "This way of writing is juſtly to be preferred before any other, as contain-

 ing

ing in it more eminently all thoſe conditions that are deſirable in ſuch kind of inventions, viz.

" 1. 'Tis not very laborious either to read or write.
" 2. 'Tis very difficult to be deciphered.
" 3. 'Tis void of ſuſpicion."

We find alſo the following encomium in Mr. Thickneſſe's Treatiſe; "Thoſe who are acquainted with lord Bacon's great depth of capacity, will readily agree with me that a ſecret method of writing contrived by a man of his amazing penetration, muſt be ſuperior to all others, as indeed it is, and contains the higheſt degree of cypher."

We copy the illuſtrious Verulam's own propoſal, out of Dr. Shaw's edition of his works, vol. i. p. 141—145.

"There are ſeveral kinds of cyphers; as the *ſimple;* thoſe mixed with non-ſignificants; thoſe conſiſting of two kinds of characters; *wheel-cyphers, key-cyphers, word-cyphers,* &c. There are three properties required in cyphers, viz.; (1.) that they be eaſy to write and read; (2.) that they be truſty and undecypherable; and, (3.) if poſſible, clear of ſuſpicion. For, if a letter ſhould come into the hands of ſuch as have a power over the writer, or receiver, tho' the cypher itſelf be truſty, and impoſſible to decypher, 'tis ſtill ſubject to examination and queſtion; unleſs there be no room to ſuſpect or examine it.

" There is a new and uſeful invention, to elude the examination of a cypher, viz.; to have two alphabets, the one of ſignificant, and the other of non-ſignificant letters; and folding up two writings together; the one conveying the ſecret, whilſt the other is ſuch as the writer might probably ſend without danger. In caſe of a ſtrict examination about the cypher, the bearer is to produce the non-ſignificant alphabet for the true; and the true for the non-ſignificant: by which means the examiner would fall upon the outward writing; and finding it probable, ſuſpect nothing of the inner.

" But to prevent all ſuſpicion, we ſhall here annex a cypher of our own, which has the higheſt perfection of a cypher; that of ſignifying omnia per omnia; any thing by every thing; provided only the matter included be five times leſs than that which includes it; without any other condition or limitation. The invention is this; firſt let all the letters of the alphabet be reſolved into two only, by repetition and tranſpoſition: for a tranſpoſition of two letters, thro' five places, or different arrangements, will denote two and thirty differences; and conſequently fewer, or four and twenty, the number of letters in our alphabet; as in the following example:

" A biliteral alphabet, conſiſting only of *a* and *b* changed through five places, ſo as to repreſent all the letters of the common alphabet.

A = aaaaa	I = abaaa	R = baaaa
B = aaaab	K = abaab	S = baaab
C = aaaba	L = ababa	T = baaba
D = aaabb	M = ababb	V = baabb
E = aabaa	N = abbaa	W = babaa
F = aabab	O = abbab	X = babab
G = aabba	P = abbba	Y = babba
H = aabbb	Q = abbbb	Z = babbb

" Thus, in order to write an *A*, you write five *a's*, or aaaaa; and to write a *B*, you write four *a's*, and one *b*, or aaaab; and ſo of the reſt.

" And here, by the way, we gain no ſmall advantage; as this contrivance ſhews a method of expreſſing, and ſignifying one's mind, to any diſtance, by objects that are either viſible or audible; provided only the objects are but capable of two differences; as bells, ſpeaking-trumpets, fire-works, cannon, &c. But for writing, let the included letter be reſolved into this biliteral alphabet: ſuppoſe that letter were the word *Fly*; it is thus reſolved:

F	L	Y.
aabab	ababa	babba.

" Let there be alſo at hand two other common alphabets, differing only from each other in the make of their letters, ſo that, as well the capital as the ſmall be differently ſhaped, or cut, at every one's diſcretion: as thus for example, in Roman and Italick; each Roman letter conſtantly repreſenting A, and each Italick letter *B*.

" The firſt, or Roman Alphabet.

A, a.	K, k.	T, t.
B, b.	L, l.	V, v.
C, c.	M, m.	U, u.
D, d.	N, n.	W, w.
E, e.	O, o.	X, x.
F, f.	P, p.	Y, y.
G, g.	Q, q.	Z, z.
H, h.	R, r.	
I, i.	S, s.	

All the letters of this Roman Alphabet are read, or decyphered, by tranſlating them into the letter A, only.

" The ſecond, or Italick Alphabet.

A, a.	*K, k.*	*T, t.*
B, b.	*L, l.*	*V, v.*
C, c.	*M, m.*	*U, u.*
D, d.	*N, n.*	*W, w.*
E, e.	*O, o.*	*X, x.*
F, f.	*P, p.*	*Y, y.*
G, g.	*Q, q.*	*Z, z.*
H, h.	*R, r.*	
I, i.	*S, s.*	

" All the letters of this Italick alphabet are read by tranſlating them into the letter *B*, only.

" Now adjuſt or fit any external double-faced writing, letter by letter, to the internal writing, firſt made biliterate; and afterwards write it down for the letter, or epiſtle, to be ſent. Suppoſe the external writing were, *Stay till I come to you;* and the internal one were *Fly;* then, as we ſaw above, the word *Fly*, reſolved by means of the biliteral alphabet, is

F	L	Y
aabab	ababa	babba,

whereto I fit, letter by letter, the words, *Stay till I come to you;* obſerving the uſe of my two alphabets of differently ſhaped letters: thus,

aabab ababa babba
St*ayt* i*l* i co *me to* you.

" Having now adjuſted my writing, according to all my alphabets, I ſend it to my correſpondent; who reads the ſecret meaning, by tranſlating the Roman letters into *a's*, and the Italick ones into *b's*, according to the Roman and Italick

Italick alphabets; and comparing each combination of five of them with the biliteral alphabet.

"This doctrine of cyphers has introduced another, relative to it; viz. the art of decyphering, without the alphabet of the cypher, or knowing the rules whereby it was formed. This indeed is a work of labour and ingenuity, devoted, as well as the former, to the secret service of princes. Yet, by a diligent precaution, it may be render'd useless; tho', as matters now stand, 'tis highly serviceable. For, if the cyphers in use were good and trusty, several of them would absolutely elude the labour of the decypherer; and yet remain commodious enough, so as to be readily wrote and read: but through the ignorance and unskilfulness of secretaries and clerks, in the courts of princes, the most important affairs are generally committed to weak and treacherous cyphers."

It becomes us to offer our opinion with extreme diffidence, in presuming to criticise the production of a man so highly distinguished for his capacity and acuteness. But we cannot refrain from believing, that this contrivance of lord Bacon will appear to most persons too operose and slow of execution for public business; of which, indeed, we desire no better proof, than that it has met with so little encouragement from official and regular practice. It must always be deemed a serious inconvenience attending his lordship's plan, that it requires, at least, five times more labour than is requisite in ordinary writing. Whereas, if a triformed alphabet were to be invented in lieu of this, and regulated by another alphabet composed of three letters instead of two, the secret writing would then bear only a triple proportion to common writing, and the trouble of an amanuensis might thus be greatly diminished.

A second point on which we beg leave to express our doubts, is, Whether this cipher be infallibly secure against the scrutinizing eye of a diligent examiner? For, if the reader were to place a mark of distinction between every fifth character, reckoning the five as one letter, we ask, Why might not this writing be liable to a discovery as well as any simple cipher, and on the same general principles? Nay, Mr. Falconer himself confesses it may, notwithstanding the compliment he pays to the noble author for his ingenuity and learning. Nevertheless, we think it will be granted on all hands, that lord Bacon's mode, if it had not been published, would have possessed one rare and valuable property, beyond the ciphers previously invented, namely, that of being scarcely at all exposed to suspicion; and therefore, in this respect, it is entitled to especial attention and praise.

Bishop Wilkins avails himself of the fact, that two signs repeated, as in lord Bacon's alphabet, or three combined in a certain order, will serve to communicate our thoughts; and he improves upon it in the following manner: Let there be two bells of different notes, or one bell and some other loud sound, as that of a musket, horn, drum, &c. According to the plan of a biliteral alphabet, a man may express any letter by two such different sounds, repeating them five times. But if the sounds were capable of a triple difference, then each letter may be expressed by a threefold sound; and if they contain a quintuple difference, or consisted of five sounding instruments, every letter might be signified by two of them only; as we have shewn already with two flambeaux, and as will be further obvious from our subsequent remarks.

He quotes a story from John Baptist Porta, in lib. i. cap. 6. of his work, "De Furtivis Literarum Notis, vulgo de Ziferis," who relates, that when the citizens at the siege of Navarre were reduced to the greatest extremity, they communicated their wants to their distant friends by discharging various kinds of cannon in the night time, according to a predetermined order; by which means they obtained such supplies as they needed, and preserved their city. But the most curious proposal for the management of sounds in correspondence, is that of expressing letters and words by the ordinary notes of a musical instrument; which bishop Wilkins believed might be adapted "for a universal language, and the writing of them for a universal character," not by expressing words, "but things and notions." Then, says he, "there might be such a general language as should be equally speakable by all nations and people."

We are not sanguine enough to expect the learned bishop's plan, of recovering the world from the Babel-confusion, will very quickly take effect; and, certainly, the specimen of musical writing which he has exhibited is very unlikely to answer that purpose. Mr. Thicknesse thinks, "writing performed by an harmonic alphabet would be the most void of suspicion of all others:" both he and the bishop have therefore given an alphabet of this kind, and they both presume on his lordship being "the only writer who has mentioned the method of writing by musical notes;" wherein, however, they are both mistaken. For Augustus, the duke of Brunswick (*alias* Gustavus Selenus,) in his "System of Cryptography," lib. vi. cap. 19. exhibits various specimens of writing in that way; and does not claim the invention himself, but ascribes it to count Frederic of Oetingen. Nay, it is pretty clear that Trithemius was not ignorant of this device; since he declares, in his epistle to Bostius, A. D. 1499, that he could discourse by playing on the organ or singing, "ludendum in organo vel cantandum," which seems to be the proposal above mentioned, or something very like it.

That we may not appear to have slighted so curious a proposal, we will offer a few remarks on this subject; and beg our readers to consult *Plate* II. *figs.* 2, 3, 4, and 5; where we have given an harmonic alphabet, and several specimens of musical writing, in illustration of the present article.

If four or five characters be amply sufficient, by combination and repetition, to denote every word or idea we can express, it is certain that seven musical sounds are more than sufficient for the same purpose. But we must learn to distinguish between these sounds, as they would be represented in ordinary writing, and the scientific arrangement of them, so as to form a musical composition: for those two results may happen to be as different from each other, as the chattering of a magpie and the orations of Cicero, or as the jumbling of letters in a box, and the adjustment of them by a typographer.

It is true that the seven musical notes are enough in respect to number, (for seven notes will afford 5040 varieties or combinations, without repeating any of them); but we are not therefore to conclude, that they can be made to coalesce and harmonize, according to the precise order and relation we should wish to use them in alphabetical writing.

Articulate sounds are represented on paper, &c. by certain substitutes called letters, which possess whatever quality we may choose to impose on them: but harmonic tones are not at all controulable by arbitrary laws; their inherent powers are fixed by nature; they cannot, therefore, be made subservient to our pre-conceived methods of speech, or our established notation by letters; and, if they are compelled to associate with these, it must be managed by the subversion of our common language, and adapting its structure to the natural qualities of musical sounds. This being our opinion, we should as soon expect a man to converse in two

two different languages at once, or the wind to blow in two opposite directions, as the laws of harmony to obey any existing plans of articulation and writing. See the article HARMONY.

Having thus freely given our deliberate view of this subject, we lay before the reader some observations of Mr. Philip Thicknesse, who has laboured more earnestly than any other author to enlist the powers of harmony into the service of cryptographers. As his opinion differs from our own, we do him the justice to adduce his words at full length. In the specimens of musical composition, however, we have corrected several of that gentleman's errors; so that his remarks will not suffer any loss, from our officiousness.

"Bishop Wilkins, in his chapter relative to a language consisting of tunes and musical notes, without any articulate sound, says, 'If the musical instrument that is used for this purpose, be able to express the ordinary notes, not only according to their different tones, but their times also, then may each letter of the alphabet be rendered by a single sound; whence it will follow, that a man may frame a language, consisting only of tunes, and such inarticulate sounds, as no letters can express, which kind of speech is fancied to be usual amongst the lunary inhabitants; who, as Domingo Gonsales hath discovered, have contrived the letters of the alphabet upon the notes after some such order.' But the specimen the bishop has given, (by writing *Gloria Deo soli* by minums, on musical lines,) will instantly appear to any one the least conversant with music, that being without harmony or time, it must have no meaning, or that some hidden matter is thereby disguised. I shall therefore endeavour to write down an alphabet by musical notes, in such a manner, that even a master of music shall not suspect it is to convey any meaning, but that which is obvious; and I am persuaded an alphabet of musical notes may be so contrived, that the notes shall not only convey the harmony, but the very words of the song, so that a music-master, (which is too often his design) may instruct his female pupil, not only how to play upon an instrument, but how to play the fool at the same time, and impose upon her parents or guardians, by hearkening to his folly, impertinence, and wickedness. When a music-master has once taught his female pupil to understand a musical alphabet, and she will permit him to carry on a secret correspondence, he may send her daily a lesson which she may repent having learned as long as she lives.

"In the plate annexed, I have given a musical alphabet (*Plate* II. *fig.* 2.), and under it a specimen to explain more fully my meaning (See *Plate* II. *fig.* 3.). If a music master be required to play it, he will certainly think it an odd, as well as a very indifferent composition; but neither he, nor any other person, will suspect that the notes convey also the two following harmonious lines from Dr. Goldsmith's "Deserted Village:"

> 'Near yonder copse where once the garden smil'd,
> And still where many a garden-flow'r grows wild.'

"Now, it may be so ordered, that the plain notes, *i. e.* the crotchets and minums alone, compose the alphabet, and that neither flats nor sharps, nor the smaller notes between, (which may be placed as mere graces, and meant to deceive) have any thing to do with the reading; so that the decypherer would not so readily know how to proceed, and many people there are, who will think it impossible to be made out without the key; yet I am persuaded, one who possesses a very moderate turn for such business, would read it in a very short time.

"If the words of a song could be thus conveyed by the notes, as well as the air, it would, exclusive of the contrivance, be of infinite service and ease to ladies who sing: indeed, it seems, to those who are not acquainted with music, almost inconceivable, how a person at first sight, shall be able to read the bass and treble cliff, together with the words, and play two parts and sing one, at the same time. It is certain that two musicians might, by a very little application, carry on a correspondence with their instruments: they are all in possession of the seven notes which express *a, b, c, d, e, f, g;* and know by ear exactly when either of those notes are toned; and they are only to settle a correspondence of tones for the remaining part of the alphabet: and thus, a little practice might enable two fiddlers to carry on a correspondence, which would greatly astonish those who did not know how the matter was conducted. Indeed, this is no more than what is called *dactylogy*, or *talking on the fingers*, which I have seen done, and understood as quick, and readily almost, as common conversation.

"A secret correspondence may be carried on by musical notes, or by communicating the words of a song, by the same vehicle which points out the time and harmony, and this may be done (without having any knowledge of musical compositions) by any common piece of music whatever. To do this an alphabet must be formed, as in *Plate* II. *fig.* 2, or in any other manner; for it may be contrived much better for the purpose.

"Then take any piece of music (but such as is composed of the greatest variety of notes will be best) and copy it out upon ruled music paper, leaving one row of blank lines between, *i. e.* those lines on which the second or bass is usually written. When you have copied the whole out, draw straight lines on the bass cliff, exactly under those which divide the time in the treble. Suppose you would write, 'My time, O ye Muses,' &c. look for the note which is *m* in your alphabet, and then for *y;* now, suppose there are eight or ten notes between the *m* and the *y*, then those are to be marked as nulls on the bass cliff, just under each note, by that mark which in music imports a rest, which is this ㄱ, and the confederate who has the key, knowing that the rest-notes are nulls, only makes use of those which are open, or which may be pointed out, by inserting other notes exactly under them in the bass cliff: and if the under notes are placed three notes lower on the lines than those in the treble are, they will in that case be in harmony, and the rests between, being in such an order, will prevent any suspicion, except to those who understand music; and yet even those who do, would hardly suspect that the notes of lady Coventry's minuet implied, as it might, an assignation in Grosvenor-square: or, instead of the rests being under the nulls, as they will of course be very frequently, they might be placed only under those notes which convey the reading, and then the bass cliff would appear as busy as the treble, and tend the more to perplex the decipherer, as he could not be sure, but both lines were employed to conceal the private writing; indeed where letters fall very distant from each other in the treble, it might be supplied, and frequently too, on the bass cliff, and signified by a dot, or some other musical character, placed near the treble, more immediately above it. A letter thus written in cipher would disconcert even a good decipherer, and throw him out of the methodical way of coming at the secret contents: indeed, I rather think it must be come at more from ingenuity than method.

"This, however, is a hint only, how this kind of cipher may be completely made use of, rather than a perfect method; but I am persuaded, that a good composer of music would be able to write any common epistle, with the assistance of the treble and bass cliff, so as to have very few null-

 notes;

notes; and the ſecret meaning inſtantly obtained by thoſe who are in poſſeſſion of the harmonic alphabet. Or, ſuppoſe every crotchet or minum, which is to expreſs a letter, is written with the tail of the note downwards, and all the nulls upwards; this indeed, might occaſion ſome awkwardneſs in the appearance of the muſic, but it would not tend at all to a diſcovery: but ſtill, what I think practicable is, that an harmonic alphabet may be ſo contrived by a good compoſer of muſic, that every note ſhall be expreſſive of a letter, and convey the words of the ſong as perfectly to the eye, as they do the harmony to the ear. The compoſer of an harmonic alphabet, ſhould be careful to include thoſe notes which are moſt frequently uſed, into his alphabet; and thoſe, I think, are on or between the five ruled muſic lines; but he muſt carefully avoid having any of thoſe notes, already ſo well known, to expreſs *a*, *b*, *c*, *d*, *e*, *f*, *g*, keeping their proper place; for that would be the firſt conſideration of an ingenious decipherer.

"Now, if this art of writing ſecretly by muſical notes, was to be practiſed, I queſtion whether a decipherer, to be expert in his art, muſt not only be a maſter of languages, but even a diſciple of Apollo. However, according to the muſical alphabet annexed, provided a letter is written by it, and the active notes well corded between with nulls, upon the ſame lines, which might be known to be ſuch, by the tail being turned up or down, or characterized by the mark for a beat, a ſhake, a trill, a pauſe, a flat, or a ſharp, it would be ſcarce poſſible for a decipherer to make out, with certainty, the ſenſe; and this method, unpubliſhed, would be leaſt liable to ſuſpicion; for who, that examined a ſuſpected meſſenger, would think an old ſong, without words, in which perhaps the meſſenger's tobacco or ſnuff might be put, contained the ſecret he was to convey? Nor could an ordinary meſſenger, either by bribes or threats, diſcover any thing more, than that the bearer was ſtrictly charged to deliver that piece of muſic, into which he puts his tobacco, to ſuch a particular perſon.

"It may ſeem at firſt difficult to remember what letters the notes imply, and I ſhould have thought ſo too, had not the making out of the alphabet only, impreſſed my mind with the remembrance of every letter; and yet I cannot boaſt of having a good memory; but upon trying the experiment in my family, I find that it is attainable, by writing them down two or three times, without any farther trouble. Indeed, to remember a name, or a word, it is beſt done by writing it down, though it be only with the finger upon a table, without any mark, as the having turned the form of the letters by the hand, will greatly aſſiſt the memory.

"Biſhop Wilkins thinks it poſſible, that if inarticulate ſounds can be contrived, to expreſs not only letters and words, but things and notions, then there might be ſuch a general language formed, as might be equally ſpeakable by men of all nations, and ſo reſtore to us what we loſt by the ſecond general curſe; which is yet manifeſted unto us, he ſays, not only in the confuſion of writing, but alſo in ſpeech. But I am apprehenſive this univerſal language may ſleep quietly with the "flying chariot," the ſame author was once ſo buſy in conſtructing.

"In the ſpecimen given (on *Plate* II. *fig.* 3.) of ſecret writing by the harmonic alphabet, it muſt be obſerved, that every note implies a letter alſo; and, conſequently, under ſuch a reſtraint, it can only have the appearance, and be the picture of muſic without the harmony: yet it is ſuch a picture as muſt paſs unſuſpected by all who do not underſtand muſic perfectly, and by many who do; at leaſt thoſe who do would moſt likely conſider it only a wretched attempt to compoſe muſic, without ſuſpecting that the notes conveyed two lines of true poetic harmony, from that ſweet poem of Dr. Goldſmith's, "The Deſerted Village;" and, therefore, this method is, in one reſpect, to be preferred to every other yet practiſed, of ſecret writing; *i. e.* that it is leaſt liable to ſuſpicion. An itinerant fidler, or muſician, with his dog's-eared muſic book in his pocket, might get admittance into, or from a town beſieged, unſuſpected. A tune might be pricked down in his book, among many others, and he might be deſired to give a copy of it to any particular perſon where he is going, without ſuſpecting the miſchief, or good office, he is employed to execute, and conſequently unable to betray the ſecret; and though ſuſpicion ſhould ariſe, how will the decipherer know which, among a great number of muſical airs, conceal the ſecret information?

"In this caſe, a good decipherer ſhould be a good muſician alſo, that he may pick out the moſt uncouth and conſtrained compoſition; for that would moſt likely prove to be the harmonic epiſtle. Therefore, to obviate this, and to render the matter leſs liable to ſuſpicion, and much more difficult to be deciphered, (in *Plate* II., *fig.* 4.) an air, compoſed of treble and baſs, according to the rules of true compoſition, is given. In this plate there are a great number of null notes to fill up, and to complete the harmony. The confederate, who is in poſſeſſion of the key and alphabet, will know the null notes by their tails being all turned upwards; and therefore, he paſſes over them, and takes down in order from the baſs and treble cliff thoſe only which are turned downwards, a circumſtance which would greatly perplex the decipherer; firſt, to find out whether all the notes were active; ſecondly, whether the baſs and treble cliff were both employed; and, laſtly, which were the null notes: yet this method is not without ſome inconveniences, and ſuch as would create ſuſpicion or ſurpriſe, in an examiner who underſtands muſic. For, being confined to turn all the nulls one way, and the active notes the other, it muſt ſometimes happen, that both muſt be occaſionally conſtrained, and the tails frequently turned contrary to the uſual practice of writing muſic.

"It is poſſible to render this method of writing ſtill more ſecret, by placing a very thin baſs under the treble, and to put reſts, &c. under ſome of the active notes, and to point out the other by a mixture of liquor (of which there are many) that would not appear till the paper is held to the fire, dipped in water, or fine duſt thrown over it; and, under all theſe impediments, it would be very difficult to come at the ſecret matter: yet it is what a good decipherer would not, I believe, give up as a thing not to be done.

"Were I, however, under a neceſſity to ſend a letter of the utmoſt importance, which was to paſs through the hands, or under the inſpection of cautious examiners, I ſhould think a good piece of harmonic compoſition, without any words annexed to it, the ſafeſt and moſt ſecret vehicle to convey it under. In letters, where it is neceſſary to be particular, as to the day, month, or even the hour, that may be done by a kind of ſhort hand: for it would be very unſafe to write, though in cyphers, *Dear Sir*, at the top of a letter; or *your humble ſervant* at the bottom; or even the month, the year, or the day of the month, as thoſe words would be firſt examined by a decipherer. To avoid any of theſe clues, therefore, where the month and the day are to be given, it may be conveyed according to the Quaker's *bye-way*,—Let the twelve firſt muſic lines be conſidered to ſtand for the twelve months of the year, and then counting from the firſt, to the thirty-firſt, the days of the month. If therefore I would date my letter the 8th of April, a ſmall dot on the fourth line preceding the firſt note, as in *Plate* II. *fig.* 4. would

would imply the *fourth month*, and a little daſh acroſs the eighth line, in the ſame manner, would ſhew it to be dated the *eighth day* of the *fourth month*; and a little *x* from the firſt to the twelfth line, would imply any particular hour in the day; or an *o* the hour of the night.

"It is very certain, that if ſuch a ſentence as the ſpecimen in *Pl.* II. *fig.* 4, contains, can be conveyed by a few lines of muſic, a long letter may eaſily be framed, within the compaſs of an Italian air in ſcore; nay, that *any* Italian piece of muſic of a tolerable length, may, by writing it with the tails properly turned up or down, according to the ſpecimen here given, be made the vehicle of a letter, or a piece of important information; and ſtill more eaſily might a good compoſer convey the words, and the harmony alſo, by the ſame characters.

"I am convinced that a good compoſer of muſic, either by framing the harmony by the alphabet, or the alphabet by the harmony, may not only render every note active, but by harmonic alphabets, might write two letters on different ſubjects, one in the treble cliff, and the other in the baſs; and it is evident, therefore, from the ſpecimen I have given, that the words of a ſong may be conveyed by the harmony; for any judicious ſinger, by dividing properly the words, and repeating them, as is uſual in ſinging ſongs, may ſing thoſe in due time, with the air which conveys them: and though I confeſs I ſee much harm might ariſe from it, yet it may be right to obſerve, by the bye, that an harmonic letter thus written could not eaſily be brought *home* with any degree of certainty (eſpecially where null notes are employed) ſo as to convict the writer in a court of juſtice; yet I cannot think myſelf guilty of an injury to ſociety, in pointing this method out, as it may be productive of much good, as well as of miſchief; for ſecret writing is abſolutely neceſſary on many important occaſions of ſtate."

"It therefore might be right for foreign embaſſadors, or princeſſes, who are ſeparated from their families, by foreign alliances, to be in poſſeſſion of ſome kind of muſical alphabet, by which they may write, or receive letters, which are not ſuſpected to be ſo. The preſent mode, I believe, is, to do all this buſineſs, by what is obviouſly writing in cipher; and that too, by ſome method which has long been in uſe, the key to which, I have *more* than reaſon to believe, moſt of the princes in Europe are in poſſeſſion of. I will hardly believe that the K —— of ——, for inſtance, is a ſtranger to every mode of cryptographical writing by the ſeveral princes and ſtates in Europe. How often do we hear of a courier being murdered, and his diſpatches carried off? and for what other purpoſe but information? and without the key, to decipher letters ſo written, to what purpoſe ſhould they be intercepted by ſuch a deed? I have conſidered every method of ſecret writing which I have heard of, either of ancient or modern practice, and I ſubmit it to the reader's conſideration, whether writing by an harmonic alphabet is not, of all others, the moſt void of ſuſpicion: perhaps I ſhould ſay *was not*; becauſe, having publiſhed it, the ſecret is divulged."

The reader is now in poſſeſſion of all the arguments by which Mr. Thickneſſe endeavours to recommend the practice of muſical writing; and we doubt not that this author has done his beſt, in compoſing the ſpecimens alluded to: but we will venture to predict, that no good judge of muſical compoſition would miſtake his pieces for the productions of a *maſter*.—We have added, in *Plate* II. *fig.* 5. another ſpecimen by a different hand, copied from the Encyclopædia Britannica; which, however, contains only the treble, and is as unſupportably poor and unharmonious as *fig.* 3.—We allow that *fig.* 4, having both the baſs and the treble, looks more like muſic, after the alterations we have made; but if it were perfectly corrected in the mechanical part, it ſtill would be called bad harmony and a puerile compoſition by any real judge of muſic. This latter piece might very poſſibly paſs without ſuſpicion; and then, it ſignifies nothing what faults it contains: only, let it not be held up for imitation, while the tails of ſome notes are turned the wrong way, the treble and baſs ill adjuſted to each other, and the ſeveral component parts of the ſpecimen do not (or, at leaſt, did not, before we amended it) accord truly in time!

If the difficulty of conducting a correſpondence in this way be ſo great, and the labour of compoſing it ſo conſiderable, we ſhould rather give the preference to Lord Bacon's idea of a bi-formed alphabet; which is not more liable to ſuſpicion than the muſical cipher, and is much leſs intricate, as well as better adapted for the uſe of perſons unſkilled in harmonics.

The mere circumſtance of expoſure to *ſuſpicion* may eaſily be ſhunned, by interlining, or writing acroſs any common epiſtle with diluted acids; as for inſtance, with one part of oil of vitriol, mixed in ten parts of water, which will be rendered viſible only when the paper is held to a fire. Authors mention the ſame peculiarity in a ſaturated ſolution of *ſal ammoniac*, and the juice of onions; or, we may write with a ſtrong decoction of galls, which will not be apparent, until the paper has been waſhed over with a ſolution of copperas. (See the article INK.) Another method of preventing ſuſpicion, inſiſted on by Schottus and others, is this:

Take two pieces of paſteboard or ſtiff paper, through which cut long ſquares, at different diſtances, as you will ſee in the following example. One of theſe pieces you keep yourſelf, and the other you give to your correſpondent. When you would ſend him any ſecret intelligence, you lay the paſteboard upon a paper of the ſame ſize; and in the ſpaces cut out, you write only what you would have underſtood by him, and then fill up the intermediate ſpaces with ſomewhat that makes a different ſenſe with thoſe words.

$\boxed{\text{I ſhall be}}$ much obliged to you, as reading $\boxed{\text{alone}}$ engages my attention $\boxed{\text{at}}$ preſent, if you will lend me any one of the $\boxed{\text{eight}}$ volumes of the Spectator. I hope you will excuſe $\boxed{\text{this}}$ freedom; but for a winter's $\boxed{\text{evening,}}$ I $\boxed{\text{don't}}$ know a better entertainment. If I $\boxed{\text{fail}}$ to return it ſoon, never truſt me for the time $\boxed{\text{to come.}}$

A paper of this ſort may be placed four different ways, either by putting the bottom at the top, or by turning it over; and by theſe means the ſuperfluous words may be the more eaſily adapted to the ſenſe of the others.

This is an eligible cipher, ſo far as it is free from ſuſpicion, but it will do only for ſhort meſſages: for if the ſpaces be frequent, it will be very difficult to make the concealed and obvious meanings agree together; and if the ſenſe be not clear, the writing will be liable to ſuſpicion.

It would be an endleſs taſk, which we by no means attempt, to lay before our readers all, or even half, the various methods propoſed for ſecret writing. By far the greater number of them, eſpecially the more ancient ones, are inſecure; and however their reſpective inventors may have held them up to public notice, the art of deciphering has of late been ſo ably cultivated, that very few indeed are entitled to full confidence in a time of extremity. Mr. J. Falconer, who has ſhewn uncommon induſtry and acumen in this way, believed "that the moſt ſure cipher, practicable in a current converſe, may make a diſcovery;" and "if you once underſtand the rules for deciphering in one language, (ſays he) he) you may really and without reservation, in a few hours, understand as much of any other language as is needful to reduce it out of cipher." With like confidence, the learned Conrad, author of "Cryptographia Denudata" thinks this branch of the art is so completely *infallible* "that the explication of any secret writing may be securely undertaken for a large wager." We will endeavour to condense the best rules given for this purpose, not only by both the above authors, but by other persons skilled in deciphering; to which we shall add, occasionally, some practical remarks of our own.

A writer in the Gentleman's Magazine, (June 1761), although he acknowledges himself "not versed in secret alphabets," but who "happened to hit upon one" which gave him an high opinion of his own abilities, was so presumptuous as to affirm "it might be demonstrated that there never hath been invented, and that it is impossible to invent, another cypher which shall not be inferior to his by very many degrees." This overweaning conceit is not at all uncommon in such cases. Persons who have never studiously applied to this subject, are apt to fancy the art of writing by cipher is easily acquired, and that what they "happened to hit upon," perhaps without mature deliberation, is incapable of a disclosure: whereas they who have most seriously weighed all the subtleties of this art, confess that it is a very difficult matter to write by any alphabet, admitting of a current use, without hazarding a discovery of the secret.

The two earliest systematic authors, whose cryptographic labours have descended to posterity, *viz.* Trithemius and J. Baptist Porta, appear to have entertained very high notions of their respective discoveries; but before the end of the sixteenth century, it was found that no method then invented could escape detection, when submitted to the examination of Vieta. (See Dict. Moreri, art. *Vieta*). The modes of writing employed more than forty years afterwards, from A.D. 1642 to 1652, when our countryman Wallis flourished, were also deemed inscrutable by their respective advocates, until this able mathematician proved the contrary. And although some general rules may be laid down for the assistance of decipherers, it is to be observed, "that every new cypher, being contrived in a new way, does not admit any constant method of finding it out; but, (says Dr. Wallis) he that will do any thing in deciphering, must first furnish himself with patience and sagacity; and make the best conjectures he can, till he happen upon something that he may conclude with for truth." (See Davys' Essay on Deciphering, &c. 4to. 1737.) Many writers have handled this science with great learning and ability: but, for an enumeration of them, we refer to Breithaupt's "Ars Decifratoria," 1737; wherein will be seen a regular history of its progress, especially as it relates to deciphering on the continent.

Dr. Wallis properly remarks, that "all persons are not qualified or capable of acquiring the art of deciphering, and that a certain degree of acumen is requisite for this purpose; indeed, those who are equal to the task, are not always willing to give the labour and time necessary to accomplish their design." (Letter to Leibnitz, Jan. 16, 169$\frac{8}{9}$). We are therefore not to wonder that so few persons attain to a moderate degree of excellency, or even endeavour to cultivate this art, in any single age. It is not only requisite that a student should meet with a quantity of writing suitable to the difficulty of the cipher he examines, "without which," says Dr. Wallis, "he may easily fail of success;" but he must obtain all the collateral information possible, relative to the language in which the cipher may probably be written,—the period in which it was composed,—the device mostly used in that period,—the quarter from whence it comes,—the place whither it was destined,—the person for whom it was intended,—and such other external circumstances as will lead to a discovery of the business in agitation; for a decipherer needs all the incidental aids within his reach: he must learn to fortify himself previous to the engagement, "& consilium in arena capere."

We have mentioned the Lacedæmonian scytale as one of the most ancient ways of secret correspondence, (but not invented by Archimedes, as Trithemius and others suppose); and, therefore, it may be proper first to shew the means of frustrating the design of that contrivance. Mr. Falconer, after Scaliger, proposes to join the edges of the paper together by a serpentine revolution, so as to unite both portions of the divided letter, which will give the circumference of the scytale to frame a staff by; or you may add piece to piece, says he, after the first letter is joined, until the solution has been completed. But Mr. Thicknesse wonders that Scaliger did not think of a much more ready method; that is, by cutting the scroll quite through the middle between the half letters, and then, by applying the two broken edges of the letters together, on a table, they will appear perfect so as to expose the reading.

Something like the plan of Polybius, for corresponding by flambeaux, is generally practised during a war at St. Roak, a high situation near Gibraltar, to inform the governor of Cadiz of the number of men of war off Gibraltar, or the number which have sailed out of the bay, &c. which might be disconcerted by exhibiting the same kind of lights at the signal house on Gibraltar-hill, at precisely the same time when the Spaniards shewed theirs. Mr. Thicknesse tells us, the Spaniards, by those lights, expressed letters and figures; nay, that he had even acquired their method in some measure, but dared not disclose it to the English governor, "fearing a court-martial and a cashirement: for I do insist upon it," adds he, "that a governor so ignorant or indolent as not to defeat such a kind of correspondence, would be wicked or foolish enough to punish any officer who presumed to dictate to him," as it would be called. "Yet every information of this kind may be defeated, and false alarms given to the Spaniards at Cadiz, by a governor who would take half the trouble to serve his country which he does to enrich himself and distress those under his command." See p. 33, of "A Treatise on the Art of Decyphering," 1772.

In examining a piece of writing performed by newly invented characters, we should endeavour to ascertain whether the number of them corresponds, or nearly so, with the ordinary number of alphabetical letters. We may sometimes detect a weakness in the writer, of having selected his most simple marks either for the vowels or the first letters in the alphabet, and his complex marks for the consonants or the letters most remote from *a*, *b*, *c*, &c. We must observe which of the characters, whether taken singly or combined, occur the oftenest in the whole specimen; and of these, probably, the most frequent will represent *e*, *a*, *i*, *o*; *e* being much more common than the rest of the vowels, but *u* and *y* are even less frequent than many consonants.

Endeavour next to ascertain the beginning and ending of words, which are sometimes distinguished by spaces, or points, or nulls, interposed; but, however it be done, you must expect these signs to occur after every few letters, and the frequency of their occurrence may serve as some guide.

When you have found out the distinction between words, take particular notice of the order, number, frequency, and combination of the letters in each word; and first examine the characters of which the shortest monosyllables are composed. Remember, 1. That no word can be without a vowel: a word of one letter must therefore be a vowel, or a consonant with an apostrophe. 2. That the vowels are more

more frequently doubled at the beginning of words, than the conſonants; indeed, the latter are only doubled in the beginning of Spaniſh and Welſh words. 3. That the vowels moſtly exceed the conſonants in ſhort words; and when the double conſonants are preceded by a ſingle letter, that letter is a vowel. 4. That the ſingle conſonant which precedes or follows double conſonants, is *l*, *m*, *n*, or *r*. 5. That the letter *q* is always followed by *u*; and when two different characters occur, the latter of which is often joined with other letters, but the former never found alone, nor joined with any than the latter, thoſe characters ſtand for *qu*, which two, except in a few Scotch names, are always followed by a vowel. 6. That although every language has ſomething peculiar in its ſtructure, the foregoing obſervations will apply to all the ſpecimens we have given of the European tongues in the ſeveral parts of this article. See eſpecially the ſeries of examples above, in eight different languages.

In the Engliſh, let it be remarked, that *and* and *the* are more often found than any other words; *h* is frequently preceded by *w*, *c*, *ſ*, and *t*; *y* is ſeldom uſed in the middle of a word; the double letters *ll* and *ſs* appear frequently at the end of words; *ed*, *ty*, *ly*, *ing*, and *tion*, are very common terminations; *em*, *in*, *con*, and *com*, are frequent prepoſitions; *a*, *i*, and *o*, may ſtand alone; *o* is often followed with *u*; *e* is much more frequent in the beginning and end of words than in the middle; and in Engliſh, the *e* is continually employed, as in *yes*, *yet*, *her*, *never*, *me*, *we*, *the*, *he*, *ſhe*, *they*, *ye*, *fee*, *ſee*, *be*, *ever*, *ſpeed*, *need*, *deference*, *excel*, *exceſs*, &c. Though this will not hold good in the Latin, as *e*, and *i*, are equally frequent in the latter, and next to theſe, *a* and *u*; but *o* not ſo common as any of them: and yet, in the Spaniſh and Italian, *o* occurs very frequently. When you meet with a character doubled, in the middle of a word of four letters, it will be neceſſary to conſider what words of four ſyllables are ſo ſpelt. It is probable the vowels *e* or *o*, are theſe; as *meet*, *feel*, *good*, *book*, *look*, &c. In polyſyllables, where a double character appears in the middle of a word, it is for the moſt part a conſonant; and if ſo, the preceding letter is always a vowel.

Obſerve alſo, that *i*, in Engliſh, never terminates a word, nor *a* or *u* except in *flea*, *ſea*, *you*, or *thou*: again, by comparing the frequency of the letters, you will generally find *e* occur the ofteneſt; next, *o*, then *a*, and *i*; but *u*, and *y*, are not ſo often uſed as ſome of the conſonants, eſpecially *s* and *t*. Among the vowels, *e* and *o* are often doubled; the reſt ſcarce ever; and *e* and *y* often terminate words, but *y* is much leſs frequent, and conſequently eaſily diſtinguiſhed.

To find out one conſonant from another, you muſt alſo obſerve the frequency of *d*, *h*, *n*, *r*, *ſ*, *t*; and next to thoſe, *c*, *f*, *g*, *l*, *m*, *w*; in a third rank may be placed *b*, *k*, *p*, and laſtly *q*, *x*, *z*. This remark, however, belongs to Engliſh: for in Latin common conſonants the are *l*, *r*, *ſ*, *t*; next *c*, *f*, *m*, *n*; then, *d*, *g*, *h*, *p*, *q*; and laſtly, *b*, *x*, *z*. But the firſt difficulty is to come at the knowledge of three or four letters, therefore where a word of four letters hath the firſt and fourth the ſame, it is moſt likely to be *that*: to diſcover which look for another of four letters, beginning with the two firſt, and ending with two others, and it will probably prove to be *this*; and more eſpecially if you find another with three letters, beginning with the firſt two, for in that caſe it muſt be *the*. Now having found out in any part of the cipher theſe three words, *that*, *this*, and *the*, place them over the characters which you know to be *t*, *h*, *a*, *i*, *ſ*, *e*, and then conſider what letters are deficient, and what words, from the number of letters which compoſe them, they are moſt likely to be. You will thus find ſuch ready and ſurpriſing intimations from the above ſix deſerters, previouſly apprehended, that you will ſoon be in poſſeſſion of the whole battalion.

Where words of two letters appear of the ſame characters, differently placed, it is moſt likely one is *on*, the other *no*: ſo *of*, and *for*, and *from*, diſcover and convict each other; and *th* are very often uſed in the beginning of Engliſh words, as, *the*, *that*, *this*, *them*, *theſe*, *their*, *thirſt*, *thwart*, &c. &c.

Beſides theſe peculiarities, Mr. Falconer points out the following, as applicable to the Engliſh:

Beginning a word is regularly followed by

A	moſt of the letters.
B	a, e, i, l, o, r, u, y.
C	a, e, h, i, l, o, r, u.
D	a, e, i, o, r, u.
E	moſt of the letters.
F	a, e, i, l, o, r, u, and ſometimes y.
G	a, e, h, i, l, n, o, r, u, y.
H	vowels only.
I	moſt of the letters.
K	a, e, i, n.
L	vowels only.
M	vowels only.
N	vowels only.
O	moſt of the letters.
P	a, e, h, i, l, o, r, ſ, ſometimes t, u, y.
Q	only by u, and QU by a, e, i, o.
R	a, e, ſometimes h, i, o, u, y.
S	a, c, e, h, i, k, l, m, n, o, p, q, t, u, w, y.
T	a, e, h, i, o, r, u, w, y.
U	ſometimes d, and g, l, m, n, p, ſometimes r, ſ, t, x.
V	vowels only.
W	a, e, h, i, o, r, y.
X	ſometimes a, or e.
Y	e, ſometimes i, o.
Z	e, ſometimes o.

It would be too prolix in us to give an equally minute account of the particularities in other languages; but the inquiſitive reader will find them very well ſpecified, in the "Cryptographia Denudata" of D. A. Conrad, 8vo. Lug. Bat. 1739, and in the latter part of Breithaupt's "Ars Decifratoria, ſive Scientia occultas Scripturas ſolvendi et legendi," Helmſt. 12mo. 1737.

To exerciſe the Engliſh ſcholar, we here ſubjoin one example of plain ciphering, in which two figures anſwer to each letter:

39. 38,31,21,35. 35,14,20,18,21,19,20,35,34. 20,38,39,19. 32,35,31,18,35,18. 22,39,20,38. 13,31,14,24. 20,38,39,14, 37,19. 31,19. 20,15. 20,38,35. 13,31,14,31,37,39,14.37. 15,36. 20,38,35. 31,36,36,31,39,18. 18,35,17,21,39,19,39, 20,35. 36,15,18. 24,15,21. 20,15. 11,14,15,22. 18,35,13, 35,13,32,35,18. 20,38,31,20. 15,14, 14,15. 31,33,33,15, 21,14,20. 24,15,21. 36,31,39,12. 20,15. 13,35,35,20. 13, 35. 31,20. 14,39,14,35. 20,15. 13,15,18,18. 15,22,19. 14, 39,37,38,20. 36,15,18. 22,35. 13,21,19,20. 14,15,20. 14, 15,22. 34,35,12,31,24. 20,38,35. 19,21,18,16,18,39,25.35. 15,36. 20,38,35. 33,31,19,20,12,35. 22,38,35,14. 20,38, 39,14,37,19. 31,18,35. 39,21,19,20. 18,39,16,35. 36,15, 18. 35,23,35,33,21,20,39,15,14.

By practiſing the foregoing rules, the ſtudent will find that this method of ſecret writing in plain cipher, may with as much eaſe, if not with as much ſpeed, be deciphered as written.

In all caſes, begin firſt to decipher the ſingle characters and ſhorteſt

ſhorteſt monoſyllables; mark down on a ſeparate paper any correſponding letters and ſigns you diſcover, and count the different characters throughout the piece in order to compare their frequency, &c. It will generally, if not always, happen that the moſt frequent is *e*.

We ſhall now conſider ſome ways of fruſtrating theſe rules, and the methods of procedure in ſuch caſes. The firſt we notice, is that of writing not only without any diſtinction between the words, but alſo by altering their relative poſition: this was the late Earl of Argyle's method, and it was then thought abſolutely undecipherable. See "An Account of the Diſcoveries made in Scotland of Conſpiracies againſt his Majeſty's Government." Mr. Thickneſſe ſays, he has ſeen many ways of explaining this cipher, but, he thinks, the beſt is to mark the concurrence of *proper* words. Take this as a ſpecimen:

I	*know*	*not*	*the*	*grounds*	*our*	*friends*	have
gone	upon	which	hath	occaſioned	them	to	offer
ſo	little	money	as	I	hear	neither	know
I	what	aſſiſtance	they	do	intend	to	give
and	'till	I	know	both	I	will	neither
refuſe	my	ſervice	nor	do	ſo	much	as
object	againſt	any	thing	is	reſolved	'till	I
firſt	hear	what	Mr.	Red	or	any	other
you	ſend	ſhall	ſay	only	in	the	mean
time	I	reſolve	to	let	you	know	as
much	of	the	grounds	I	go	on	as
is	poſſible	at	this	diſtance	and	in	this
way	I	did	truly	in	my	propoſition	mention
the	very	leaſt	ſum	I	thought	could	do
our	buſineſs	effectually	not	half	of	what	I
would	*have*	*thought*	*requiſite*	*in*	*an*	*other*	*juncture*, &c.

When Lord Argyle had written a letter, of which the above is a part of one, he filled up the ſpaces with any words which occurred, and then it appeared thus:

I gone ſo I and refuſe object firſt you time much is way the our would have buſineſs very I poſſible of *I* ſend here againſt my 'till what little upon *know not* which money aſſiſtance I ſervice any what ſhall reſolve *the* at did leaſt effectually thought requiſite not ſum truly this *grounds* to ſay Mr. Thing nor know they as hath grounds occaſioned I do both do is Red only let I diſtance in I half in an of thought my and go you in or reſolved ſo I intend he or them *our friends*, &c. &c. &c.

Now as we obſerved above, mark but the concurrence of proper words, and eſpecially if they be at equal diſtances (and ſo his letter is written) then the number of words between theſe is the column; and thus the buſineſs is done: there may indeed be a proper coincidence by chance; but if you lay hold of ſuch only as aree quidiſtant, they muſt develope the matter where the writer goes down one column and up another. And this is a much readier and more certain method, than that laid down by *Falconer*.

The earl of Argyle was much uſed to write alſo without diſtinguiſhing words; "but," ſays Mr. Falconer, "you may nevertheleſs diſtinguiſh between vowels and conſonants, and each of theſe amongſt themſelves: nay, you may make ſuppoſitions for words; and having found two or three letters, or one word, your difficulty is over: ſo that the rules already laid down, will be ſufficient for deciphering the remainder."

Notwithſtanding Mr. Falconer's extreme confidence, we believe it would be no eaſy thing to diſtinguiſh one word from another, and one letter from another, whether vowels or conſonants, in a ſpecies of writing we ourſelves have invented; of which ſome examples occur at the end of this article, and in *Plate* III.

The inſertion of nulls, or non-ſignificant letters, is another mode of confuſing the cipher; and, to overcome this difficulty, it is requiſite,

1ſt, That you take the number of the different characters in the epiſtle; and if that exceed the number of the alphabet, it is probable mutes are intermixed with the ſignificant letters. We have ſaid probable, becauſe there may be characters inſerted to expreſs relatives and ſyllables, &c.

2. Obſerve the frequency of the ſeveral characters, and by this means you may diſtinguiſh thoſe nulls from ſignificant letters; for it is obvious, that if many inſignificant characters be uſed, they ſhall not be frequent; at leaſt moſt of them ſhall be but rarely inſerted, which will do no great feats: if only a few in number, and conſequently their places the more frequent, they are yet by ſuppoſition diſtinguiſhable from the vowels and conſonants of moſt uſe in writing; eſpecially if you conſider the order and coherence amongſt the ſeveral characters. This admits of no particular rules; nor will the judicious need any.

3. After you have found out the real alphabet, or all the mutes, there is no new difficulty.

There is an invention of ſecrecy much inſiſted on (though none of the ſwifteſt) by the author of the "Secret and Swift Meſſenger," and others; which is, beyond any yet mentioned, for intricacy, wherein each particular line, word, or letter, is written by a new alphabet: but the cited author himſelf acknowledges it too tedious for a current correſpondence, which cannot be entertained this way, but at a vaſt expence of time and trouble, to put it in, or take it out of cipher, even by the key. And ſecret information, in ſeveral exigencies, muſt be ſpeedy, or it will be unprofitable; ſo that in effect it is impracticable for the end it is deſigned.

However, leſt it ſhould obtain too much credit, if ſuppoſed undecipherable, its difficulties are conſidered by Mr. Falconer.

And, firſt, the way of writing by it is this: the confederates determine upon ſome word or ſentence, that ſhall lock and unlock their miſſives; or the key may be ſent in the letter, in ſome word or ſentence privately marked, or by compact agreed on, ſuch as the firſt or laſt line, &c. to ſerve for the key. Suppoſe, ſays Mr. Falconer, it ſhould be "Policy's preheminence," there muſt be ſeveral alphabets framed for each of its letters in the manner following:

1	A	b	c	d	e	f	g	h	i	k	l	m	n	o	p	q	r	s	t	u	w	x	y	z
2	P	q	r	s	t	u	w	x	y	z	a	b	c	d	e	f	g	h	h	k	l	m	n	o
3	O	p	q	r	ſ	t	v	w	x	y	z	a	b	c	d	e	t	g	i	i	k	l	m	n
4	L	m	n	o	p	q	r	ſ	t	u	w	x	y	z	a	b	c	d	e	f	g	h	i	k
5	I	k	l	m	n	o	p	q	r	ſ	t	u	w	x	y	z	a	b	c	d	e	f	g	h
6	C	d	e	f	g	h	i	k	l	m	n	o	p	q	r	ſ	t	u	w	x	y	z	a	b
7	Y	z	a	b	c	d	e	f	g	h	i	k	l	m	n	o	p	q	r	ſ	t	u	w	x
8	S	t	u	w	x	y	z	a	b	c	d	e	f	g	h	i	k	l	m	n	o	p	q	r
9	P	q	r	ſ	t	u	w	x	y	z	a	b	c	d	e	f	g	h	i	k	l	m	n	o
10	R	ſ	t	u	w	x	y	z	a	b	c	d	e	f	g	h	i	k	l	m	n	o	p	q
11	E	f	g	h	i	k	l	m	n	o	p	q	r	ſ	t	u	w	x	y	z	a	b	c	d
12	H	i	k	l	m	n	o	p	q	r	ſ	t	u	w	x	y	z	a	b	c	d	e	f	g
13	E	f	g	h	i	k	l	m	n	o	p	q	r	ſ	t	u	w	x	y	z	a	b	c	d
14	M	n	o	p	q	r	ſ	t	u	w	x	y	z	a	b	c	d	e	f	g	h	i	k	l
15	I	k	l	m	n	o	p	q	r	ſ	t	u	w	x	y	z	a	b	c	d	e	f	g	h
16	N	o	p	q	r	ſ	t	u	w	x	y	z	a	b	c	d	e	f	g	h	i	k	l	m
17	E	f	g	h	i	k	l	m	n	o	p	q	r	ſ	t	u	w	x	y	z	a	b	c	d
18	N	o	p	q	r	ſ	t	u	w	x	y	z	a	b	c	d	e	f	g	h	i	k	l	m
19	C	d	e	f	g	h	i	k	l	m	n	o	p	q	r	ſ	t	u	w	x	y	z	a	b
20	E	f	g	h	i	k	l	m	n	o	p	q	r	ſ	t	u	w	x	y	z	a	b	c	d

If they agree, that the lines only ſhall be written by a new alphabet, the firſt line ſhall be made according to the firſt alphabet A.P. the ſecond line according to the ſecond alphabet, viz. A.O. the third alphabet is A.L. &c. the firſt line being an index ſucceſſively to all the reſt. And when they have gone through the table, they may begin anew, or go backwards again, &c.

If words are only written by one alphabet, then every new word is written by a new alphabet; and ſo of letters. We have hereunto ſubjoined an example for each, viz.

I. *Example in the line.*

Ypb vdgrts id ztte ixt hdaſytgh
idcb wofr rihm obr rihm rxſh:
dfaawi fd, zc cſpi gtww cpfzwe ez
cqn nwuxg bynnmrtg. Qibcn.

I am forced to keep the ſoldiers
upon hard duty and hard diet:
ſupply us, or they will revolt to
the enemy ſpeedily. Haſte.

Solution.

1. When there is only one alphabet uſed for a line, the writing might be diſcovered as in plain cipher, if you make a new operation for each line. But there may be other ways to decipher any ſuch writing: for,

2. If you find out but one letter in a line, (and that may certainly be done by a few ſuppoſitions) it will of itſelf give an alphabet for that whole line, as you may perceive by the counter-table, which follows; for, the confederate's table being framed, ſo as the firſt line may be an index to all the reſt of the lines which are ordered by ſome word or ſentence that is the key, every letter of ſuch a word or ſentence muſt be once ſuppoſed to ſtand for A. Now in the counter-table you ſee all the letters in the alphabet to be once ſuppoſed A: therefore you need only to ſearch for I in the upper line of it, and try in what line Y is oppoſite to it; and thoſe two lines give you an alphabet. Or ſet down the letter found under the letter that expreſſeth its true power, and completing the laſt line, you have the alphabet; *e. g.* if you ſuppoſed Y, in the example given, to expreſs the power of I, firſt write down the twenty-four letters in their uſual order, and under I place Y; then, going on in order, your alphabet is this for the firſt line:

A b c d e f g h i k l m n o p q r s t u w x y z
P q r ſ t u w x y z a b c d e f g h i k l m n o

1	A	b	c	d	e	f	g	h	i	k	l	m	n	o	p	q	r	ſ	t	u	w	x	y	z
2	B	c	d	e	f	g	h	i	k	l	m	n	o	p	q	r	ſ	t	u	w	x	y	z	a
3	C	d	e	f	g	h	i	k	l	m	n	o	p	q	r	ſ	t	u	w	x	y	z	a	b
4	D	e	f	g	h	i	k	l	m	n	o	p	q	r	ſ	t	u	w	x	y	z	a	b	c
5	E	f	g	h	i	k	l	m	n	o	p	q	r	ſ	t	u	w	x	y	z	a	b	c	d
6	F	g	h	i	k	l	m	n	o	p	q	r	ſ	t	u	w	x	y	z	a	b	c	d	e
7	G	h	i	k	l	m	n	o	p	q	r	ſ	t	u	w	x	y	z	a	b	c	d	e	f
8	H	i	k	l	m	n	o	p	q	r	ſ	t	u	w	x	y	z	a	b	c	d	e	f	g
9	I	k	l	m	n	o	p	q	r	ſ	t	u	w	x	y	z	a	b	c	d	e	f	g	h
10	K	l	m	n	o	p	q	r	ſ	t	u	w	x	y	z	a	b	c	d	e	f	g	h	i
11	L	m	n	o	p	q	r	ſ	t	u	w	x	y	z	a	b	c	d	e	f	g	h	i	k
12	M	n	o	p	q	r	ſ	t	u	w	x	y	z	a	b	c	d	e	f	g	h	i	k	l
13	N	o	p	q	r	ſ	t	u	w	x	y	z	a	b	c	d	e	f	g	h	i	k	l	m

22	X	y	z	a	b	c	d	e	f	g	h	i	k	l	m	n	o	p	q	r	ſ	t	u	w
23	Y	z	a	b	c	d	e	f	g	h	i	k	l	m	n	o	p	q	r	ſ	t	u	w	x
24	Z	a	b	c	d	e	f	g	h	i	k	l	m	n	o	p	q	r	ſ	t	u	w	x	y

This *Counter Table* needs not much explanation, being but an exhibition of ſuch alphabets as you may frame by yourſelf upon every new ſuppoſition.

Having found one alphabet for the firſt line, you have likewiſe by this means the firſt letter of the key. *E.g.* In the fifteenth line of the table, Y ſtanding againſt I, and P beginning that line (as you may perceive) P muſt be the firſt letter of the key; and if you peruſe the foregoing collection of what letters can be joined in the beginning of words, you will find *a*, *e*, *h*, *i*, *l*, or *o*, &c. muſt follow P: ſo that at worſt, to get another alphabet for the next line, it will coſt but ſo much pains as to make trial of all thoſe letters by ſuppoſition; as firſt, what letter in the firſt line is againſt *i*, in the fifth line beginning with E, (for A cannot regularly follow P in this particular method, elſe the letters in the ſecond line of the writing ſhould have their uſual ſignification without any tranſpoſition;) and finding that E cannot be the ſecond letter of the key, becauſe the cipher from that ſuppoſition is in as great confuſion as ever, next try what letter is oppoſite to *i* in the line H. Still ſuppoſing a-new, until you find the ſecond line to produce ſenſe. And ſo of all the reſt.

Or you may take the ſame meaſures from the letters or ſyllables found, in the writing itſelf.

Or you may proceed to find the alphabet of the ſecond, third, or any other line, as you did for the firſt, *viz.* ſearching after the power of ſome letter in the ſecond line, by the ordinary rules; and, according to the greateſt probability, in that ſearch, from the frequency of the letter, or other help, to make trial by your counter-table.

II. *Example in the words.*

Y oa qzcnpo cx mggr rfc lgdwbxkl
kedc zriv hzyc hvl mewh puqf:
bdyytg hf, ſw gvrl ylnn wizſpy id
hws pypxi bynnmrtg. Kcvwg.

Solution.

When the alphabet is changed at every word, you may either make ſuppoſitions from words, or from letters that fall in the end or beginning of the ſeveral words in the writing, until you have made ſome progreſs in the letters of the key; and then proceed as before.

You may likewiſe find out by ſuppoſition, the number of letters in the key, &c. which will much facilitate the work. Thus:

1. Having found an alphabet for the firſt, ſecond, or indeed any word near the beginning of the epiſtle, go through all the immediate following words, until you find another that is deciphered by the ſame alphabet.

2. From the laſt found word count the like number, and you have a new word decipherable by the found alphabet: and thus you may go on until you have once gone through the whole writing, marking the whole ſeries with ſome peculiar mark: and then,

3. Begin the epiſtle again at ſome word immediately before or after that which was firſt found, and count forwards as before, until you come to the end of the epiſtle.

4. Afterwards obſerve the ſame method, until you have diſtinguiſhed the whole writing, giving each reſpective ſeries of words ſome particular mark of diſtinction. And in the end, having found out but one letter in ſuch a ſeries of words, it gives an alphabet to decipher all that ſeries by, as was obſerved in lines, &c. *E.g.* Y therefore, the firſt word in the example, expreſſing the power of I, you ſhall find the twentieth word *id* decipherable by its alphabet, *viz.* A. P. and conſequently *hws*, the one-and-twentieth word in the writing, but twentieth after *oa* the ſecond word, to have one alphabet with it; and in the ſame order *pypxi* to have one alphabet with *qzcnpo*; and *bynnmrtg* and *cx* to be denoted by the ſame alphabet, &c.

Now if the writing were long (as it muſt be to contain *Propoſals*, *Emergencies*, and other circumſtances) the uſe of the foregoing obſervations will be evident.

But there is an exception to theſe rules; for you will ſee in the example, that the firſt word Y and the ſeventh word *Lydwbxkl* are written by the ſame alphabet, but not the ſeventh from that, viz. *puqf*, nor the ſeventh from *oa*, viz. *kedc*, &c. and the reaſon is, becauſe the letter P is twice repeated in the words of the key. So that when you find this happen in deciphering, leave ſuch words, and go to the next, until you find the true number of letters that make up the key by the former rule; and then this difficulty becomes a help in the operation, &c.

III. *Example in the letters.*

Y ox oqpvtv yw oqnc yvg xdzorgpl
kgſn mmaq hhwc pbo qcpw ſaib:
xgycpl xx, df eqgw oycp, zigxyy gq
yxs pwgkq hgimhvtl. Mnvyh.

Solution.

To decipher this laſt kind of ſecret writing, you muſt begin with ſuppoſitions; and,

1. Extracting out of it the monoſyllables, &c. you may ſuppoſe all the words in it of three letters ſucceſſively to ſtand for *the*, or *and*, &c. and you may prove your ſeveral ſuppoſitions thus: *viz.* 1. Mark down the powers ſuppoſed. 2. Obſerve in what lines of your counter-table the letters expreſſed in the cipher are oppoſed to them in a perpendicular line. 3. Obſerve the firſt letters of thoſe lines, and you will ſoon find whether they can be joined to make up a part of the key: *e g.* let *yvg* in the firſt line of the example be ſuppoſed *the*; *y* is oppoſite to *t* in line fifth, beginning with E; *h* to *v* line thirteen, beginning N; and *e* to *g*, line third, beginning C. So that having found *enc* in the beginning of theſe ſeveral lines, it is probably ſome part of the key.

2. You may proceed in the ſame manner to other monoſyllables, &c. in any part of the epiſtle; or you may conſider what letters can follow *enc*: and thus *e* being moſt probable, look in that line of your table beginning with E, for *x* the following letter in the cipher, and its oppoſite letter in the upper line, which is S; and afterwards you may go on with probable ſuppoſitions, either from the letters found in the key or in the writing.

Perhaps theſe methods will not ſo readily give you the entire key, yet they are good helps.

You may otherwiſe begin your ſuppoſitions with the firſt letters in the writing; and, for that end, we have heretofore added, in alphabetical order, the letters which can be joined to each other to begin words.

And, from all together, you may in a ſhort time find out the number of letters in the key; and here that is of as much uſe as in the other ways of writing by the key character, ſince thereby you have the ſeveral returns of each alphabet.

When the alphabet is changed for every word or letter, the frequency of the letters will not agree with that in an epiſtle written in plain cipher, where one character always expreſſes the ſame power: for, as to this laſt, you ſhall but rarely find two or three characters of the ſame frequency; but by a continual altering of the alphabet you ſhall have a great

great many. *E.g.* In the last example you have no less than seven different letters twice repeated, viz. *a, b, d, k, f, t, z*, three letters thrice repeated, two letters four times repeated, three letters five times repeated, three letters seven times repeated, and two letters nine times repeated.

Again, in one line of an epistle where the alphabets are continually altered, you shall have more differing characters than in two, where one alphabet is only used in the whole writing. In the example you have the complete number of the alphabet; whereas in the writing,

viz. I am forced to keep the soldiers
upon hard duty and hard diet:
supply us, or they will revolt to
the enemy speedily. Haste.

there are wanting, *b, g, q, x, z.*

We have already observed, that this method of cryptography requires too much time to be put in practice: but besides, it is not only impracticable upon that score, (for by the least mistake in writing, it is so confounded, that the confederate with his key shall never set it in order again) but withal, it is liable to suspicion: so that it has none of those things required in secret writing, except that there is difficulty in deciphering it; and that not insuperable, as is made apparent.

For many of the subsequent, as well as preceding observations, we are indebted to Mr. Falconer; an author we have had frequent occasion to commend, and who particularly excelled in such intricate discussions. As that gentleman's work is very scarce, we shall render the public a service in making some parts of it better known, by these copious extracts.

We next mention the mode of communicating any secret intention with ordinary letters, by the aid of a few figures; which, Schottus says, was the invention of count Gronsfeld, and seems to elude the common rules for deciphering.

1. The confederates dispose the letters of the alphabet in a line or circle, over which they place any number of figures, *e. g.* 436, in this manner.

4 3 6

a b c d e f g h i k l m n o p q r s t u w x y z.

2. They write their secret intentions on a paper apart, and over the tops of the letters they place the number of figures agreed on. Let the words be these:

"The governor of the city is beyond corruption, so that we may conclude there is nothing of briberie will serve the turn."

Which words, according to the example, will stand thus:

436 43643643 64 364 3643 64 364364 3643643643
The governor of the city is beyond corruption,

64 3643 64 364 36436436 43643 64 3643643 64
so that we may conclude there is nothing of

36436436 4364 36436 436 4364.
briberie will serve the turn.

3. Observe what figure stands over the first letter of the writing, (*viz.* T.) which is 4, and counting forward as many letters, write down the fourth, *viz. x*; again see what figure is over the second letter (*viz. h.*) which figure is 3; then counting three letters from *h*, the third is *k*; next write down the sixth letter from *e*, which is also *k*: and so they proceed, always observing the letters in the writing to be secretly communicated, and the figures above it, until they come to the end of the epistle. The example being finished, will stand thus:

xkk kqahtsrt ti wnh eoxa ow dkbqsg etvtasworp yr wndw bh ofb etqeqyfk xkkvg ow ptxkoqi ti dxmdkvlk zlqo vkvxk xkk xxxq.

Solution.

To decipher this kind of secret-writing, you may,

1. Transcribe the cipher out of the epistle, keeping the lines and letters at such a distance from one another, that each letter may admit of a figure distinctly above it.

2. Endeavour to find the number of figures in the key which must be inquired into by several suppositions.

3. The number of figures being supposed, *e. g.* 3, take any three figures, *e. g.* 123, and place them above the tops of the letters in cipher in this order:

123 12312312 31 231 2312 31 231231 2312312312
xkk kqahtsrt ti wnh eoxa ow dkbqsg etvtasworp

31 2312 31 231 23123123 12312 31 2312312 31
yr wndw bh ofb etqeqyfk xkkvg ow ptxkoqi ti

23123123 1231 23123 123 1231.
dxmdkvlk zlqo vkvxk xkk xxxq.

4. Observe where the same character and the same figure happen to fall together, and you will find that thus it always expresseth the same power as in the example; K with 3 placed above it has the power of E through the whole writing; X with 1 upon the top of it signifies H, &c. But,

5. The same letter, when its figure is altered, cannot express the same power: *e. g.* Q with 1, expresses N; but Q with 2 signifies O, and Q with 3, L, &c.

6. One and the same letter will be expressed by different characters: *e. g.* Q with 2, R with 1, and T with 3, express severally O in the writing.

7. Two letters of the same power cannot be joined together in the same character; and, consequently, where you find any character double in a writing of this nature, it expresses different powers.

8. Having made these or the like general remarks, you may proceed to discover particular syllables or words, as in the preceding paragraphs; and having one, you will find with it the true numbers that are contained in the key, at least some of them, which will discover the rest.

It is almost superfluous to add, that in your several operations you must count the letters backwards, since regularly the cipher is written forwards: but because the cipher may be otherwise contrived, you may try both ways, &c.

Of secret writing by points, lines, &c.

The secrecy in an epistle may consist in points, lines, &c. which are distinguishable one from another by their place, not their figure; all of the same situation (whatever the nature of the figure be) expressing the same character. *e. g.* Suppose the paper to be written upon be secretly divided into 24 equal parts, according to the breadth of a plate upon which the letters are described; and then by application of this to the epistle, it is easy to conceive the way of writing it. This is published in the "Secret and Swift Messenger," p. 92. But it contains no great nor new intricacy; for you may extract the points, &c. that fall in the first perpendicular line in any character, and the points that are in the next perpendicular line by a differing character, and those points in the third line by a third character; and so for all the rest, until you come to an end, or rather the side of the epistle, towards the right hand; and then it is resolvable by the common rules.

 Having

Having now removed the moſt material difficulties, ariſing from a change in the powers of the letters; we proceed to

Secret writing, by altering the places of the letters where their powers remain the ſame.

Biſhop Wilkins obſerves, that the difference of characters men uſe in the world, is part of the general curſe upon their once one tongue; and from a parity of reaſon we may infer, that the different methods of writing thoſe characters is ſo too.

The Oriental languages, Hebrew, Chaldaic, Samaritan, Syriac, Arabic, Perſian, Coptic, &c. are written from the right hand to the left. Only the Ethiopic and Armenian proceed from the left to the right hand; as alſo do all the Occidental languages, Greek, Latin, French, Spaniſh, Italian, German, Engliſh, Sclavonic, &c.

At firſt the Greeks wrote from the left to the right hand, and again from the right to the left, forward and backward. Hence *literas exarare* ſignifies *to write*, a metaphor taken from plowing the ground.

Thus the ſenſe of an epiſtle in a known language might be perplexed, if the writing ſhould be contrived after the method of writing ſome foreign tongue. And we have this example from the "Secret and Swift Meſſenger."

T	i	l	w	e	l	d	f	e
h	t	l	ſ	ſ	o	o	t	i
e	ſ	e	u	h	h	u	ſ	l
p	h	n	t	a	o	t	o	h	p
e	t	c	ſ	l	t	t	h	a	p
ſ	o	r	g	l	e	h	t	n	u
t	d	e	n	n	l	e	i	d	f
i	e	a	o	o	b	ſ	w	ſ	y
l	e	ſ	m	t	a	i	e	p	d
e	n	e	a	b	e	e	g	e	e

Here the rows are introduced inſtead of the lines. And if you begin at the firſt letter towards the left hand, and read down that row of letters; then read the next upward, and the following down again; and ſo to the end, you will find theſe words: "The peſtilence doth ſtill increaſe among us; we ſhall not be able to hold out the ſiege without freſh and ſpeedy ſupplie."

This is the ordinary way of writing among the inhabitants of China and Japan. It only needs expoſure, in order to be detected when it occurs.

Another remarkable kind of cryptography conſiſts in altering the places of letters by combination. But it is deſirable, before we proceed, to ſhew how many different ways any given number of letters may be combined, or varied in their relative poſition; for which purpoſe, we ſubjoin a table. (See likewiſe the articles ALTERNATION and CHANGES.) Our calculation is, however, carried no higher than the number of changes in an alphabet conſiſting of 36 letters and figures. Schottus has computed that a thouſand millions of men, in as many years, could not write down the different tranſpoſitions of only 24 letters, if each of them completed 40 pages a day, and every page contained 40 permutations; and Mr. Falconer has ſhewn that this is vaſtly too low a ſuppoſition! So that thoſe tranſpoſitions, inſcribed on a ſcroll, would reach far beyond the planet Mercury!

How much farther then would a chain reach of 36 letters, in their immenſely numerous combinations? For example, in ſuch an alphabet as this, which is adapted for the telegraph at the Admiralty, *viz.*

1	a	b	c	d	e
2	f	g	h	[illegible]	j
3	k	l	m	[illegible]	o
4	[illegible]	q	[illegible]	[illegible]	t
5	u	[illegible]	[illegible]	x	y
:	6	,	8	9	z

Here are 42 places of figures, which may be read thus:

ſextillions	quintillions	quadrillions	trillions	billions	millions	units
371993	326789	901217	467999	448150	835200	000000

i. e. Three hundred and ſeventy-one thouſand nine hundred and ninety-three ſextillions,
Three hundred and twenty-ſix thouſaud ſeven hundred and eighty-nine quintillions,
Nine hundred and one thouſand two hundred and ſeventeen quadrillions,
Four hundred and ſixty-ſeven thouſand nine hundred and ninety-nine trillions,
Four hundred and forty-eight thouſand one hundred and fifty billions,
Eight hundred and thirty-five thouſand two hundred millions.

To write ſecretly by the method here propoſed, a certain number of letters are combined to lock and unlock the epiſtle.

epiſtle. 1. The differences of writing down the poſitions, as, which ſhall be firſt, which ſecond, which third, &c. in order, may be varied to a vaſt number: *e. g.* three letters A, B, C, having ſix regular ways of combination, theſe ſix poſitions are capable of 720 ſeveral orders; for the rows may be combined amongſt themſelves, the ſame way as letters. Therefore,

2. The order of the rows is agreed upon at parting.

3. The number of letters combined, which is the key, may be expreſſed in the epiſtle by ſome mathematical figure, as △ for three letters, □ for four, &c. or by ſome other private mark.

4. They frame a rectangular table of as many columns as there are letters combined.

5. The letters ſo combined are placed in their natural order upon the top of the table.

6. Having determined of how many lines the table ſhall conſiſt, the order of the combinations agreed upon is ſet down in a row, in the firſt column towards the left hand; as you may ſee in the ſubjoined table.

7. The table being thus prepared for writing, they obſerve the order of their combinations, and write according to its direction.

8. When they have placed one letter in every column of all the lines, they begin again, and ſo go on until the writing is finiſhed.

9. Laſtly, they take the letters out of the table according to their partitions, as ſo many barbarous words, upon a paper apart, and ſend it to the confidant.

Example.

Let the key for the number of letters combined be a triangle; and the ſubject of the writing,

"We are big with expectation to know the ſucceſs you have had, whether the arms you have undertaken for will be ready upon occaſion. Let your next be written by the ſquare key."

Form of the Table for Writing.

Order of Poſitions.	A	B	C
1 CBA	*a t ſ a ſ k d e t*	*e c e h m a a l i y*	*w e h e r t e n r e*
2 CAB	*e t c w o n u y y*	*b i c h u ſ p o t*	*r a u d y e y t b*
3 ACB	*i o e e h o o u h*	*w t ſ h v w o n s*	*g n ſ t a r n r e*
4 BCA	*h n u t n l a t a*	*i o y e e i c e q*	*t k o r u l c x u*
5 BAC	*x w a e e e i e e*	*e o h h d b ſ b r*	*p t v a r r o w k*

A further Explanation of this Table.

CBA, being the firſt poſition, *w*, the firſt letter in the writing is placed under C in the laſt column; and *e*, being the ſecond letter, is put under B in the next column; and *a*, the third letter, under A.

CAB, being the ſecond poſition, the fourth letter in the writing, *r*, falls in the ſecond line under C; the fifth letter, *e*, under A; and the ſixth, *b*, under B in its column, all in the ſame line.

ACB, being the third poſition, the ſeventh letter in the epiſtle, *i*, is put under A in the third line; the eighth letter, *g*, under C; and the ninth letter, *w*, in the column B.

And ſo they go through the writing, always beginning again, when they are at the end of the table, ſo long as there is any thing to write.

The writing taken out of the table will ſtand thus:

△ *Atſaskdet. ecehmaaliy. wehertenre.*

etcwonuyy. bichuſpot. raudyeytb. ioeehoouh.

wtshvwons. gnstarnre. hnutnlata. ioyeeiceq.

tkorulcxu. xwaeeeiee. eohhdbsbr. ptvarrowk.

The terminal letters may be ſo marked to prevent confuſion.

We have inſiſted the more upon this method, becauſe the manner of combining, and the way of writing by ſuch combinations being once perfectly underſtood, the rules for deciphering may be the more ſuccinct, and the more eaſily comprehended.

Solution.

1. If the figure of the key be prefixed to the epiſtle, expreſſing the number of letters combined, take as many letters out of the firſt places of ſeeming words in the epiſtle as ſhall be equal to that number ſo expreſſed, and you may ſoon find out their true order without the trouble of a new combination; though the trouble of combining is not ſo very great, as the diſcovery of a treaſonable deſign may be of importance to the public.

Thus in the example given, you have △ (which muſt be ſuppoſed to ſhew that three letters are combined); extract the three firſt letters from the three firſt ſeeming words of the epiſtle, viz. *a*, *e*, *w*, here at firſt view you may perceive the order. Then taking out the next three letters, *e*, *b*, *r*, you have *a* for the firſt letter of the word from the firſt line, and *e* for the laſt letter; and then you are only to conſider whether *b* or *r* is the middle letter, which is eaſily determined; ſo *b* (being left out there), muſt be the firſt letter of the next word: thus you may proceed, for it is needleſs to enlarge in a caſe ſo plain.

2. If there be no key given, take the number of partitions of ſeeming words in the epiſtle, and find our their ſeveral diviſors; which may be performed by the following rules.

How to find out the equal Diviſors of any Number.

1. Divide the number given by ſome prime number, *i. e.* ſuch a number that cannot be divided but by itſelf, or unity, and the quotient by ſome or other prime number, and the laſt quotient again by a prime number, and ſo go on until the laſt quotient of all be one; and thus you ſhall find a certain number of prime diviſors.

2. Make a rectangular table that ſhall conſiſt of as many columns as you have prime diviſors, which you muſt place one after another at the tops of the columns; and by help of them you will find all the reſt of the diviſors, *viz.*

By multiplying the firſt prime diviſor, towards the left hand of the table, by the ſecond, and writing the product under the ſecond. Next, by the third prime diviſor, multiplying all the figures in the table towards the left hand, ſetting the ſeveral products in the third column; and ſo forth, throughout all the prime diviſors, but with this caution, that one product be not written twice: and in the end, the ſeveral numbers in your table will be all the aliquot parts, or juſt diviſors of the given number.

Example, to find out all the Diviſors in 450.

450	225	75	25	5	1
2	3	3	5	5	

The

The firſt line contains the firſt dividend, and the reſpective quotients; the loweſt line is the ſeveral prime diviſors.

Now 450, the number given, being divided by 2, a prime diviſor, the quotient is 225; which being divided by 3, you have 75 for a new quotient; and that again divided by 3, you have 25 for another quotient. This laſt divided by 5, gives 5, which being a prime number, you have 1, or unity in the laſt quotient of all; ſo that your prime diviſors are, 2, 3, 3, 55, all which ſet down in the tops of the columns, and multiplying them according to the rule given, the operation will ſtand thus:

2	3	3	5	5
	6	9	10	25
		18	15	50
			30	75
			45	150
			90	225
				450

All the diviſors of 450, are 2, 3, 5, 6, 9, 10, 15, 18, 25, 30, 45, 50, 75, 90, 150, 225; and one of them (ſuppoſing the epiſtle to have conſiſted of 450 ſeeming words) ſhould have been the number of letters combined for the key: for the number of ſeeming words in ſuch an epiſtle is equal to the rectangle made of the figure of the key, or number of lines; and conſequently the figure of the key, or number of letters combined, is ſome aliquot part, or equal diviſor of the number of ſeeming words.

But to ſave all trouble in ſearch of the key, you may take a certain number of letters out of the firſt places of the ſeeming words, and write them down in a line; next, take juſt as many letters out of the ſecond places of the ſame partitions, and then the letters out of the third, fourth, fifth places, &c. placing them directly one under another in order; or rather, for diſpatch, take out the ſeeming words, and write them down in rows, beginning at the firſt, and then proceed to the ſecond, third, fourth, fifth, &c. until you have gone through them; and if the number be too great, take as many as you think fit at a time, placing all the dots you find above the heads of the letters at their ſides. *e.g.*

	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
1.	A	e.	w	e.	b	r	i	w	g.	h.	i	t	x	e	p
2.	t	c	e	t	i	a	o	t	n	n.	o.	k	w.	o	t
3.	ſ	e.	h	c	c	u	e	s.	s	u.	y	o	a	h	v
4.	a	h	e.	w	h	d.	e	h	t	t	e	r.	e.	h	a
5.	s.	m	r	o	u.	y	h	v	a	n	e.	u	e	d	r
6.	k	a	t	n.	f	e	o	w	r.	l.	i	l	e.	h	r
7.	d	a	e	u	p	y.	o	o	n.	a	c	c	i	s	o
8.	e	l	n.	y	o	t.	u	n	r.	t.	e	x	e.	b	w
9.	t.	i	r	y.	t	b	h	s	e.	a	q	u	e.	r	k
10.	—	y.	e	—	—	—	—	—	—	—	—	—	—	—	—

We have marked the lines and rows with figures for their more eaſy diſtinction.

Having brought the writing into this order,

1. Search in the ſeveral lines for ſome of the particles of that language you may ſuppoſe the epiſtle to have been written in; if in Engliſh, make ſuppoſitions, *e.g.* for ſuch little words as *the*, *that*, *for*, *of*, *to*, *and*, &c. and the like, without ſome of which no man can well expreſs buſineſs of any moment.

2. Having ſearched in any of the lines for ſome one of thoſe mentioned, or the like particles, you may prove the truth of your ſuppoſition, by taking out the oppoſite letters of all the other lines; and if they do not make up words, or ſyllables, or produce ſuch letters as can probably follow one another in that order, your firſt ſuppoſition is falſe, and you muſt gueſs again.

3. Having by freſh ſuppoſitions found ſome uſual word, and the letters of the other lines in the ſame order agreeing, the words or ſyllables ariſing from them will direct you to ſome new row that goes before or after in their true order; and thus you may proceed till you have found out the whole writing, which by this time will be no great difficulty.

Example.

In the ſixth line you have *f* once, *o* once, and *r* twice; ſo that probably amongſt theſe letters you may find the word *for*; and upon trial, the ſuppoſition is proved by the other lines: *e.g.* line 6 by lines 1, 2, 3, 4, 5, 7, 8, 9.

Rows	5	7	9
6.	*f*	*o*	*r.*
1.	b	i	g.
2.	i	o	n.
3.	c	e	s
4.	h	e	t
5.	u.	h	a
7.	p	o	n.
8.	o	u	r.
9.	t	h	e.

Here in the fifth line you find *u* a terminating letter; which muſt then have before it the vowel *o*, as in *you*, or *e*, as in *lieu*. And in this line you have *o*, once, and *e* twice; ſo that in three ſuppoſitions at moſt, you ſhall have the preceding row in its natural order; thus ſuppoſing it, *o*, in the fourth row that joins the vowel *u*, the writing will ſtand thus:

	4.	5.	7.	9.
1	e.	b	i	g.
2	t	i	o	n.
3	c	c	e	s
4	w	h	e	t
5	o	u.	h	a
6	n.	f	o	r
7	u	p	o	n.
8	y	o	u	r.
9	y	t	h	e.

Now, having *ou*, it is moſt probable that *y* is wanting to join with it; which, ſtanding in the ſixth row of the line, write down that row in order thus:

	6.	4.	5.	7.	9.
1	r	e.	b	i	g
2	a	t	i	o	n.
3	u	c	c	e	s
4	d.	w	h	e	t
5	y	o	u.	h	a
6	e	n.	f	o	r
7	y.	u	p	o	n
8	t.	y	o	u	r
9	b	y.	t	h	e.

And ſo you may go on until you get through the whole writing; which will in the end ſtand thus:

W	e.	a	r	e.	b	i	g.	w	i	t	h.	e	x	p
e	c	t	a	t	i	o	n.	t	o.	k	n	o	w.	t
h	e.	ſ	u	c	c	e	ſ	s.	y	o	u.	h	a	v
e.	h	a	d.	W	h	e	t	h	e	r.	t	h	e.	A
r	m	s.	y	o	u.	h	a	v	e.	u	n	d	e	r
t	a	k	e	n.	f	o	r.	w	i	l	l.	b	e.	r
e	a	d	y.	u	p	o	n.	o	c	c	a	s	i	o
n.	L	e	t.	y	o	u	r.	n	e	x	t.	b	e.	W
r	i	t.	b	y.	t	h	e.	s	q	u	a	r	e.	K
e	y.													

There

There are ſometimes other helps obvious, to diſcover the ſenſe of an epiſtle obſcured by this invention; *e. g.* you ſee only two letters falling in the laſt line of the example; whereby I not only conclude that the epiſtle ends with them, but may alſo infer from the ſuppoſition of a regular procedure in writing it, that the letter began at ſome of the ſeeming words that compoſed thoſe two rows, *viz. ecehmaaliy*, or *wehertenre*. The reaſon is evident, &c.

This method of ſecret-writing is, at firſt ſight, diſtinguiſhable from any other, only by obſerving the equality in the diviſion of its letters.

There are great varieties of inventions of this kind, more eaſy to the confederates; whereby they only write their ſecret intentions in a parallelogram, or other mathematical figure, and confound the ſenſe, by the method of extracting it. (See the "Account of Diſcoveries made in Scotland," p. 18, &c.)

Of ſecret-writing by means of a parallelogram, where the letters are extracted out of that figure diagonally.

To perform this, a man needs only form a parallelogram or table, and without any combination or other obſcurity in the writing, inſert his ſecret intentions therein; *e. g.* let the ſenſe of the epiſtle be,

"I ſuppoſe that things are ſo forward by your diligence, that we may adventure at all, once next week: meet me towards ten to-morrow's night at the old place."

It is firſt inſerted in the table thus:

I.	ſ	u	p	p	o	ſ	e.	t	h	a	t.	t	h	i	n
g	s.	a	r	e.	ſ	o.	f	o	r	w	a	r	d.	b	y.
y	o	u	r.	d	i	l	i	g	e	n	c	e.	t	h	a
t.	w	e.	m	a	y.	a	d	v	e	n	t	u	r	e.	a
t.	a	l	l.	o	n	c	e.	n	e	x	t.	w	e	e	k.
m	e	e	t.	m	e.	t	o	w	a	r	d	s.	t	e	n.
t	o-	m	o	r	r	o	w	s.	n	i	g	h	t.	a	t.
t	h	e.	o	l	d.	p	l	a	c	e.	*b*	*x*	*y*	*ſ*	*q*.

Here the laſt five letters *b, x, y, ſ, q*, are of no uſe but to fill up the void places in the table.

The firſt method of obſcuring the meaning of ſuch an epiſtle is, by copying it out of the table diagonally, upon a paper apart; *i. e.* by ſuppoſed lines extending from the ſecond letter in the firſt row towards the left hand, to the ſecond of thoſe in the uppermoſt line, and from the third letter in that row to the third in the upper line; next from the letters of the laſt line to thoſe in the upper line that remain, and then to the laſt row towards the right hand, &c. *Diagonal* is a mathematical term, from διὰ, and γωνία, an *angle* or *corner*.

Example.

They firſt write down *I*, beginning at the upper corner of the parallelogram; next they take the other two letters which lie in order to it, *viz. g, s*; then they extract the next three in order, *viz. y, s, u.* And ſo they go on until they come to the laſt corner, *viz. q.* The whole writing being extracted in this manner, will ſtand thus:

I. g s y s. u t. o a p t. w u r p m a e. r. e. o t e l m d ſ s t o- e l. a i o. e. h m t. o y. l f t e. o m n a i o h o r e. c d g r a l r t e. v e w t. d. o o n e n a t p w w e n c r h l s. a x t e. d. i a n r t. u t b n c i d w r h y. e. g s. e e. a *b* h t e a *x* t. e k. *y* a n *ſ* t. *q*.

For the ſolution of this and ſuch like manner of ſecret writing, the only difficulty is to find out the number of the lines and the number of rows. And here you may obſerve that the number of letters in the epiſtle is equal to the rectangle made of the number of lines and rows; ſo that if you take the diviſors or aliquot parts of the number of letters, you may find out the number of lines and rows by a few ſuppoſitions, and conſequently, the involved meaning.

Nay, you may ſoon diſcover any writing of this nature, by reducing the letters of the epiſtle into diagonal lines, as if you had found out its true figure; *e. g.*

Firſt, you may mark down *I*, the firſt letter in the writing, by itſelf, as in the margin. Next write the two following letters, *g, s*, by it thus; then to theſe join the three following letters *y, s, u,* thus; afterwards the following four letters *t, o, a, p*, thus; and ſo of the following five letters, &c. You will perceive when words or ſyllables appear; and withal if you obſerve the coheſion of words or letters, between the end of the firſt line, and the beginning of the ſecond, you will find out where theſe two lines join in the ſenſe, and, conſequently, where the firſt line ends: thus you ſhall have the number of rows, by which, if you divide the whole letters, the quotient gives you the number of lines, &c.

I

I. s.

I. s u p
g s. a
y o
t.

This way of deciphering may ſeem to be eluded two ways:

1. By beginning (when they copy the epiſtle out of the table) at ſome of the other angles.

2. By inſerting nulls before the epiſtle.

As to the firſt, if they begin at the lower angle towards the left hand, the words will diſcover themſelves as before. Only the order of the lines will be reverſed in the operation, *viz.* The firſt line is laſt in the true order, &c. 2. If they begin at the upper angle of the parallelogram towards the right hand, the lines will be in their true order, but the writing muſt be read backwards. 3. If, at the lower angle towards the right hand, the order of lines will be reverſed, and the writing muſt alſo be read backwards. This holds true by the ordinary operation; but you may frame your figure for diſcovery, according to theſe three ſuppoſitions, *viz.* beginning it at any corner, &c. Yet, we think, the ordinary operation will give the ſpeedieſt reſolution.

Note. From beginning at the lower corner towards the right hand, you are not to expect words or ſyllables in the beginning of the firſt line by your operation, ſeeing it is laſt in the true order; and mutes, perhaps, may be inſerted to fill up the void places in the figure, ſo that you muſt obſerve the other lines.

As to the ſecond method, by inſerting nulls before the epiſtle, they may, in proceſs of time, be diſcovered thus:

When, upon trial, you find the writing in the epiſtle will make nothing of ſenſe, lay aſide the firſt letter, and make a new ſuppoſition with thoſe remaining; if nothing yet appear, lay aſide two letters, and proceed as before; then leave out three, four, &c. until you perceive words.

We next ſhall analyſe that kind of writing in which *more letters are uſed than are requiſite.* The firſt remarkable, and very ordinary, contrivance in ſecret writing, by more letters than uſually go to the framing of words, is that inſiſted on by Schottus, (in his "Scholia Steganographia,") *viz.*

1. The confidants at parting frame an alphabet of figures to write by; *e. g.*

A	b	c	d	e	f	g	h	i	k	l	m	n	o	p	q	r	ſ	t	v	w
4	22	10	9	1	11	13	18	3	19	12	8	20	2	21	23	7	6	5	15	14

x	y	z.
16	17	24.

2. Having written down their ſecret intentions on a paper apart, they contrive an epiſtle of ſome ordinary buſineſs in any language.

3. They ſearch for the numbers of the alphabet that expreſs

expreſs the letters of the ſecret writing; and counting the letters in the common miſſive from the beginning, they ſubjoin ſome private mark under every character where the reſpective numbers end; *e. g.* Let the ſecret intimation be this:

3	6	18	4	12	12	6	11	16	2	15	5	18	3	6	20	3	13	18	5	4	5
I	*ſ*	*h*	*a*	*l*	*l*	*ſ*	*ee*	*y*	*o*	*u*	*t*	*h*	*i*	*s*	*n*	*i*	*g*	*h*	*t*	*a*	*t*
16	2	15	7	12	2	9	13	3	20	13	6										
y	*o*	*u*	*r*	*L*	*o*	*d*	*g*	*i*	*n*	*g*	*s.*										

And the epiſtle may run thus:

"Having underſtood that I could not be ſafe any longer where you are, I have choſen rather a voluntary baniſhment to wander with my liberty abroad, than to lie under the daily hazard of loſing it at home: 'Tis in my opinion the leaſt of the two evils. 'Tis true, I am innocent; but innocence is not always a buckler; ſo that I hope you will not condemn, even though you cannot approve my choice, at leaſt till you have the particulars of my caſe; which expect *per* next."

You ſee the figure for the firſt letter, to be put in cipher, is 3; therefore a ſecret mark or point muſt be placed directly under, or above, the third letter of the epiſtle, *viz. v;* and number 6, expreſſing the ſecond letter in ſecret writing, a dot muſt ſtand under the 6th letter from *v*, *viz.* under *n;* and 18 letters from *n*, will ſtand another dot, &c.

Example.

Having underſtood that I could not be ſafe any longer

where you are, I have choſen rather a voluntary baniſhment,

to wander with my liberty abroad, than to lie under the

daily hazard of loſing it at home: 'Tis in my opinion the

leaſt of the two evils. 'Tis true I am innocent; but inno-

cence is not always a buckler; ſo that I hope you will not

condemn, even though you cannot approve my choice, at

leaſt, till you have the particulars of my caſe; which expect

per next.

Theſe points may be written with ſuch ink that they ſhall not be viſible, till held by the fire, or dipt in water, &c.

Solution.

For deciphering this, you have no more to do, but take the number of letters, from the beginning of the epiſtle to the firſt point, from that to the ſecond, and ſo from point to point until you come to the laſt; writing down the ſeveral numbers, diſtinctly one after another, and then you have it in a plain cipher reſolvable by the former rules.

Nich. Machiavel tells us, that in his own time a certain perſon deſigning to ſignify ſome ſecret intention to his friends, interlined private marks in letters of excommunication that were to be publickly affixed, by which the ſecret was afterwards communicated to the confederates; and this has in all probability been performed by the former or ſuch-like method of ſecret information.

We have already conſidered the obſcurity ariſing from the inſertion of nulls at random, as to ſeveral of the ways of ſecret writing mentioned: but here we ſhall inquire into them as inſerted by compact, either to prevent or divert ſuſpicion; and indeed the great deſign of perſons who uſe them, is generally one of theſe two.

When they would quite remove ſuſpicion, the epiſtle is ſo contrived, as to outward appearance, that it may appear to have nothing in it but ſome trivial buſineſs, as news, &c. or a private concern, as borrowing of money, paying of bills, &c.

But if the perſon to whom the epiſtle is written might render the paper ſuſpected, they endeavour to divert that ſuſpicion, by inſerting a falſe deſign to cloak a true one.

The nature of this ſecrecy will more fully appear in the ſubſequent examples:

Suppoſe two or more confederates had agreed to confine their ſecret intentions to one ſide of the paper in the writing, according to ſome private compact. Thus, upon diſcovery of a plot, if a ſpeedy flight were deſigned, and to be communicated by this contrivance, it might be written at firſt in the following manner:

This meaſure is not
ſecret; there is now no
ſafety but by flight
Do not fail to meet me
half an hour hence
Let the next meeting be
juſt without the gate
(if my ſenſes are ſound)
we may conclude to have
clear infallible evidence
the ſnare is prepared,
effectually to entrap
you and

Your, &c.

POST-SCRIPT.

Pray
expoſe not yourſelf to
imminent danger.

Now to obſcure the ſenſe and prevent ſuſpicion, the unfiniſhed parts of the lines may be ſupplied with ſomething foreign to the deſign; and afterwards the epiſtle is to be pointed according to the ſeeming ſenſe; *e. g.*

This meaſure is not in danger; to all it is as yet
ſecret; there is now no thing in view to threaten our
ſafety, but by flight we ſhould ruin all our deſigns.
Do not fail to meet me by ſix in the uſual manner:
half an hour hence, I intend to be at the council.
Let the next meeting be where they will, I'll have notice:
juſt without the gate was the governor this morning
(if my ſenſes are ſound) ſecure as we could wiſh him;
we may conclude to have hit right on the means, and more
clear infallible evidence is not on this ſide conjuration:
the ſnare is prepared, they are miſled, and ſee not 'tis
effectually to entrap them, and on their ruin to raiſe
you and

Your, &c.

POST-SCRIPT.

Pray throw off thoſe vain fears:
expoſe not yourſelf to ſcorn, when there is not any
imminent danger.

Here to divert ſuſpicion of what is deſigned for the confederates, the ſecret intelligence is divided from the reſt of the epiſtle, by a ſuppoſed perpendicular line; but however it be divided, the ſenſe cannot well eſcape a diſcerning eye: and to propoſe a ſolution would be ſuperfluous.

We

We have already detailed Lord Bacon's mode of secret writing, and need not much enlarge on the means of deciphering it; for if you once find out whether two or three alphabets be used, (and the different kinds of letters in the epistle will inform you of that,) you may suppose one alphabet *a*, a second to stand for *b*, and if there be a third, let it be supposed *c*. Afterwards extract the writing out of the epistle, as if these letters *a*, *b*, or *c*, only, were inserted; and then it falls under the former considerations.

It is nothing to the purpose, whether your supposition and the writer's be the same, or not; for if you suppose always an *a* for his *b*, the operation will be alike easy.

This way of secret correspondence will therefore signify very little, unless to spend the time and paper of the writer: for if you put a mark of distinction between every two, three, or five, of the characters (as they make up a significant letter) they are liable to discovery the same way as an ordinary cipher.

And it is easily discernible when two, three, or five characters express one letter, either from the number of characters in a word, or in the whole writing;—

1. From the number in a word: for when two letters go to the composition of the alphabet, they must have five places; and the words will consist of 5, 10, 15, 20, or 25 letters, *&c.* If three letters are in three places, you will find 3, 6, 9, 15, or 18 characters, *&c.* in each word: if five letters in two places, the words shall have 2, 4, 6, 8, 10, or 12 characters, *&c.* a piece.

2. From the number of the letters in the whole; as if two be only used, in one rank, you shall have five differing characters in the whole at least: e. g. *a*, *b*, *c*, *d*, *e*. If three in a rank, then you may have 3 characters: e. g. *a*, *b*, *c*; and if 5 in a rank, you will possibly have but 2 characters in the writing, *&c.*

By these remarks it will be seen, that Lord Bacon's plan of writing *omnia per omnia*, as he calls this we allude to, is not deemed undecipherable, although it possesses the merit of ingenuity: and indeed all alphabets composed after that manner, in which each letter is represented by one uniform sign (whether composed of few or many characters does not matter) will be liable to exposure; because if you once find out the substitute of any single letter, you discover it in all other instances where that same letter is represented. Thus, suppose *aabaa* to signify *E*, this letter will be always found by detecting its substitute *aabaa*, and of course the recurrence of every other letter may be easily known; so that you are not embarrassed by this cipher with any extraordinary difficulty, as some inexperienced men have imagined.

And here we shall leave this kind of cryptography by *more letters*, *&c.*

The reader who duly attends to the foregoing directions, will be able to extend his knowledge to a variety of other methods, in which *fewer letters* or characters are used than are commonly required in forming words: but of this kind, the most difficult of all, which indeed we fear it is impossible to decipher, is the mode that consists in representing whole words, or even sentences, by single notes and figures. For by this method, we confess, there seems to be no ground whereon a decipherer can set his foot, no principle by which he may be guided in his operations; but all must be conjecture, and discouraging uncertainty! On many accounts, however, the alphabetical modes of writing are preferable for ordinary use; as the labour of putting an epistle into cipher and taking it out, by any other process, is insufferably tedious and operose.

One of the ingenious conceptions of a lady who intended to puzzle Mr. Thicknesse with a new cipher, was this. She composed an epistle in English by means of Etruscan characters, and rendered the whole, according to the French orthography, after the following manner:

"Sur, as yeux air il, doux comme & change the climat: here, yeux mai have game, fiche, duc, fat mutin, foule, porc, aile, port, fruit, & admirable menchette and butter; an mi sistre (a joli nymphe) tu chat tu yeux, & sing yeux an ode, tu the lute, or violin: yeux canne have a stéble for ure hors, & a place for ure chaise. Mi son met a physician néér the river, tisse fêtal signe! thé sai, the pour Docteur dos grive about the affaire, oing tu the rude Squire:—but pardon mi long lettre, pré doux comme tu us about mai, if yeux canne: mi service tu ure niece: hoüe dos Rasse doux?

Adieu mi friend

"P. S. [illegible]

"Pré doux comme; for ure pour Nenni seize but feu beaux."

This feminine production would create no difficulty to a decipherer who understands French, but might perhaps help a little to perplex any other person, on his first entering upon the task. We add a device of our own, with which some other lady may possibly amuse herself. The means of deciphering it will be obvious, we suppose, from what has been said in the preceding pages:

Take a sufficient number of ornamental beads of five colours, (though fewer will do); and string them upon a thread in pairs, according to the plan of combining two signs for one letter. Suppose them to be red, green, yellow, black, and white; an alphabet may then be formed many thousand ways, of which the following is one: Let A be red and green; B, red and yellow; C, red and black; D, red and white; E, green and red; F, green and yellow; G, green and black; H, green and white; and so on, with the other letters. Now, when a message has been composed after this manner, upon a long thread, it may serve for an ornament to some person's neck; or it might pass in a basket of pedlar's toys, without the slightest suspicion of its insidious contents. If only three colours were used, three beads must unite in representing each letter.

Among the incredible pretensions of men who have studied the art of cryptography in former times, we find this one of Trithemius, who certainly mistook his own talents in several particulars:—"Possum hominem idiotam, scientem tantum linguam maternam, qui nunquam novit verbum Latini sermonis, in duabus horis docere scribere, legere, et intelligere Latinum satis ornatè et disertè, quantumcunque voluerit; ita ut quicunque viderint ejus literas, laudent verba, intelligant Latinè composita."

The idea here held out, of teaching an ignorant person to write, read, and *understand* elegant Latin, in two hours, although he never before knew one word of it, is most absurd, and repugnant to all our experience of human ability! None but the Almighty himself could thus instantaneously confer the power of *understanding* a foreign language: although, without doubt, a man who can write, may be taught to copy any Latin words in less than two hours. And Trithemius seems to have attempted nothing more.

To explain this, suppose a great multitude of common alphabets written in order; and to each of the letters in those alphabets synonymous Latin words are annexed, as denoting the respective letters. If all the words expressing A, in the different alphabets, make up an oration, and all the words in each rank be of like signification; and if A, in writing by this method, begins the first alphabet: let one word be taken from thence, another from the second, and another from the third alphabet, as they are required, until the intention of

 the

the writer ſhall be fulfilled : it is eaſy to perceive how a man, unacquainted with Latin, ſhall thus write it " ſatis ornatè et diſertè ;" but he would nevertheleſs remain totally ignorant of the meaning of thoſe Latin words, any otherwiſe than as they expreſſed the various letters for which they were ſubſtituted, and whereby he has compoſed ſome ſecret meſſage conceived in his mother-tongue. We here remark,

1ſt. That there muſt be a new alphabet conſtructed for every letter in the ſecret writing.

2. Theſe alphabets require a more than ordinary degree of ingenuity in their contrivance.

3. When the alphabets are exactly framed, the leaſt miſtake in the writer turns the ſecret intimation into a chaos.

4. But ſuppoſe there were nothing amiſs in the whole deſign, (which is enough in all conſcience freely to grant,) yet there is much more time required in writing and reading, by this artifice, than a man in buſineſs can diſpenſe with : for, (as we have before ſaid) according to Trithemius the key muſt contain as many alphabets as the ſecret epiſtle has letters in it. Now in Argyle's long letter inſerted in the diſcoveries made in Scotland, there are upwards of a thouſand words ; and if he had taken Trithemius's way of concealing it, there would have been five or ſix thouſand alphabets uſed in the key : we leave it to arithmetic to reſolve, how much time a particular ſearch into each of thoſe alphabets will amount to ; and to ſtoiciſm, (for none but men of that ſect will try) how much patience.

Athanaſius Kircher, in his " Steganography," endeavours to improve Trithemius's method. The alterations we obſerve are theſe,

1. Kircher contrives his key in the form of any ordinary epiſtle ; whereas Trithemius conceives his in forms of prayer, which are more liable to ſuſpicion, eſpecially in an age, when the greateſt villainies are committed under a mere form of godlineſs.

2. Kircher has alphabets of ſeveral languages, whereby a man may chooſe what ſpeech he pleaſes for his exterior letter, though he underſtand not the genuine meaning of one word. But this was propoſed by Trithemius.

3. Kircher's key conſiſts not of many words ; ſo that, if the ſecret or interior epiſtle be not conceived in a few, it gives ground of ſuſpicion and of reſolution too,—

For the words that expreſs every particular alphabet, as before, being of like ſignification, (that the outward writing may have a ſeeming ſenſe,) at every few lines you ſhall have the ſame ſenſe, though not in the ſame words; which gives ground to ſuſpect it, and if the writing be long to attempt a ſolution.

Again, ſuppoſe that ſeveral letters, written by the ſame key, were ſeized, (which is no great improbability) the ſenſe of all will be to the ſame purpoſe ; and that gives cauſe enough of jealouſy, and facilitates the diſcovery.

The compiler has now laid before his readers a conciſe hiſtory of the origin and progreſs of cryptography, and has pointed out ſome of the beſt means hitherto ſuggeſted for deciphering ; but he has not aimed at giving many new ciphers, nor has he endeavoured to ſhew how many ways a ſkilful writer might prevent the diſcovery of even an intention to deceive. He is confident, however, that ciphers may be conſtructed, of a much ſuperior kind to any he has met with : more ready in execution ; more ſimple in their principle ; more intricate to diſcloſe ; and (in ſome examples) not liable to ſuſpicion.

It only remains at preſent to explain the nature of *Plate* III. and the lower part of *Plate* II.

The muſical writing, on *Plate* II. *fig.* 5, containing the words, " Let me know you are ſafe," &c. was compoſed and publiſhed by an author of no ability in muſic ; and the ſpecimen is here added, only to ſhew how puerile any common endeavour of that kind muſt appear to a judge of harmony : ſo that this propoſal, which has been much vaunted and recommended by Mr. Thickneſſe, is never likely to prove of extenſive practical utility.

Fig. 6, *Plate* II. repreſents one of the various modes of cryptography invented by the writer of this article. In its preſent form, it is not difficult to decipher, but is more ſimple and regular in its ſtructure than any of the Iriſh Oghams ; and, by an artifice exemplified in the next plate, which conſiſts of dots inſtead of ſtrokes, it may be rendered abſolutely inſcrutable.

Plate III. exhibits a perfectly new plan of ſecret writing, where there are only three dots (over the line, upon it, and under it,) repreſenting eighty-one letters or figures, conformably to the alphabet engraved upon the ſame plate. This method is capable of a ſurpriſing variety, but, in every variety, ſhall ſeem to be the ſame writing ; it is alſo practiſed by letters and figures, or words, or by all mingled together, without any apparent difference in its form. The reader will never diſcover any thing here beſides a ſimple dot in three poſitions, and cannot tell whether one, two, three, or more of them, compoſe each character. The inventor preſumes to think, that this contrivance is deſerving the attention of ingenious men, and might be a very advantageous acquiſition in the foreign ſecretary of ſtate's office : but, it would be incompatible with his feelings, to ſubmit any ſuch propoſal to the judgment of inferior clerks, who perhaps know nothing beyond the mechanical uſe of ciphers, and are totally unqualified to appreciate the merits of a ſcientific invention. At preſent he has, therefore, not choſen to divulge the principle of this cipher to any perſon living.

The following paragraph gives the explanation of the dot-writing on *Plate* III. with the interpretation of the two ſucceeding examples ; and alſo, in Italic letters, it expreſſes the author's name, profeſſion, place of reſidence, and the date of the year : theſe four different ſpecimens are all deciphered by ONE KEY, which is engraven at the top of *Plate* III. and it would have been eaſy to have given ſeveral hundred more varieties, to be likewiſe deciphered by the ſame key.

The art *of* writing in *c*ipher h*as* *been* ſt*udie*d by me*n* of *t*he gre*a*t*est* t*ale*nts an*d* r*a*nk in *every* civil*ized* country ; bu*t* am*o*ng the vari*ous* *c*ip*hers* whi*c*h have b*ee*n *made* public, we *h*ave neve*r* ſee*n* any tha*t* ar*e* exempt *from* *cons*iderable *objections*. Great care has been taken, in a former part of this article, to exhibit the peculiarities of the English language, and to point out the most approved means of deciphering any secret writing composed alphabetically: and, "such is the craft of man," says a modern author, "that it is scarcely possible for a letter in cipher to be written so as not to be deciphered, without any clue but a close application to the letter itself; and that too, though it were written in a language the decipherer does not understand." This author has only re-echoed the words of Mr. Falconer, and seems to believe he had even arrived at the ne plus ultra of his art; but, to shew that the writer of this article entertains a very different opinion, and that he challenges all the scrutinizing powers of man, these few specimens are here adduced. The two former, as has been already stated, contain the same internal sense as the dot-writing, and are explained by the same key. Although the key and explanation may serve to develope the principle on which this cipher is constructed, the writer has nevertheless hazarded making a discovery, by adding this one example more; wherein the involved sentiment is expressed by points, and which is also decipherable by the same key as the other specimens.

The present mode of corresponding, as well as the preceding, may be conducted with a triformed alphabet without any suspicion of a cipher being employed. The words represented by the points, in this example, may be found in the paragraph itself; so that the student will not have to look far for an interpretation of its contents. If, after such an unprecedented challenge, and so many helps towards an explanation, the reader still cannot develope this cipher; he ought to concede, that "the craft of man" is inadequate to the task of deciphering it "without any clue."

Before the student attempts to decipher the above specimens, or the dot-writing on *Plate* III. it may be proper to inform him, that the alphabet by which these paragraphs were composed, is wholly unlike any other. The alphabet consists of letters arranged in eighty-one places, forming a square of nine letters deep; and it will be observed, that the letters which are most wanted in ordinary writing, are there repeated most frequently: so that it is possible to produce an immense variety in the appearance of the specimens, while that great variety shall make no real difference in their sense or internal meaning. In consequence of such a construction of this alphabet, all the rules for deciphering with which the author is acquainted, are easily and effectually frustrated. The ingenious reader must, therefore, hit upon some new mode of analysing and explaining what is written in the paragraphs alluded to.

A similar method of corresponding admits of such an arrangement of the letters, as to seem like a foreign language: this mode has not any peculiar advantage in practice, but is somewhat remarkable in the appearance of the writing. As an example—*Relieve us speedily, or we perish; for the enemy has been reinforced, and our provisions are nearly expended,* is thus written:

Sika jygam a fuva quaxo Rolofak adunabi ye, Rasc quema Lovazig arodi; Moxati Ho hyka Fagiva myne quipaxo Aukava in Onfa yani moxarico, Pangdo Spulzi Jorixa mugaro ya zangor Alsiva yival ponbine Kazeb re linthvath.

CIPHERING, or CYPHERING, is popularly used for the art of accompting; properly called *arithmetic;* which see.

CIPIERES, in *Geography*, a town of France, in the department of the Var; 10 miles N. of Grasse.

CIPOLI, a considerable town of Asia, in the kingdom of Nepal, containing about 8000 houses, and very populous. This, and other towns of the same country, both great and small, are well-built; the houses are constructed of brick, and are three or four stories high; but their apartments are not lofty; they have doors and windows of wood, well worked and very regularly arranged. The streets of all these towns are paved with brick or stone, so laid as to afford a regular declivity for carrying off the water. In almost every street of the capital towns there are

 good

good wells made of stone, from which the water passes through several stone canals for the public benefit. In every town there are large square varandas, well built, for the accommodation of travellers and the public; and on the outside of the great towns are small square reservoirs of water, faced with brick, having a good road to walk upon, and a large flight of steps for the convenience of those who choose to bathe. Asiatic Researches, vol. ii. p. 308, 8vo.

CIPONIMA, in *Botany*, Aubl. Juss. See SYMPLOCOS *ciponima*.

CIPPUS, in *Antiquity*, a little low column sometimes without base or capital, but generally bearing an inscription. The cippi served for various uses among the ancients: placed in roads with distances engraved upon them they became milliary columns, or served the purpose of indicatory hermas. They were used for land-marks, and when the circuit of a new city was traced with the plough, cippi were placed at equal distances, on which sacrifices were offered, and which marked the situation of the towers.

The cippi found in sepulchres have been often taken for altars, on account of their form and ornaments, especially when the inscription has not contained an epitaph, properly speaking. The distinction is, however, very slight, as these cippi were consecrated to the infernal deities, and to the manes in particular; and they are even sometimes excavated in the upper part, in the form of a bason or crater. Fabretti mentions a number of cippi perforated from top to bottom, to receive libations in the manner of some altars. Hottinger has an express treatise of the cippi of the Jews, "De Cippis Hebræorum;" wherein he takes cippus for the tombstone of a defunct.

CIPPUS was also used in antiquity for a wooden instrument wherewith criminals and slaves were punished; being a kind of clog, or stocks for the feet.

CIPPUS, in *Entomology*, a species of PHALÆNA-*Bombyx*, with brown wings and three green spots, found in Surinam.

CIPRANDI *of Milan*, in *Biography*, a serious tenor singer, with much taste and feeling, arrived here in 1755, during the high favour and opera regency of Mingotti. He remained here a considerable time, for we find his name in the dramatis personæ of our lyric theatre in 1764 and 1765, with Manzoli, when, in the opera of Ezio, he was deservedly very much applauded in Bach's charming air, "Non so dondi viene," originally composed for the celebrated tenor, Raaf. And at Milan, in 1770, it has been recorded by travellers, that he sung in the churches on great festivals, in a manner far superior to the rest of the choral performers. Indeed, his cast of parts has seldom been better filled by subsequent tenor singers.

CIPRIAN RORE, or, as the Italians call him, *Cipriano di Rore*, one of the most voluminous and renowned composers of the sixteenth century, was born at Mechlin, in Flanders, 1516. In the title-page of a book, published at Venice, 1549, he is called the scholar of Adrian Willaert. In the preface to the Canti Carnascialeschi, published at Florence, 1559, he is called *Cantore;* as if he had been merely a *singer* in the service of the house of Medicis. However, he seems to have spent the greatest part of his life in Italy, as a composer; in which character he is mentioned with great respect by Zarlino, Vincenzo Galilei, Pietro Pontio, and almost every Italian musical writer of his time. And, after having been successively maestro di capella to the duke of Ferrara, the republic of Venice, where he was the immediate predecessor of Zarlino, and the duke of Parma, he died at the court of that prince, 1565, aged forty-nine. His motets and madrigals were first published at Venice, 1544, and again, together with his masses, and many other works, after his decease, in 1562 and 1565. His "Cantiones Sacras," or motets, were likewise published at Lovain, 1573.

CIPRIANI, GIOVANNI BATISTA, was of a Pistoiese family, but born in Florence, according to Heinecken, in 1732. At a very early period of life he evinced great facility and taste in his drawings, many of which, in the manner of Gabbiani, are still to be met with at Florence. Lanzi mentions two juvenile performances of Cipriani in oil, in the abbey church of St. Michele near Pistoia; one representing St. Tesauro, the other St. Gregory the 7th, observing at the same time, that though he drew much he painted but little.

In 1750, he went to Rome to complete his studies, and soon afterwards came to England, where he was chosen a member of the Royal Academy, and lived much respected during the remainder of his life. Amongst the first works which Cipriani painted after his arrival in this country, was a room decorated with poetical subjects, in the house of the late sir William Young, at Standlynch in Wiltshire. The intimacy, however, which subsisted between our artist and Bartolozzi, the celebrated engraver, contributed not a little to encourage him in his fondness for sketching, and to deter him from the more laborious task of oil painting; what the one drew the other etched, and thus the elegant designs of Cipriani were rapidly disseminated over Europe. It might, perhaps, be said, that throughout his works there was too evident a similarity, as the same forms, the same characters, the same expressions, so frequently pervade them, but his drawing is at all times correct and graceful. Some of the few pictures which he left, are at the seat of Mr. Coke, at Holkham, in Norfolk. He died, much regretted, in the year 1790. Lanzi Storia Pittorica. Fuseli.

CIPSOLA, in *Geography*, a town of European Turkey, in the province of Romania: 24 miles N.N.W. of Gallipoli.

CIPURA, in *Botany*, Juss. p. 58. a genus formed by Aublet for a plant found in Guiana, of which he gives the following description. *Cal.* tubular at the base, superior; border six-cleft; three inner ones alternating with the others, and only one third as large. *Stam.* three, inserted into the tube. *Pist.* Style thick, trigonous; stigma three-lobed. *Root* tuberous, tunicated. *Root-leaves* sword-shaped, nerved, sheathing. *Flowers* on a scapus, in a kind of terminal spike, spathaceous; lower spathes longest. Aub. Guian. tab. 13. La Marck has adopted this genus, and copied Aublet's figure, Illust. Pl. 30. with the following generic and essential characters expressed in the language of the Linnæan system. Class and order, *triandria monogynia*.

Gen. Ch. *Cal.* none, spathe oblong, membranous, concave, involving the flower. *Cor.* six-petalled; three outer petals larger, egg-shaped; three inner ones alternate, three times less. *Stam.* Filaments three, very short, inserted into base of the corolla; anthers oblong, erect. *Pist.* Germ inferior, oblong, trigonous; style thick, triangular; stigmas three, petal-shaped, acute. *Peric.* Capsule oblong, angular, three-celled. *Seeds* many, angular.

Ess. Ch. Corolla six-petalled; three inner ones smaller, capsule inferior, three-celled. Illust. p. 107.

Sp. C. *paludosa*. *Root*, a round fleshy bulb. *Stem* six inches high or more, slender, firm, furnished near the top with two leaves, and sometimes with other short ones. *Leaves* more than a foot long, surrounding the bulb at their base, narrow, acute, thin, striated. *Flowers* white, or blue. Encyc.

Obs. Linnæus would have called the three interior petals, or rather segments of the border, a nectary.

CIRCADA, a tribute anciently paid to the bishop or archdeacon, for visiting the churches.

CIRCÆA,

CIRCÆA, in *Botany*, (Κιρκαια, Diosc.; *Circea*, Plin.; so called from the enchantress, Circe); Tourn. Cl. 6. §. 9. gen. 2. Linn. gen. 24. Schreb. 31. Gært. 134. Juss. 319. Vent. vol. iii. 310. Enchanters nightshade. Class and order, *diandria monogynia*. Nat. ord. *aggregatæ*, Linn. *onagræ*, Juss.

Gen. Ch. *Cal.* Perianth two-leaved; leaves egg-shaped, concave, reflexed, coloured, deciduous. *Cor.* Petals two, spreading, equal. *Stam.* Filaments two, capillary, erect; anthers roundish. *Pist.* Germ top-shaped, beset with little hooked bristles, two-celled, two-valved, opening from the base towards the top. *Seeds* solitary, oblong, narrow at the bottom.

Eff. Ch. Corolla two-petalled. Calyx two-leaved, superior. Capsule two-celled. Seeds solitary.

Sp. 1. C. *lutetiana*, With. Sp. Pl. Mart. Lam. Willd. Flor. Dan. tab. 210. Lam. pl. 16. fig. 1. Gært. tab. 24. Eng. Bot. 10156. Common enchanters nightshade. "Stem erect; leaves egg-shaped, finely toothed, opaque, pubescent." Dr. Smith. *Root* perennial, creeping so much as not to be easily extirpated. *Stem* erect, or procumbent, according to its situation, a foot and a half high, not much branched. *Leaves* opposite, dark green. *Flowers* white or reddish, in terminal racemes; peduncles, spreading, at length reflexed; calyx-leaves scarcely membranous, egg-shaped, reflexed, coloured. *Capsule* roundish, beset with little hooked bristles, by which, separating entirely from the stalk, it sticks to the coats of animals. One of the seeds frequently abortive. A native of England and other parts of Europe, in shady lanes under moist hedges. In gardens it is often a common weed, flowering in June and July. 2. C. *alpina*, Linn. Sp. Pl. Mart. Lam. Willd. Lam. pl. 16. fig. 2. Eng. Bot. 1057. (Solanifolia circæa alpina, Bauh. Pin. 168. Moris. tab. 34. fig. ult.) Mountain enchantress nightshade. "Stem ascending; leaves heart-shaped, shining; calyx membranous." Dr. Smith. β. C. alpina, Flor. Dan. 256. Curtis Flor. Lond. Fasc. 3. tab. 3. (C. intermedia, Ehr. 101.) *Root* creeping. Whole plant less pubescent than the preceding species. *Stems* low, diffuse at the base, with red joints. *Leaves* tender, of a pleasant yellowish green colour, toothed-serrated; petioles membranous-angular. *Flowers* of a vivid red colour; racemes often numerous, short, terminal and axillary; calyx membranous, white, with a red tip. Dr. Smith. A native of Sweden and other northern parts of Europe; of Scotland and Cumberland, &c. in the north, but not in the south of England. The variety β is erect, about the size of C. lutetiana, in other respects resembling the present species. A native of shady, but open woods, by the river side of Matlock in Derbyshire. We have found it, but sparingly, in similar situations in the neighbourhood of Leeds.

CIRCÆUM, in *Ancient Geography*, *Irké*, a town of Asia in the Colchide, seated on the left bank of the Phasis, W.S.W. of the Tyndaris.

CIRCÆUM *Promontorium*. See CIRCEII.

CIRCAR, in *Geography*, a name given in Hindoostan to a tract of country, which, according to the statement of major Rennell, is not very dissimilar to that of a county in England; few of the circars being of less extent than the largest English counties. The famous Acbar, in the 16th century, began by dividing Hindoostan Proper into 11 soubahs or provinces, some of which were in extent equal to large European kingdoms; and the soubahs were again divided into circars, and these subdivided into purgunnahs, corresponding, as major Rennell suggests, to kingdoms, or viceroyalties, counties, and hundreds, in English terms. See SOUBAH.

CIRCARS, *Northern*, denote five circars or provinces, so denominated originally from their position in respect to Madras, on which they depend. These Circars are Cicacole, Rajamundry, Ellore, Condapilly, which are in the possession of the English; and Guntoor, which is in the hands of the Nizam. The first four occupy the sea-coast from the Chilka lake on the confines of Cattack, to the northern bank of the Kistnah river; forming, comparatively, a long, narrow slip of country, 350 miles long, and from 20 to 75 wide. The nature of the country is such, as to be easily defensible against an Indian enemy; as it has a barrier of mountains and extensive forests on one side, and the sea on the other: the extremities only being open. Its greatest defect is in point of relative situation to Bengal and Madras; it being 350 British miles from the first, and 250 from the latter: so that the troops destined to protect it cannot be reckoned on, for any pressing service that may arise at either presidency. The Circars, in point of strictness, appertain partly to Golconda (or the Deccan) and partly to Orissa; and are held of the Nizam, on condition of paying him a stipulated quit-rent. In consequence of the wars which terminated, after much bloodshed and assassination, in 1754, by fixing Mahomed Ally in the government of Arcot, and Sa abidjung, son of the late Nizam-al-Muluch, in the soubahship of the Deccan, the English gained the point of establishing their security, and their influence, in the Carnatic; and the French, in addition to the solid advantage of getting possession of the northern circars, gained the splendid but uncertain privilege of influencing the councils of the Nizam, by attending his person with their army. This latter privilege was of short duration; for while M. Bussy, at the head of the French army, was at Sanore, in the western quarter of the peninsula (in 1756) a quarrel with the minister of the soubah of the Deccan occasioned the dismission of the French. They were then compelled to retreat through an enemy's country for near 300 miles, till they reached Hydrabad, where they fortified themselves, and waited for reinforcements. At Hydrabad the quarrel was compromised; and the following year (1757) and part of the next were spent by M. Bussy in reducing the refractory Rajahs, or Zemindars, in the northern circars, and in assisting the soubah to execute his own plans. In the midst of these transactions, M. Bussy was suddenly recalled into the Carnatic; and the soubah was left at full liberty to accede to the proposals of the English. The Circars, the fruits of M. Bussy's wars and negotiations in the Deccan, and which had been obtained in 1753, yet remained with the French; but colonel Clive, at this time governor of Bengal, with that promptitude and decision which so strongly marked his character, seized on them with a force from Bengal, in 1759; although they were defended by a much superior force; and the French were deprived of resources to carry on the war in the Carnatic. Thus the French not only lost all their possessions in the Carnatic, but in every other part of India: so that their political existence may be said to have begun in 1749, and to have ended in 1761, by the capture of their principal settlement, Pondicherry. When the French took possession of the five Circars in 1753, they were valued at about 43 lacks of rupees per annum. The English never possessed Guntoor, which was estimated at near 7 lacks of the above sum; so that 36 lacks (about 360.000*l.*) should be taken for the true value of the English possessions in the Circars. In 1784, they were reckoned to produce about that sum. It would appear, that the Nizam, by retaining Guntoor, had more than an equivalent for the peihcush or tribute, which is 5 lacks per annum. However, Guntoor has since been ceded to the East India company;

company; and it is justly reckoned an important accession. See GUNTOOR.

CIRCASSIA, a country of Asia, bounded on the north by the river Don; on the east by the Caspian sea, and the mouths of the Volga; on the south by mount Caucasus and the Black Sea; and on the west by part of the Black Sea and the lake of Azof. It was formerly governed by several independent princes: but since the convention of 1783, it is now almost wholly subject to Russia, and included in the government of Caucasus. See CAUCASUS and *province* of CAUCASUS. The Circassians, or, as they are called by the Russians, Tcherkessians, are formed of the relics of the mingled swarm, usually comprehended under the appellation of Alanians, who settled on the northern side of Caucasus soon after the Yazamates. The Circassians, or races collaterally related to them, as for example, the Zichians, and Auchasians, gradually took possession of the southern regions adjacent to the Cuban. During the empire of the Chazares, the Byzantine emperors appear to have exercised, or at least to have claimed, a sort of paramount supremacy over this nation, because the Zichians were reckoned among their provinces. When the Russians erected a state upon the island and in the city of *Taman* (which see), the Zichians were tributary to them; but, after the Komanes or Polootzes had conquered the north-eastern part of the Cuban, they put the Circassian stems in possession of the southern and western, and extended themselves afterward continually farther and farther to the north. In 1277, the Zichians were compelled to yield to the victorious arms of Mangu-Timur and Nogay. However, both they and the Circassians remained truly independent in the upper regions of the mountains. They were even, at that period, still in possession of the whole eastern coast of the sea of Azof as far as the Don. They rendered themselves masters of the city of Kertsch in the Crimea, made frequent incursions into that peninsula, and into other European countries, formed the basis of the then rising Caucasian tribes, and founded in Egypt a famous dynasty. At the close of the 14th century, when the Zichians suffered much by the famous victories of the great Timur, and afterwards asserted their liberty with energy and effect against the Ottomans, the Circassians remained unsubdued. Although in the middle of the 16th century the czar Ivan II. reduced the Circassians under his dominion, it was only for a short period; and the Circassians of Cuban maintained themselves as well on the Don as on the Cuban. There they formed, in conjunction with the Russians, the state of the Don-Cossacks; where they retained possession of all the islands of the Lower Cuban, the whole of its southern banks, and the regions contiguous to the Euxine. These southern people, however, were compelled, in the 17th century, to acknowledge the paramount lordship of the khan of the Crimea, although they were governed by beys of their own nation. The tribute which they paid to the khan consisted chiefly in beautiful youths and virgins for the supply of his Harem. At the commencement of the 18th century, the Circassians revolted against this humiliating tribute, and put themselves under the protection of the Porte, without becoming subject or tributary to it. About the middle of this century, 29 Circassian stems, according to Peyssonel's account, were under the khan of the Crimea, who could easily bring into the field 100,000 men. But few of these stems were really his subjects: the south-eastern lived almost in an entire independence, or acknowledged only with reservation the sovereignty of the Crim. At the peace of 1774, some other districts of the Circassians were ceded to the khan; but on the seizure of the Cuban in 1783, the stems of this people in subjection to the khan of the Crimea, fell to the Russian empire. The separation of the Asiatic districts, usually comprehended under the general appellation of Circassia, was, on that occasion, recognised to be made by the river of Cuban. Concerning the present state and the population of the Russian Circassians, little can be authentically ascertained, as no enumeration has been hitherto instituted in those parts. All the districts and stems in the Cuban are properly Russian subjects, inhabiting the islands of the Lower Cuban, the whole southern shore of that river up to its source, and the regions bordering on the Euxine as far as Auchasia. The Circassians in both the Great and Little Kabarda are reckoned only among the vassals of Russia. The sovereigns of that empire style themselves, since the conquest of the Upper Kabarda by Ivan II. lords of the Kabardinian countries of the Circassians and mountain-princes. This seems not to have been a mere title, for though this conquest was afterwards lost, yet the princes of the Great and Little Kabarda, several times between the years 1740 and 1750, took the oaths of fealty to Russia.

The Circassians who inhabit the parts of mount Caucasus more advanced than the Abassinians that occupy Great Abassa, and who have spread into the contiguous beautiful plain, whence they have expelled or subjugated the former natives, are represented by Pallas, in his "Journey into the Southern Departments of Russia," as a warlike nation. They are, he says, a species of knights, observing a complete feudal system among one another, and towards their subjects; and in this view of them, supposing that the chiefs and nobility alone constitute the nation, that their subjects are almost all slaves of conquered nations, who have adopted the language of their masters, and as such are mildly treated, and that a free courageous knighthood cannot endure a foreign yoke, without the greatest repugnance; we may judge with greater indulgence concerning their aristocratical constitution, their constant wars, and their resistance formerly against the khan of the Crimea, and now against Russia. It is fortunate that their internal feuds, and the division of the power of this heroic race among a number of petty chiefs, render them less formidable; and it were to be wished, that, without impairing their bravery, they could be brought to be good vassals, and somewhat accustomed to order; in which case, they would turn out as resolute light cavalry as ever took the field. The part of this nation which concerns Russia, is that which is settled in and near the Caucasian line, inhabiting, as we have already observed, the larger and smaller Kabarda. The Kabardinians hold themselves to be of Arab origin; perhaps they are the remains of the armies formerly sent by the khalifs against Caucasus. Others deduce them from the Mamelukes. General tradition, confirmed by still subsisting names, shews that they formerly inhabited the Crimea. The nobles are divided into ancient noble knights and nobles of nobles.

The Circassians in general, and particularly the Kabardinians, live in villages, which they quit from time to time on account of the accumulation of filth, their insecurity, or other inconveniencies. They carry with them their best wood for spars and wheel-wright's work, and burn the rest. They then seek some other commodious spot. When they build at any distance from water, they conduct a canal by embankments from the nearest brook, in which business they are as expert as the Crim Tartars. They build their habitations near together, in one or more circles or parallelograms; so that the area within constitutes the common spacious yard for cattle; this has only a single gate, and is surrounded, and in some sort defended, by the houses. The men usually dwell in a separate apartment, and do not willingly

ingly appear with their wives in the prefence of ftrangers. The Circaffians are, generally fpeaking, a handfome people. The men, particularly the chiefs, are commonly tall, flim, very flender above the hips, fmall in their feet, and ftout in their arms. They have for the moft part a Roman and martial air, but in fome a mixture of Nogai blood is vifible. The women are not all Circaffian beauties, but they are generally well made, fair-complexioned, dark-haired, regular in their features, and among them are to be obferved more beauties than frequently occur among an uncivilized people.

They are very cleanly in their villages and houfes, as alfo in their clothes and diet. It is a known fact, that a corfet, or broad belt of undreffed leather, is fewed (among more diftinguifhed perfons, it is fixed with filver clafps), from below the breafts to the hips. This girdle muft not be laid afide till the wedding night, when the bridegroom himfelf removes it with a fharp fword, often at confiderable hazard to the bride. For the fake of their fhape alfo, the girls are kept low, being fupported only with a little milk and cake. According to the Circaffian, and alfo to the Turkifh ideas of beauty, a woman fhould be drawn very fmall over the hips, and have the belly projecting downwards.

The men alfo endeavour to render the waift exceffively flender, by the belt to which the fabre is appended. They have all very fmall feet, from inclofing them as tight as poffible in focks of morocco leather, which give them the air of dancers, and with which they fit on horfeback.

The chiefs and knights have no bufinefs but war, pillage, and the chafe. They live like gentlemen, ramble about, frequent caroufals, or concert freebooting fchemes. The knights keep the people in order, and are in nothing bound to the chiefs or princes, except in military fervice. The peafants or fubjects, who yield blind obedience to the princes and knights, and hold life and property at the will of the former, are tranfmitted by inheritance; but no inftance has occurred of their being fold. Thefe people, and the flaves taken in war, who afterward fall into the clafs of the commonalty, plough the land with large ploughs, feed the herds, carry wood, build the habitations, reap, and make hay, which in winter is commonly eaten on the fpot. In harveft they are affifted by the women and grown-up girls, who are not kept fo clofe as among the Crim Tartars.

Among the peafants, every man muft mow and carry hay for three days, for the nobleman or prince; cut and carry wood three days; and deliver feven facks of millet for every ox that he poffeffes. A bridegroom of this clafs muft alfo give two cows and two oxen to his lord. The inhabitants of the mountains, whom the Circaffian princes have rendered tributary, give for each family a fheep, or its value. Every one who has a flock, be it great or fmall, muft give a fheep in fummer, at the time of encampment, to the prince; for which the latter keeps open table.

In general, the prince, although he is bound by no laws, muft endeavour to deferve the love of his fubjects, and their attachment in war by liberality, hofpitality, and kindnefs. He may ennoble a deferving fubject. On occafion of great undertakings, he affembles the nobles, and by them the decifions of the affembly are notified to the people. The number of Circaffians it is difficult to determine. Reckoning the tribes beyond the Cuban, they amount to a confiderable power; which, confidering their bravery and military fpirit, would be dangerous, were it not divided among fo many difagreeing princes.

The two oppofite cuftoms of hofpitality and the *lex talionis*, are held facred among the Circaffian knighthood, and moft other people of Caucafus. The former is reduced to fixed principles; and every one who finds himfelf under their protection is perfectly fecure againft all moleftation. The hoft guards him with his own and his people's life, furnifhes him with an efcort, is anfwerable for him to his kinfmen; and the murder of, or infult towards the gueft, is punifhed as feverely as in the cafe of a relative. A ftranger who puts himfelf under the protection of a woman, or can touch the breaft of a woman with his mouth, were he an enemy, or even the murderer of a kinfman, is fpared, and protected as if he were a member of the family.

The *lex talionis* is juft as confcientioufly practifed among the Circaffians. The next heir, or neareft in blood, even though at the time he be a child, muft take vengeance either openly or by guile, for the murder of a kinfman, if he will not be expelled from fociety. The price of blood is called *Thlil-Uefa*. Princes, however, and nobles, accept no price, but require blood for blood.

The education of the children of the princes is calculated, from the earlieft infancy, to ftifle every feeling of affection. Sons and daughters are delivered on their birth to fome nobleman, often not one of the richeft. The parents, particularly the father, never fee the boy till he is capable of bearing arms, nor the girl till after fhe is married.

The origin of this cuftom of committing the education of all male children to ftrangers, in preference to parents, whilft (as fome fay) females are brought up by the mothers; and alfo that which prohibits hufbands, under pain of infamy, from publicly converfing with their wives, fo that the two fexes are divided into two diftinct communities, cannot be traced to any diftant nation. But if we fuppofe them to exift at an early period in mount Caucafus, they may, perhaps, in fome meafure, account for the fabulous defcription of the Amazons and Gargarenfes, who are placed by ancient geographers in the country now occupied by the Circaffians. See AMAZONS.

The Circaffians practife agriculture, and particularly pafturage. They principally fow millet, of which they not only make various preparations for food, but alfo a liquor which they call *bauthups*. They likewife cultivate maize, which, on journeys and expeditions, ferves for aliment in cafe of need. They plant feveral garden vegetables. The women make a very ftout yarn out of the wild hemp, but they have not the art of weaving linen cloth.

The care of horfes conftitutes, as one may expect among roaming horfemen, the moft important department of their rural economy. To this they attend with as much care and zeal as the Arabs. They aim not merely at beauty, but alfo at ftrength, ability to endure hunger and fatigue, and fpeed; fince the fuccefs of their expeditions depends on the quality of their horfes. Almoft every princely and knightly family boafts of a particular breed of horfes, and burns their mark upon the hips of the true bred foals. In this refpect they are fo confcientious, that he who fhould fix the mark of a noble race on an ordinary foal, muft pay for the fraud with his life.

The language of the Circaffians is common to them with the other neighbouring Tartars, although the chief people among them are not ignorant of the Ruffian.

It appears from a vocabulary prefented to us of the languages or dialects of the Caucafian nations, by Mr. G. Ellis in his "Memoir of a Map of the Countries comprehended between the Black Sea and the Cafpian" (1788), that many of the Circaffian and Caucafian words are nearly the fame as thofe of the uncivilized inhabitants of America. Hence thofe who incline to the opinion of Hornius, and others,

others, who have maintained, that America was originally peopled by colonies from Asia, particularly from Scythia or Tartary, deduce an argument in favour of their opinion.

Their reli[illegible]n is Paganism: for though some of them were formerly Christians, and others Mahometans, and they practise circumcision, they have neither priest, alcoran, nor mosque, like other Mahometans. Every body here offers his own sacrifice at pleasure, for which, however, they have certain laws, established rather by custom than by any positive com[illegible]: their most solemn sa[illegible] their nearest friends, upon which occasi[illegible]men meet in the field, to be present at the offering, which is an he-goat; and having killed, they flay it, and stretch the skin with the head and horns on it, upon a cross at the top of a long pole, placed commonly in a quickset hedge (in order to keep the cattle from it), and near the place the sacrifice is offered, by boiling and roasting the flesh, which they afterwards eat. When the feast is over, the men rise, and having paid their adoration to the skin, and muttered over certain prayers, the women withdraw, and the men conclude the ceremony with drinking a great quantity of aqua-vitæ, and this generally ends in a quarrel before they part.

The Circassians have few manufactures. The points of their arrows are the only articles of iron, which they work up themselves. They make, indeed, some very fine cloths, and felt for cloaks, which is singularly light and durable; and to these we may add a few articles of leather, embroidered housings for horses, &c. Their beautiful coats of mail are brought from Persia, and their fire-arms from Kubescha. The principal traffic of the Circassians consists in slaves, honey, wax, skins of cattle, deer, and tigers. They have no money, and their whole commerce is carried on by exchange.

CIRCE'. See the next article.

CIRCELLI, or Circello, Monte, a cape and promontory of Italy, near Naples, sometimes erroneously described as an island, but connected with the continent by a neck of land. It is a high mountain, at the southern extremity of the Pomptine marshes in the Ecclesiastical state, renowned in fable for having been the residence of the enchantress Circé, who transformed men into brutes, and whose connections with Ulysses are described by Homer in the 10th and 12th books of his Odyssey.

The ancient *Circeii* included both a town and promontory situated in that part of Latium, which had belonged to the Volsci, and which lay nearly at an equal distance from Rome to the N.W. and Naples to the S.E. on the western side of the mountain. The coast was subject to the lashing of furious waves, and presented a variety of steep rocks, on the most elevated of these was placed the temple of Circé, the daughter of the Sun. The port was surrounded by a long wall, and it had been formed into a lake situated on the west. Circeii, about 24 years before the expulsion of Tarquin, became a Roman colony. In the time of Cicero, the temple of Circé subsisted. The outline of the fable is as follows: Ulysses, landing upon this promontory, sends a party to explore the country. They arrive at the palace of Circé, who courteously invites them to enter; and all but Eurylochus comply. She sets before them a mixture of meal, cheese, honey, and Pramnian wine; the same composition as Nestor prepares for the wounded chiefs in the Iliad. With this she mixes poisonous drugs, and after they have all partaken of the refection, she strikes them with a rod, and they are instantly transformed into swine. In this part of the fable nothing has the appearance of intemperance or gross sensuality. On the return of Eurylochus, however, who, not knowing the fate of his companions, concluded that they were all murdered, Ulysses bravely resolves to set out alone, in order to explore the event. In the way, he is met by Hermes in the shape of a youth, who informs him of the nature and mode of Circé's enchantments; and presenting him with a root, called "Moly," as a preservative, directs him, on being touched with the rod, to draw his sword and threaten Circé with death. "Then (says he) she will invite you to her bed, and do not you on [illegible] offer, since it will conciliate her kind[illegible] with an oath not to plan any farther mischief against you." Ulysses acts in all points as he was commanded. Ulysses stays a whole year with Circé, sharing her bed, and making merry with her good cheer, without ever thinking of Ithaca, till his men remonstrate with him, and urge his return. An ingenious writer suggests, that Homer, in the story of Circé, had no other end in view, than in that of the Cyclops, the Læstigons, and various others; namely, to gratify the passion for novelty and love of wonder belonging to all ages and all readers, by introducing into the travels of his hero, all those extraordinary narrations, which he had learned from tradition, or the reports of mariners. This purpose, so natural in a poet of a rude age, will account, not only for the strange matter intermixed with many of his fables, but for their being introduced at all. He who looks for any better reason for many things that he will find in the early writers, will only sacrifice his own judgment to their reputation. Aikin's Letters to his Son, p. 62.

CIRCELLIONES. See Agonistici.

CIRCENSES *Ludi*, Circensian *games*, or *games of the* Circus, a general term under which were comprehended all combats exhibited in the Roman circus of what kind soever; whether on foot or horseback, or in a car; wrestling, or boxing; with swords, pikes, darts, or arrows; against men, or against beasts; on the ground, or aboard vessels.

There were few, except slaves, that gave the people this cruel pleasure: it was an exercise that would have disgraced people of any account. See the article Gladiators.

Some say the Circensian games were so called from the Latin *circumenses*; because they were held in a place encompassed round with naked swords, that the combatants might not have an opportunity of escaping.

At first they are said to have been exhibited on the brink of the river Tyber, and the ground encompassed toward the land with naked swords.

Most of the feasts of the Romans were accompanied with Circensian games; and the magistrates, or other officers of the republic, frequently presented the people with them on other occasions. The grand ones were held for five days, commencing on the 15th of September. See Circus.

CIRCERELLUS, in *Ichthyology*, a name used by some authors for a fish usually called *ammodytes*, or the *sand-eel*.

CIRCESIUM, Circessus, or Cercusium, *Kerkisieh*, in *Geography*, a town of Asia, in Mesopotamia, at the confluence of the Aboras, or, as Xenophon calls it, the Araxes, with the Euphrates. In the time of Dioclesian this town was strongly fortified.

CIRCIA, in *Ornithology*. See Anas.

CIRCIDIUS, in *Ancient Geography*, a river of Corsica, the mouth of which is placed by Ptolemy on the western coast of the island.

CIRCIGNANO, Niccolo, called *Pomarancio*, in *Biography*, an historical painter of considerable eminence, who was born at Pomarance, a small town in the vicinity of Volterra

terra in Tuſcany, about the year 1516. Vaſari ſpeaks of him as a young man of ability, but without informing us who was his maſter. He is conſidered one of the beſt of the artiſts employed by Gregory XIII. and Sixtus V. upon the extenſive but hurried performances in the Vatican. In his freſcoes in the cupola of the church of S. Pudenziana at Rome, he appears ſuperior to the manneriſts of his time. Many of his other works at Rome are mentioned by Baglione: amongſt the moſt eſteemed is a coloſſal figure of Chriſt giving the benediction, ſurrounded by angels; a freſco in the church of S. Giovanni e Paolo. His native city and Loretto poſſeſs other of his performances. He died in Rome at the age of 72, about 1588. Baglione. Lanzi, Storia Pittorica.

Circignano, Antonio, called *Pomerancio*, was the ſon of the preceding artiſt; but, beſides the inſtructions of his father, he received great benefit from the leſſons of Chriſtoforo Roncalli his countryman, one of the beſt artiſts of his time. Antonio Circignano is little known by his works at Rome; but Città di Caſtello, where he ſpent ſome of the beſt years of his life, poſſeſſes ſeveral of his pictures; one of which a conception, (*concezione*,) at the church of the Conventuali, ſeems an union of the ſtyle of Roncalli with that of Baroccio. He died, aged 60, in the pontificate of Urban VIII. Pilkington ſays he was born in 1560. Baglione. Lanzi, Storia Pittorica.

CIRCINALEA *Folia*. See Leaf.

CIRCINIUM, in *Ancient Geography*, a city of Aſia, in Magneſia, ſituated at the foot of mount Oſſa, near the lake Bœbis, between Sothuſſa and the Macedonian ſea.

CIRCITOR, in the *Ancient Military Diſcipline*, an officer among the Romans, who went the rounds, after having received his orders from a tribune to viſit the ſeveral poſts, and ſatisfy himſelf that the ſentinels had not quitted them nor fallen aſleep.

Circitor is alſo uſed to ſignify a hawker, or pedlar, who goes about from place to place to vend his goods.

CIRCIUM, in *Botany*. See Cirsium.

CIRCLE, the name of various *aſtronomical inſtruments*. It will probably appear a paradox to ſome of our readers, to be told, that aſtronomical *obſervations* were made, in various parts of the world, many centuries before aſtronomical *inſtruments* were invented. The obſervations, to which we allude, were ſuch as related to the riſings and ſettings of the ſtars in different latitudes and in different ſeaſons of the year; to the claſſing of cluſters of ſtars into imaginary figures, called in the Engliſh language conſtellations; to the reſpective aſcenſions and deſcenſions of the circumpolar ſtars; and to eclipſes of the ſun and moon, as well as to occultations of the ſtars and planets, or *wandering* ſtars, by the moon. Hence aroſe the terms *heliacal*, *coſmical*, and *achronical* riſings and ſettings of the ancient authors, and various other terms in aſtronomy, which are retained to this day. Theſe obſervations, made at firſt by ſhepherds and herdſmen, ſimple as they were, were not only ſerviceable in determining the ſeaſons ſuitable for the different operations in huſbandry, but afforded data for aſcertaining the lengths of the ſolar and lunar periods, with a degree of accuracy which aſtoniſhes the modern aſtronomer. Before we proceed to deſcribe the circular inſtruments uſed in aſtronomy and navigation at the preſent day, it may not be unintereſting to give a brief hiſtory of the inſtruments that preceded them.

The firſt inſtrument, probably, which was uſed as a meaſure of altitude, was the gnomon, many centuries after the Babylonians, the Egyptians, and the Chineſe had been accuſtomed to make celeſtial obſervations, ſuch as we have ſpoken of. The firſt mention, we believe, that is made of the term *hour*, as a portion of the day, occurs in our Bible, in the book of Daniel, chap. iii. verſe 6, under the reign of Nebuchadnezzar, about the year before Chriſt 600; and the Grecian hiſtorian Herodotus expreſsly ſays, that the Greeks learned the uſe of the pole, the gnomon, and the diviſion of the day into twelve parts from the Babylonians. Accordingly, Diogenes Laertius informs us, that Pherecydes ſet up a pole or dial in the iſland of Syra, one of the Cyclades, about the year before Chriſt 540, which, indeed, Anaximander had done previouſly, about the year before Chriſt 547, at Lacedæmon; and the Jews, in the reign of Ahaz, had known the uſe of a dial nearly 200 years before. The Roman dials, of courſe, were poſterior to theſe; the firſt that was ſet up at Rome, which was by Papirius Curſor, being, according to Pliny, (N. H. l. vii. c. 60.) about the year 461 of the building of the city, or 293 before Chriſt. The uſe of a gnomon, or ſtyle of a large dial, as an inſtrument for meaſuring altitudes of the ſun, aroſe from the circumſtance of an obſerved increaſe in the length of the ſolar ſhadow as the ſun's altitude decreaſed. Geometry by this time had begun to be greatly improved by Thales, Pythagoras, Hippocrates, Eudoxus, Euclid, Apollonius, Archimedes, and others; and aſtronomy was now cultivated in the ſchools, particularly by Eudoxus and Aratus. Plato alſo had learned in Egypt, that the ſolar year is $365\frac{1}{4}$ days; and Philolaus aſſerted the annual motion of the earth round the ſun, as did Hicetas the diurnal motion of the ſame; ſo that the obſervations which had been made ſome centuries before the Chriſtian æra, and the ſyſtems ſuggeſted by different philoſophers to explain the obſerved phenomena, muſt have diſpoſed the minds of all the early cultivators of ſcience, to avail themſelves of the uſe of an inſtrument, which afforded data for calculations, beyond what mere ocular obſervation could furniſh. The compariſon of the perpendicular height of a gnomon with the length of its meridian ſhadow, projected on a horizontal plane, ſimple as the obſervation was, afforded the means of aſcertaining the ſun's apparent meridian altitude on any day by means of the Pythagorean Theorem on the properties of the right-angled triangle. This obſervation, made on the days of the ſummer and winter ſolſtices ſucceſſively, determined the difference of the ſun's meridian altitudes on thoſe days, and conſequently the ſpace contained within the two tropics, which is juſt double the greateſt declination; hence the complement of the latitude of the place, or, which is the ſame thing, the complement of the pole's elevation, was determined with conſiderable accuracy. Thales, whoſe diſciple Pythagoras was, and who, Laertius ſays, was the real author of Euclid's 47th propoſition, uſually called the Pythagorean propoſition, was accuſtomed to meaſure the heights of the pyramids of Egypt by their ſhadow, and could foretel eclipſes; he was alſo the firſt who divided the celeſtial ſphere into zones by the introduction of five circles, *viz.* the arctic, the ſummer tropic, the equator, the winter tropic, and the antarctic circle. This diviſion of the heavenly regions into zones, divided by parallel circles, at a time when geometry was cultivated, naturally led to the taking of the latitudes and longitudes of the heavenly bodies; and it may be worthy of remark here, that the pyramids themſelves had their planes facing the eaſt, weſt, north, and ſouth points, which, therefore, might be uſed as inſtruments of obſervation. Anaximander, another diſciple of Thales, who, we have ſaid, invented the gnomon, wrote a treatiſe on the ſphere, and explained the obliquity of the zodiac; and, about 100 years after him, Anaxagoras, who ſtudied philoſophy for 30 years at Athens, wrote a book on the "Quadrature nature of the Circle." Thus, these philosophers of what was called the Ionic sect, may be said not only to have laid the foundation of astronomy as a regular science, but also, by referring the places of the heavenly bodies to certain supposed circles in the heavenly regions, to have suggested to future astronomers the most natural shape of an instrument that should be best calculated to measure their relative angular distances: we do not, however, meet with any account of circular or other instruments used by any of the philosophers of the Ionic or the Academic schools, until we arrive at the time of Hipparchus, who lived about 160 years before Christ. This astronomer collected the different observations that had been previously made; and made new ones by means of an instrument, called an *astrolabe*, which was a kind of armillary sphere, calculated at once for being used in taking observations, and for illustrating the heavenly motions when ascertained. This astronomer is said to have been the first who attempted to count the stars, and to make a catalogue of them: and was also the first who made *ephemerides*, or calculations of the relative places of the heavenly bodies, which he did to include a space of 600 years. Soon after Hipparchus, Eratosthenes, the Alexandrian librarian, measured the length of the earth's radius by a comparison of a gnomon at Syene in Upper Egypt with another at Alexandria, it having been observed that the former used to cast no shadow on the day of the summer solstice; this Eratosthenes had also an astronomical instrument constructed similar to that of Hipparchus, with which he made observations on the heavenly bodies.

We do not find any other mention of astronomical instruments until we come down to the reign of the Roman emperor Antoninus, when Claudius Ptolemæus, commonly called Ptolemy, wrote his "Almagest," or famous book on astronomy, about the year of Christ 147, which science he had learned in Egypt, though a native of Pelusium. In this work, which has also been called the "Great Syntax," and which is well known to astronomers, we find an account of another circular astronomical instrument for making celestial observations, described also by the name of *αστρολαβικον οργανον*, which, we understand, had only one large ring or plane graduated, and most likely was similar to the astrolabe described in Bion's book on the "Construction and principal Uses of mathematical Instruments;" this instrument, according to Bion's description, (see *Plate* I. *fig.* 1. of *Astronomical Instruments*,) like a common ring-dial, was made heavy, and arranged itself in such a vertical plane when suspended by a small ring, that the points *o* and *o* of the graduated circle stood at opposite ends of a true horizontal line; and a diametrical bar, turning on a pin in the centre, carried two vanes, one at each end, through which the altitude of a heavenly body might be readily taken, in degrees and parts of a degree, as indicated by the fiducial edge of the diametrical bar. Sir George Shuckburgh, however, thinks that Ptolemy's astrolabe had two graduated circles placed at right angles. The ages of ignorance which succeeded Ptolemy produced no improvement on the astrolabe for more than fourteen centuries, and it is not easy to fix the exact date of the next succeeding instruments that owed their existence to the revival of letters. The most obvious, and therefore probably the first, improvement in the astrolabe, was an enlargement of its radius, for the purpose of making the divisions to be on a larger scale than the portable instrument at first had; this enlargement of the radius, of course, led to a reduction of the circle to a quadrant, which would naturally be supposed to be sufficiently extensive in its use, particularly for the purpose of taking altitudes, as they never exceed 90°. It does not appear, however, certain, when or by whom the plumb-line was introduced in the quadrant.

The introduction of the Indian, or Arabic numerals through Spain into England, must have contributed to a facility in reading the graduated divisions of a circular, or quadrantal instrument. According to Dr. Wallis, the first figures of this shape, which were noticed in England, were on a chimney-piece at Helmdon in Northamptonshire, in conjunction with the Roman characters, thus, M° 133, meaning 1133, which numerals fix their own date. Another step, towards the improvement of instruments of observation, was the introduction of optical glasses, and of optical instruments, which were made by the famous Franciscan friar, Roger Bacon, who was born in 1214. He talks of making small things appear large, and of bringing distant things near him by his instruments, so that he must at least have made Microscopes, if not, as some suppose, Telescopes also. It will not be deemed foreign to our present purpose to notice here that Paul the Venetian (see Costard's history of Astronomy, p. 65.) introduced the use of the mariner's compass, borrowed, as it is said, from the Chinese, in the year 1260; though it was not till 1300 that John Goia, a Neapolitan, the reputed inventor, introduced its use in navigating the Mediterranean. We are not assured, indeed, that the directive power of the magnet had any circular or other graduated instrumental appendage, as its variation from the true pole was not discovered till Christopher Columbus, the illustrious adventurer of Genoa, made this discovery in his voyage to the West Indies, on the 3d of August, 1492. The magnet's attractive power, however, had been previously known to the ancient Greeks. The next maker of astronomical instruments that we find spoken of in history, was John Muller, who, being born at Mons Regius in France, in 1436, was therefore called Regiomontanus; this illustrious scholar and astronomer, after having learned the doctrine of the sphere at Leipsic and Vienna, set about learning the Greek language, on purpose that he might make an epitome of Ptolemy's Almagest, or Great Syntax, which was written in that language; in which labour he was assisted by Purbach; and when, during the war between Matthias king of Hungary and the Bohemians, he retired to Nurembergh, he met with Bernard Walther, and other men of a mechanical turn, who assisted him in constructing astronomical instruments. The first attempt was to make rules of tin for observing the altitudes of the sun, moon, and planets, but particularly of the sun; whether these rules were made in the form of a sector, or in the form of a sliding cross, we are not informed. The second instrument made by Regiomontanus and his assistants was a rectangular, or astronomical radius, for measuring the angular distances of the planets; the third, by the same mechanician, was an astrolabe, either armillary, like that of Hipparchus, or planispheric, like Ptolemy's; and lastly, some minor instruments were constructed by him, such as the *torquet*, the *meteoroscope* of Ptolemy, and others of mere curiosity. This author established a printing-office at Nurembergh, and as he was the inventor of decimal arithmetic, we must suppose that his method of graduating his instruments, whatever it was, was adapted for decimal calculations.

A posthumous treatise by Regiomontanus on the subject of astronomical instruments is preserved in the British Museum, which is, perhaps, the only copy in the kingdom; its title is, "Scripta clarissimi Mathematici M. Joannis Regiomontani de Torqueto, Astrolabio armillari, Regulâ magnâ Ptolemaicâ, Baculoque Astronomico," &c. This treatise, which is in folio, was printed at Nurembergh in 1544. The torquet, which was a kind of portable equatorial,

rial, is also described in Bailly's "Astronomie Moderne," tome i. p. 687, and before either of the others by Apian in a scarce folio book, which has for its title "Introductio Geographica Petri Apiani in doctissimas Verneri Annotationes, &c. cui recens jam Operâ P. Apiani accessit Torcuetum Instrumentum pulcherrimum sane et utilissimum. Ingolstadii anno 1533."

Regiomontanus's description of Ptolemy's armillary astrolabe may be seen in Weidler's "Historia Astronomiæ," 4to. 1741.

About two centuries and a half after Regiomontanus, we find the celebrated Copernicus still using an astrolabe, his knowledge of which first gave him a taste for the study of astronomy, and consequently was the primary incident to which we are indebted for the introduction of our Copernican system, in which the systems of Philolaus and Hicetas are united. This celebrated astronomer of Thorn, in Prussia, wishing for tables preferable to those previously made by Ptolemy and Alphonsus, had a quadrant erected and fixed in the meridian line above the plane of the horizon about the year 1507, from which we may date the origin of regular observatories. This quadrant, of which we know not what were the exact dimensions, took altitudes of the sun by means of a cylindrical gnomon, or pin stuck in the central hole, the shadow of which, falling on the limb of the instrument, measured the greatest and least meridian altitudes of this luminary at the two solstices, and thereby ascertained the distance between the tropics and the height of the pole with considerable accuracy. But the instrument with which the altitudes of the heavenly bodies in general were taken by Copernicus, was a parallactical instrument made of fir, the limb of which, we are told, was subdivided into 1414 equal parts, just included in the quadrantal arc, that was contained between two legs of each four cubits long, which legs were respectively divided into 1000 parts, similar in magnitude to the subdivisions of the arc, according to Benj. Martin's account, in his "Biographia Philosophica;" but if the subdivisions were of similar dimensions on the arc and legs of the instrument, as is said, there must have been 7854 on the former, with 1000 on the latter, to form an exact quadrantal arc. The angle subtended by each space in the 1414 subdivisions of the limb must have been $\frac{90^\circ}{1414} = 3' \, 49''.137$, &c. which quantity might induce one to suppose, that the circle had not been hitherto divided into exact degrees and minutes on an astronomical instrument.

Tycho Brahe, who was born about 73 years after Copernicus, and who is well known as the inventor of the Tychonic, a kind of Ptolemai-copernic system of the planetary motions, had a more expensive collection of astronomical instruments than any one who preceded him. His observatory in the isle of Huen in the Sound, founded by Frederic II. of Denmark, was called "Uranibourg" (heavenly habitation), and had the first stone laid on the 8th of August, 1576. In his "Astronomiæ Instauratæ Mechanica," this author has described four instruments by the names of *armillæ, zodiacales,* and *equatoriæ,* varying from $4\frac{1}{2}$ to 10 feet in diameter, which were divided into degrees and minutes, and some of them even to 15 and 10 seconds. The towers in which these instruments were placed, had moveable roofs; and, what is worthy of remark, the axis of the ten-feet instrument was tapering and hollow, in order to have strength without increased weight, which construction our modern instrument-makers have adopted. The graduations of his instruments were into equal spaces of 10' each, and the intermediate minutes were ascertained by triangular diagonals formed of straight lines of ten equidistant dotted spaces, instead of parallel continued lines.

As Tycho Brahe cultivated also chemistry and metallurgy occasionally, it is very probable that his instruments were of better metal than the instruments of Copernicus, particularly when we take into consideration the circumstance of his having devoted nearly his whole life to astronomy, and pursuits subservient to this noble science, and also that he had several pupils or assistants learning to make celestial observations in Uranibourg; indeed, it is said in the original account, that the *constans axis* was made *e chalybe.*

About the beginning of the 16th century, when nautical astronomy had begun to be cultivated, a spirit for making discoveries, beyond what Columbus had made, spread itself over the different kingdoms of Europe; among these adventurers we find the names of Americus Vespucius, John and Sebastian Cabot, John Ponce de Leon, Cortez, Saavedra Guznam, Mendoza, Solo, Gonsalvo, Pizarro, &c. on the continent; and in England, sir Martin Frobisher, sir Francis Drake, Mr. John Davis, &c.; the last of whom we shall shortly have occasion to mention again. During the sixteenth century, quadrants, sectors, fore-staffs, and back-staffs, began to be made of various dimensions, and on various constructions, both for astronomical and nautical purposes, but when, or by whom, the plumb-line was first made a part of the astronomical quadrant, is a matter not easily ascertained at this distance of time: the graduations at first were pointed out by contact of a fiducial edge of the index, or were cut by a fine thread used as the line of the plumb, as seen in *Plate* I. *fig.* 4.; but this mode of reading an observation left much to conjecture, however small the subdivisions might be on the limb of the instrument. The first important improvement in the method of reading an observed angle, was that of Peter Nonius, or Nunez, a native of Portugal, born in 1497, which he described in his "Treatise on the Twilight," published in 1542. The contrivance was this; 45 concentric circles were described on a broad limb of the quadrant, and divided into spaces differing from one another by unity only in regular succession, beginning with 90, and ending with 46; so that the edge of the plumb-line, when resting on any particular point on the limb of the instrument, was certain to be contiguous to some one dividing mark in one of the 45 circles; which was an ingenious thought, but more plausible in theory than useful in practice; for the dividing of 45 circles into equal spaces of different numbers, out of which nine are prime numbers, was a laborious task to be performed with the requisite accuracy; and again, when the observation was read off, an arithmetical operation was necessary to reduce the observation to degrees, or parts of the largest circle; which operation was necessarily proportioned differently for each separate circle. But perfection is not usually attained at the first attempt in the construction of any new instrument, or new method of performing instrumental operations; the concentric circles of Nonius led the mechanician to the diagonal scale, which was formed successively by curved and straight lines. In the year 1573, the "Scalæ Mathematicæ" of Thomas Digges, esq. was published in London, in which is contained the method of making diagonal scales: the transition from Nonius's scale to the diagonal scale, with equidistant parallel curves, was easy; and it is said, was first effected by an ingenious workman of the name of Richard Chanseler. The diagonal scale, however, of either the curvilinear or rectilinear kind, was not well calculated for affording a very accurate reading of any observation, by reason of the difficulty of ascertaining the exact intersecting point of the scale, which a thread or edge of the index exactly covered, where the slope of the

diagonal

diagonal line did not deviate much from a radial line. Jacobus Curtis had a method of making scales for astronomical instruments, which was published by Clavius in 1586, at Rome. This method, like that of Nonius, consisted of concentric arcs, each differing in size by 1′ from the next contiguous: there were 39 of these concentric arcs, each divided by bisection into 128 equal parts, beginning with an arc of 90°, and ending with one of 128°. But, like Nonius's, this scale required an arithmetical reduction to degrees, though it had the advantage of being free from prime numbers. In or about the year 1590, captain John Davis, whom we have already named, contrived an instrument for taking altitudes, which consisted of two concentric contiguous arcs, one larger than the other, and three vanes; (see *Plate* I. *fig.* 2.). One vane was placed at the centre, and was called the horizon vane; another to slide on the arc of 60° of the small radius, and to receive the rays of the sun, which was therefore called the shade vane; and the third was made to slide on the arc of 30° of the long radius, for the eye to look through towards the horizon vane, and was thence called the sight vane. In using this instrument, the back was turned towards the sun; which circumstance gave the name of back staff also to the instrument, which far exceeded any nautical instrument that had preceded, both in accuracy and convenience. (See the article QUADRANT).

About the same time that Davis's quadrant was brought into use, we find another very similar instrument, called "Elton's Quadrant," made use of both at sea and on shore. This differs from the former principally, as it has its index levelled by a spirit level, which renders it useful where there is no good horizon to be seen. Its description may be seen in No. 423. of the "Philosophical Transactions," and in "Bion's Book," p. 274. See QUADRANT, and *Plate* I. *fig.* 8.

It is not quite certain at what exact period the instrument called the *fore-staff* or *cross staff*, (*Plate* I. *fig.* 3.), was used first in nautical astronomy, but as Bion calls the back-staff an English instrument, we may conclude it was contrived on the continent; the divisions are laid down on a long arm in the form of a tangent line, and three cross pieces of unequal lengths slide on this arm separately to the distance that allows the eye, placed at the extreme end of the arm, to see the horizon below and the heavenly object above the cross-piece used; the smallest sliding cross-piece will measure as far as 30°, the next in size 60°, and the largest 90°, when placed at the interior end of the divided scale. This instrument, when well made, was very convenient at sea, but was incapable of having the diagonal scale applied, as the divisions were unequal: it was capable of measuring angular distances as well as altitudes.

Another instrument used in navigation and astronomy was the nocturnal, (*Plate* I. *fig.* 6.) which consisted of a handle, an index with sights, and two circular plates revolving on the same central pin, so divided as to be capable of adjustment for the right ascension of some given circumpolar star, as compared with the pole-star on any day of the year; its use was, to find the hour, and to take the altitude and depression of the pole-star at any place, and consequently to determine thereby the latitude. Its exact date is not, perhaps, well known.

About the end of the 16th century, Edward Wright, of Caius college, Cambridge, in whose time the fore-staff or cross-staff was used, introduced the sea-rings for determining the variation of the magnetic needle, which instrument, no doubt, was the origin of our azimuth compass, as it is said that the altitude of the sun and hour of the day could be determined by it. The same ingenious mathematician made a six-foot astronomical quadrant better than any that had been made in England, and rectified with it the declinations of the stars, as given in the former catalogues; which labour was performed in the years 1594, 95, 96, and 97; he also made a sea-quadrant that would take altitudes by either a forward or backward observation, and that would determine the latitude by the observed height of the pole-star, even out of the meridian, which must have been an ingenious contrivance.

After the invention of logarithms by baron Napier in 1614, calculations began to be abridged, and numerical proportions began to be performed by logarithmic scales. The first of these was by professor Gunter, of Oxford, who, in the year 1618, contrived also a quadrant, bearing his name, which having a stereographic projection of the sphere on its plane considered as the equinoctial, ascertained the hour as well as azimuth, altitude, declination, and place of the sun, by an observation without subsequent calculation, and these with some degree of accuracy.

Contemporary with professor Gunter, was the celebrated Galileo of Italy, who, having heard of a certain glass in Holland, that would shew objects at a distance distinctly, set about contriving the dioptric telescope, in which he succeeded; and we find Christopher Scheiner using one moveable on a polar axis in the year 1620 *(vide Rosa Ursina)*; this discovery led ultimately to considerable improvements in astronomical instruments, though the unequal refrangibility of the different coloured rays of light prevented its being constructed with much power, and at the same time of a convenient length, for many years afterwards.

The invention of the micrometer, or mechanism in the eye-piece of a telescope, for measuring very minute angles, soon followed the invention of the telescope itself, and contributed greatly to the accuracy of observations, taken by the help of that instrument. It has been generally supposed that Monf. Auzout, a Frenchman, was the author of this invention, in the year 1666, but according to Costard, an English gentleman of the name of Gascoigne was the real inventor, as appears by a letter written by himself, in 1641, which is still extant in the library of the Earl of Macclesfield. Gascoigne was slain near York in the civil wars in the year 1644.

In 1658, John Collins, an eminent mathematician of the county of Oxford, published a pamphlet, entitled "The Sector of a Quadrant," in which are described four different quadrantal instruments, but that which is called Collins's or Sutton's quadrant, contains a stereographic projection of one quarter of the sphere, between the tropics on the plane of the ecliptic, agreeably to the latitude of London, the eye being supposed to be placed in its north pole: the use of this quadrant is very similar to that of Gunter, from which the idea was no doubt borrowed.

Another very important improvement in astronomical and nautical instruments, was the divided scale at the end of the index, contrived by Peter Vernier, a gentleman of Franche Comté, and described in a small tract, called "La construction, l'usage, & les proprietes du Quadrant Noveau de Mathematique, &c." which was published at Brussels in 1631. As this contrivance will be particularly described in its proper place, it may suffice to say here, that when the limb of the instrument is very equally divided by nice strokes into halves, thirds, or fourths of a degree, an arc containing a given number of those divisions is laid on a circle described on the end of the index contiguous to the divided limb, which equal arc is divided into the same number of spaces, as its like arc on the limb, with the difference of *one*; so that

that if the limb contains 19 or 21 thirds, the index or rather that portion of it which subtends precisely the same sectoral arc, must contain 20 spaces, then when No. 0 on the index is put to any line on the limb, so as exactly to coincide, No. 1 of the former will not exactly coincide with the next succeeding line of the latter by $\frac{1}{20}$ of a space, and No. 2 on the index will be $\frac{2}{20}$ from an exact coincidence, and so on till the end of the scale on the index, where there will be a second coincidence; but whenever No. 1 does not coincide, there is only one coincidence, which may fall at any number of lines from 1 to 20 on the Vernier; but we have said the limb is divided into thirds of a degree, when the scale has 20 divisions, therefore $\frac{1}{20}$ of $\frac{1}{3} = \frac{1}{60}$ of a degree $= 1'$. When the divisions of the limb are halves of degrees, the scale has 30 divisions covering exactly 29 or 31 on the limb; and when they are quarters, 15 on the scale must just cover 14 or 16 on the limb. This scale is called a *Vernier* from the inventor's name, but is frequently, though very improperly, even by instrument-makers themselves, called a *Nonius*, from which it is quite a different thing: by means of a Vernier a very small circle may be graduated so as to shew *minutes* of altitude or of angular distance.

According to Joannes Baptista Morinus, Joannes Ferrerius, an ingenious workman, contrived a kind of circular diagonals, which, if continued, would pass from the limb to the centre of an instrument, but to avoid trouble, he laid 60 of these on the index, which intersected straight lines drawn from the centre in such a way that these straight degree lines marked the minutes by their intersections with the curves of the index. The account was published in 1634, but this method was not found so good as that of Vernier, and therefore was discontinued.

Notwithstanding telescopes, as we have said, were necessarily very long, to obtain much power, in order to be free from a discolouration in the eye-piece, yet we learn that so early as the time of Dr. Robert Hooke, certainly one of the greatest mechanicians of his own, or perhaps of any other age, telescopic sights were applied to the astronomical quadrant, as his well known dispute with Hevelius of Dantzic will testify. Hevelius's Cometographia, which induced the dispute, was published in 1668, which will fix the date pretty nearly of the telescopic sights. It is somewhat extraordinary, that the dispute alluded to terminated with the public opinion in favour of plain sights, in preference to telescopic ones, as to the accuracy of observations made respectively with each; though Dr. Hooke contended that Hevelius could not measure a smaller space in the heavens than *a minute* by plain sights, whereas he could measure to the accuracy of *a second*, with a radius of a span long. This degree of accuracy in Dr. Hooke's observations, if really effected, one might suppose, left his successors little more to do, but to copy his method of constructing instruments, and of observing by them; and our reflection upon his assertion would have led us to infer that he must have measured his *span* with very long fingers, had we not previously known that his person was of very short stature: his unwillingness to allow a competitor in mechanical inventions may in some measure account for the greatness of his pretensions. Doctor Hooke had moreover a zenith sector with a telescope of 36 feet focal length, fitted up with plumb lines in his apartments at Gresham college, which had a micrometer in its eye-piece, and we suspect that this was the instrument with which he measured to the accuracy of *seconds*.

We have now arrived at a period in the history of astronomical instruments which is truly important. The introduction of pendulum clocks, of the vernier, and of the telescope, with a micrometrical eye-piece, together with a fine plumb-line, had become valuable additions to the simple sector or quadrant; and in the year 1660, Huygens brought into England the art of grinding and polishing glasses suitable for telescopes: in the same year the Royal Society of London was founded by Charles II.; in 1670 the Royal Observatory at Paris was begun, to which Cassini was appointed in the following year; and on the 10th of August of the year 1675 the first stone was laid of the Royal Observatory at Greenwich, to which fortunately the celebrated Flamstead or Flamsteed was appointed the following year. These institutions of course produced a demand for good instruments, and, what is somewhat remarkable, the first man of eminence in this way, Geo. Graham, was born in a village in Cumberland, (which county has since given birth to many of the most eminent mechanicians), in 1675, the very year in which the observatory itself was founded. The new astronomer royal observed, as might be expected, with instruments of a large radius nicely divided, and furnished with telescopic sights. One of those instruments was a large sector or sextant, constructed, as has been said, by a Mr. Abraham Sharp, the assistant to the astronomer royal, whose skill as a mathematician rendered him worthy of his situation, and we are told in Dr. R. Smith's Optics, that a quadrant, similar to those of Tycho Brahe and Hevelius, was fixed in the meridian by a solid wall, whence it was called a *mural arch*, and was, we understand, made by Flamsteed himself and his assistant.

Doctor Edward Halley, who had been fixed upon to go over to Dantzic in the year 1679, to settle the dispute between Doctor Hooke and Hevelius, which we have before mentioned, and who in the year 1713, succeeded Sir Hans Sloane as Secretary to the Royal Society, was appointed to the situation of astronomer royal, at the death of Flamsteed, in the year 1719, when he was nearly 65 years old, in which situation he continued 18 years. Doctor Smith says that Halley made use of a meridian telescope, and a pendulum clock for determining the right ascensions of the stars before the great mural arch by George Graham was made for the observatory; the telescope in question is particularly described (Smith's Optics, p. 321. and seq.) as having a transverse axis of an ell in length, and a tube of $5\frac{1}{2}$ feet, which had cross hairs in the eye-piece with proper adjustments, a frame with the Y supports, and a spirit level for levelling the axis; in short it was what is now denominated a transit instrument, and probably was the same which Evans mentions in his Tour as being still at Flamsteed house, with the telescope fixed near one end of the axis. Graham's great mural arch is also particularly described by the same author, which consists of iron bars firmly joined together, and a brass arc of 90°, divided by a beam compass, with a degree of accuracy that far exceeded any thing that had been before attempted. Besides the arc of 90°, there is another quadrantal arc divided into 96 equal parts, as a check on any inequality that might be supposed to exist in the graduated arc of 90°. The particulars of the construction of this instrument, of which the radius of one qudrantal arc was 96.85, and of the other 95.8 inches, together with the method of dividing the limb, and of making the centre work, &c. are treated of from page 332 to page 341 of Smith's Optics, in the latter part of which account it is said, that Sisson of the Strand made a similar mural arch for Colin Campbell, esq. to be used in Jamaica.

The micrometers at this time used, began to be differently constructed: Romer or Roëmer at Paris, who was contemporary with Flamsteed and Huygens, and who had a transit instrument in 1700, contrived a piece with ten squares, called a retia reticulum put in the body of a microscope, as we understand, where the focus of the eye-glass meets the magnified image, which squares were placed opposite the graduations of the divided limb of an instrument, and acted probably as a kind of Vernier. Huygens proposed parallel straight-edged brass plates to slide and to include the measured object between them; the distance of which plates was afterwards measured by a scale and compasses:—Cassini observed by four parallel hairs placed in the focus of the eye-piece, and made adjustable for collimation.—Before we part with Dr. Smith, whose book will long be admired, we beg leave to observe that he mistakes the name of the Vernier, which Graham's quadrant had, and mis-names it a Nonius, as various authors have done since, no doubt, on the strength of his authority. It was during the life of Dr. Halley that Mr. Roger Cotes contrived an equal altitude instrument to adjust the pendulum clock by, which sir Isaac Newton presented to Trinity college, Cambridge; this instrument consists of a telescope leaning on an inclined gibbet-piece, that revolves on an upright axis placed in pivot holes above and below, and kept perpendicular by a suspended fine plumb-line, which, revolving with the upright axis, detects its want of perpendicularity in any point of its revolution. This instrument, which does not seem to have come into general use, is likewise described by Dr. Smith (p. 327 to p. 331).

It was also during the presidency of Dr. Halley at Greenwich, that the first achromatic or colourless telescope was invented, though not generally used, nor even known by that name, till Mr. John Dollond afterwards took out a patent for the invention, and brought the execution of it to great perfection. So along ago as the year 1729, Chester More Hall esq. of More Hall, in Essex, considering the different humours of the eye, was led to infer, that they were so arranged as to correct the variable refrangibility of the different rays of light, which idea probably was suggested by sir Isaac Newton's experiments on optical glasses. He then conceived that if he could meet with transparent substances possessing the same peculiar properties as he supposed the humours of the eye to possess, he could make an object-glass that would unite all the colours in its focus. After several experiments with different kinds of glass, he succeeded, in the year 1733, in completing object-glasses of the desired construction, which bore an aperture of 2½ inches, with only a 20 inch tube; and we are informed that one of these original object-glasses is still in the possession of a clergyman of the name of Smith, who lives in Charlotte-street, Rathbone-place, which object-glass, on examination by several scientific gentlemen, has been found to possess the achromatic property; and in 1754, Mr. Ascough, optician on Ludgate-hill, was in possession of one of Mr. Hall's telescopes of the achromatic kind. Indeed, when it was allowed at the trial at Westminster Hall, respecting the patent for making achromatic telescopes, that Mr. Hall was the original inventor, lord Mansfield, who did not deny the proof of the fact, observed, that "it was not the person that locked up his invention in his scrutoire that ought to profit by a patent for such an invention, but he who brought it forth for the benefit of the public."

The same ideas respecting an object-glass had, it appears, occurred to the celebrated Euler and other foreigners, but no one is so clearly entitled to the honour of the invention as Mr. Hall, nor did any one succeed in practice so well as Dollond, who therefore was entitled to his portion of the honour of an improvement in optical instruments, which, together with the compound or achromatic eye-glass, has contributed very much to the nicety with which observations are made and read off by modern instruments of the different constructions.

Dr. Halley was succeeded by Dr. Bradley in the year 1741, for whom Graham made a sector of 10°, bearing a Vernier with a screw of adjustment, and a telescope with another Vernier separately moveable, (see *Plate* I. *fig.* 5.); the use of this instrument was to take the *difference* of the right ascension and declination of a planet or comet, and of a known star, and consequently the right ascension and declination of the wandering body itself, by a cheap and simple contrivance. The instrument turned on a long axis, and was so contrived, that both the bodies that were compared together, might be seen passing the micrometer of the telescope without altering the elevation more than 10°. Dr. Bradley, we find, was the inventor of the screw-micrometer, and also of a kind of triangular micrometer, adjustable by a circular motion given to it by a sectoral rack and endless screw, the use of which was to take declinations; but this second mechanism is not adopted in subsequent instruments. When the Royal Society made their annual visit to Dr. Bradley to inspect his instruments in 1748, he complained of wanting new ones; in consequence of which complaint, his majesty ordered 1000*l.* to be expended in furnishing a proper supply, which enabled the astronomer-royal to procure not only the sector we have just mentioned, but also a large mural arch of brass of eight feet radius made by Bird, which is now in use, and which is too well known to astronomers to need further notice till we come to the proper place for describing it particularly.

While these improvements were going on in the English instruments of observation, Peter Horrebow published a pamphlet, in 4to. called "Basis Astronomiæ, sive Astronomiæ Pars Mechanica," Hauniæ 1735, in which a *meridian circle* is described, to which was attached an optical tube with Romer's *reticulum* of ten squares for reading off the divisions on the limb, and which had been intended by the inventor for a quadrant. We find, notwithstanding this early notice of a circle, that La Caille made his catalogue of southern stars from observations made with a *sector* at the Cape of Good Hope between the years 1750 and 1754.

The English transit-instrument was by and bye made portable, and the improved modern manner of grinding the tube, that contains the spirits, on the interior surface, has rendered the bubble capable of indicating not only minutes of a degree by its run, but in many instances seconds; the manner also in which the cross and parallel hairs are enlightened by the reflection of light entering the end of the axis from a diagonal mirror placed in the body of the tube, renders the use very convenient at all elevations; and, lastly, the diagonal eye-piece for high altitudes, and a graduated circle with a spirit level at the end of the axis, to ascertain the elevations proper for given stars, together with the various other adjustments, leave little more to be expected, or even wished for, as an improvement of this instrument, notwithstanding the Society of Arts at the Adelphi have repeatedly advertised a reward, among their proposed annual premiums, for an *improvement* in the *portable transit-instrument.*

The invention of catoptric or reflecting telescopes may here also be mentioned among the improvements made in astronomical instruments. Mr. Short was probably the first who brought these to any degree of perfection, and his description of various circles united with a catoptric telescope, as described in the Philosophical Transactions of London in 1789, laid the foundation of the *equatorial instrument,* as afterwards improved by Ramsden, Nairne, and the Dollonds, about the year 1770 or soon after, (vide the Phil. Trans.

Tranf. 1771); fince which time the achromatic telefcope, being lighter, has had the preference, except for the purpofe of ftar-gazing, where the comparative brightnefs and magnitudes of the ftars are the principal objects of obfervation. Of this kind of inftruments Dr. Herfchel's far exceed in power any others that have been made.

With refpect to the comparative accuracy of the inftruments hitherto made for obfervatories, we beg leave to tranfcribe fir George Shuckburgh's words from his account of the equatorial inftrument, publifhed in the Philofophical Tranfactions of London in the year 1793, who fays "that from the time of Hipparchus and Ptolemy, before and at the commencement of the Chriftian æra, to the age of Walther and Copernicus, in the beginning of the 16th century, few obfervations can be depended on, to within lefs than 5, 8, or perhaps even 10 minutes; thofe of Tycho Brahe, indeed, that princely promoter of aftronomy, to within 1 minute. The errors of Hevelius's large fextant of fix feet radius, towards the middle of the laft (17th) century, might amount to 15 or 20 feconds; Flamftead's fextant, to 10 or 12 feconds; and laftly, thofe of Mr. Graham's mural quadrant of eight feet radius, with which Dr. Bradley made fo many obfervations from 1742, might amount to 7 or 8 feconds.

The *nautical* inftruments of obfervation hitherto made were, however, by no means well calculated for taking altitudes or angular diftances during the different motions of a fhip under way: the great difcovery that has proved moft permanently ufeful in a voyage, was that which pointed out the ufe of a *mirror* as attached to the limb of an inftrument. A metallic mirror was known to the ancient Greeks and Romans, and was made fometimes of filver, fometimes of a compofition of copper and tin ("ftanno & ære miftis," Plin. lib. xxxiii. cap. 9.) and fometimes of a polifhed opaque ftone, or of coloured glafs; and the knowledge of the reflecting property of glafs with a metal in contact with the back furface, if it was not known to the Sidonian mirror-makers mentioned by Pliny, when he fpeaks of glafs mirrors, was known to Alexander, the reputed author of the "Problemata;" for he exprefsly fays, "Διατι τα ὑελινα κα- [illegible] δ'αυτου η φυσις διαυγης, και τῃ ὑελῳ αναμιγνυμενη, λαμπρα ουτη, πλεον διαυγαζεται," &c. which may be tranflated thus: "Why do the glafs-mirrors fhine fo much? Becaufe they anoint them with tin, the nature of which partakes of a pellucid property, and being joined to, or mixed with, the glafs that is tranfparent, becomes more fhining," &c. We do not introduce this quotation for the fake of its reafoning, but to fhew that glafs mirrors coated with tin, were known when Alexander wrote the "Problemata," but whether it was Alexander Aphrodifias of the third century, or Alexander Trallianus of the fixth century according to others, we pretend not to determine; and that the art was preferved is clear from the writings of John Peckham, or Peccam, an Englifh Francifcan monk, who wrote his "Johannis Pifani Perfpectiva communis" in 1279, in which are mentioned various kinds of mirrors, and among others, fteel mirrors and mirrors of glafs, covered on the back with lead, which lead Vincentius Bellovacenfis fays (Specul. Natur. ii. 78. p. 129.) was poured over the glafs-plate while hot; fo that our amalgam of tin-foil and mercury is an improvement on the ancient method of making the mirror. The firft idea of ufing a mirror in a nautical inftrument, it fhould feem from Dr. Sprat's "Hiftory of the Royal Society," originated with Dr. Hooke, and, according to the doctor's pofthumous works, an inftrument of this kind was actually made for obfervations at fea, in which the eye faw at once two objects fituated at a diftance from each other, but brought together by reflection of one of them; in this inftrument, however, there was but one reflection, and it was not till fir Ifaac Newton took up the fubject, that an inftrument, fuch as is reprefented in *Plate* I. *fig.* 7, with two reflections was contrived, which conftruction this prince of mathematicians communicated to his friend Dr. Halley, in a paper that was found after the doctor's death by Mr. Jones, and given to the Royal Society of London, in whofe Philofophical Tranfactions it was publifhed in the year 1742. In the mean time John Hadley efquire, a friend of fir Ifaac Newton, had fomehow become acquainted with the fame principle of a double reflection, as had alfo Mr. Godfrey of Pennfylvania, both of which latter gentlemen have been honoured with the reputation of being the inventors of the reflecting octant, which bears the name of Hadley's quadrant, becaufe, though actually only the eighth part of a circle, it meafures 90° by reafon of the reflected ray having double the velocity of the incident ray, as coming from the obferved object. The peculiar advantage of Hadley's octant over all the preceding inftruments ufed at fea, confifts in its being capable of ufe during the toffing of a fhip under way; and the appendages of telefcopic fights, dark-glaffes to take off the glare of the fun, and a Vernier's fcale, have rendered it fo complete, that, when well made and perfectly divided, no better inftrument for taking altitudes at fea can reafonably be defired, particularly when a tangent-fcrew of adjuftment for quick and flow motions and a reading lens are fuperadded.

But excellent as Hadley's quadrant is for taking altitudes when divided in the beft manner, it is not competent to one very effential purpofe of nautical aftronomy: it will not meafure an angle of any kind of more than 90°. When the tables of the folar and lunar motions were prefented to the lords of the admiralty in the year 1755 by Tobias Mayer, of Gottingen, and when a reward of 3000*l.* was afterwards given by the Britifh parliament, to the celebrated author, the method of finding the longitude of a fhip or place by meafuring the moon's diftance from the fun or from a ftar, at firft fuggefted by Gemma Frifius, was now propofed to be put in practice; but this method required that angular diftances fhould be accurately meafured; we fay *accurately*, becaufe an error of *one minute* of fpace in taking an obfervation of the moon's diftance, which would not materially affect the determination of a latitude from an obferved altitude, will, at a mean rate of the moon's motion, produce an error of about 25′ in longitude, as afcertained by the lunar method, the moon and ftar being fuppofed to be both in or near the equator. Mayer, whofe anxiety to promote the lunar method muft have been equal to that of any other man, not excepting doctor Mafkelyne himfelf, who undertook the calculations of the Nautical Almanac for this purpofe, was well aware of the celebrity of the Englifh inftrument-makers, fuch as Bird, Ramfden, Sifion, Troughton, &c. and therefore contrived a new inftrument, which was made from his directions by Bird, to take angles of any magnitude within 160°, and with fuperior accuracy; this author very properly judged that there might be three principal caufes of inaccuracy in the ordinary octant, of whatever radius, notwithftanding they were divided by very fuperior workmen; one of which errors might be an inequality among the fubdivifions; a fecond, the want of exactitude in the total magnitude of the divided arc; and the third, an error in the meafure arifing out of the eccentricity of the point round which the index turned, as it regarded the graduated fector of the limb. Thefe three fources of error were to be guarded againft, but particularly the firft, in the conftruction of a new inftrument; our author's thor's idea was a happy one; he availed himſelf of all the ingenious contrivances that Hadley's octant poſſeſſed, extended its limb to a circle, agreeably to the original conſtruction of the aſtrolabe, and meaſured his angle many times over on different portions of the circumference; after which he divided the whole amount by the number of obſervations for the mean quantity of the obſerved angle, which method included the corrections for all the ſources of error to which he could conceive the octant liable. As we ſhall give a perſpective drawing of the original inſtrument made by Bird, and uſed by admiral Campbell, we ſhall defer our further remarks on it till we come to our particular deſcription.

Admiral Campbell, however, having found the repetition of his obſervations with a large and heavy inſtrument troubleſome, diſpenſed with the original principle, and having found, as he ſuppoſed, one-third part of the circle better divided than either of the other two, made uſe of that only for ſingle obſervations, and reported ſo favourably of his method of uſing the third part of a circle only, that ſextants on Hadley's principle came immediately into uſe inſtead of reflecting circles, from this peculiar circumſtance, which we here mention, becauſe it has been generally aſſerted, upon ſuppoſition only, that circles did not precede, but followed reflecting ſextants; even Dr. Mackay has fallen into this error, when he ſays that the circular inſtrument "was propoſed, with a view to correct the errors to which a ſextant is liable." (Theory and Practice of finding the Longitude, vol. i. p. 65.)

Chevalier de Borda, of Paris, ſoon noticed, among others, that the two indices of profeſſor Mayer's circle, which carried, one the central mirror, and the other the teleſcope and horizon-glaſs, required to be both moved in ſucceſſion at each obſervation, ſo as to render two operations indiſpenſable for aſcertaining one ſimple meaſure of an angle; after ſome conſideration, he hit upon an improvement, by means of which the double of any angle could be as readily meaſured as Mayer's ſingle angle, while yet the principle of the repetition with one reading off at laſt was retained, and the mean angle was aſcertained by dividing the whole amount by double the number of obſervations, ſuppoſing them to have been all double angles. This invention ſhortened the proceſs of repeating the obſervations, and will be alſo deſcribed at full length hereafter.

But Mayer's and Borda's reflecting and repeating circles were both ſubject to great inconvenience in uſe, partly from the tedioufneſs of aſcertaining the exact time, which the mean of all the obſervations was to be put down for, and partly from the unſteadineſs and other objections, occaſioned by two indices ſeparately moveable, and the frequent eſtimations by the eye of the coincidence of the direct and reflected objects at each obſervation; their principal property being to diminiſh the errors of diviſion of a bad inſtrument, and to render it capable of uſe, when it could not be depended on for taking a ſimple obſervation. It has fallen to the lot of Mr. Ed. Troughton, whoſe nautical and aſtronomical inſtruments are known, and highly valued all over the world on account of their accuracy, to make a very eſſential improvement on the foregoing reflecting circles, in 1796, without being ſubject to theſe and ſimilar objections, which will hereafter be mentioned; he has retained the principle of meaſuring an angle to the right and left of Zero, when the inſtrument is properly ſet, and inſtead of repeating the obſervation round the different portions of the limb, to do away the errors of eccentricity and of imperfect diviſions, he uſes three Verniers at 120° diſtance from each other, which ſeparately meaſure each a double angle; ſo that at one obſervation taken backward and forward, the average of ſix different ſextants is obtained without the leaſt trouble or liability to miſtake the inſtant of obſervation; for fixing one of the Verniers fixes them all till their meaſures are ſucceſſively read off, which may be an hour, or even many hours after the inſtant of the obſervation has been noted. The conſtruction and uſe of this very perfect inſtrument will be deſcribed more particularly in its place, which will be the more intereſting, as its powers and peculiarities have never been heretofore laid before the public in a regular deſcription.

About the year 1800, Joſeph de Mendoza Rios Eſq. F.R.S. the author of the collection of Nautical Tables, which we had occaſion to mention in reſpectful terms under our article CHRONOMETER, and who has for ſome time ſhewn a great deſire to promote the intereſts of navigation, (being himſelf a captain in the ſervice), invented an ingenious method of transferring the motions of both the indices of Borda's reflecting circle, into one reading by what he terms a *flying nonius*, or more properly ſpeaking, a *flying Vernier*, by means of which the velocity of repeating an angle with Borda's circle is doubled. This inſtrument is deſcribed in the Philoſophical Tranſactions of London for the year 1801. The conſtruction of Borda's circle, however, being unfit to receive the propoſed improvement, the thing was found not to anſwer in practice, but ſhews well enough the *principle*, which was at that time the chief deſign of the author. Subſequently to the above period, an union of the conceived principle with Troughton's conſtruction was found to anſwer a much better purpoſe; for by this union, not only is the repeating or multiplying property reſumed, but the alternate motion of the index is transformed into a continued motion, ſo that the whole amount of the croſſed obſervations is read off at laſt by two ſeparate Verniers. This being a great improvement of Mendoza's original reflecting circle, and not having been any where publiſhed, ſhall be deſcribed in its turn after Troughton's, to which it is a relative.

While theſe improvements have been going on in the fabrication of nautical inſtruments, correſponding improvements have alſo been made in inſtruments appropriated to obſervatories; the original circle, which had long ago been commuted for the aſtronomical quadrant, ſextant, or ſector, was again brought into uſe, and for the ſame reaſons that the nautical circle was revived after the aſtrolabe had been laid aſide. As it is our intention particularly to deſcribe in ſeparate ſections the principal circular inſtruments uſed in practical aſtronomy, as well as the principal nautical circles, it would be ſuperfluous to give here more than a brief hiſtorical notice of each.

We may go back to the year 1768, when Le Duc de Chaulnes publiſhed a work, which we ſuppoſe may have ſuggeſted to the Engliſh inſtrument-makers, ſome notion of the uſe of a microſcope and micrometer uſed in conjunction to read off the ſubdiviſions of the circular limb of a large inſtrument; the work is entitled, "Deſcription d'un Microſcope et de differens Micrometres deſtinés à meſurer des parties circulaires ou droites avec la plus grande preciſion, 1768, à Paris." We have not the work before us, and therefore are unable to ſtate, in what particulars the propoſed apparatus differed from that previouſly propoſed by Romer by the name of a *reticulum* or *reticule*. When the late Jeſſe Ramſden, whoſe eminence as an inſtrument-maker will never be forgotten, was applied to, about the year 1785, to make an inſtrument for meaſuring horizontal angles with more preciſion than the ordinary theodolite is capable of, he

adopted

adopted the plan of reading off by microſcopes the ſubdiviſions of his large circular inſtrument, which was uſed in the trigonometrical ſurvey, made for the purpoſe of meaſuring the linear diſtance from the two obſervatories of Greenwich and Paris, under the direction of general Roy.

Profeſſor Vince has deſcribed this inſtrument in his practical aſtronomy, (p. 170.) The line on the French ſide was meaſured by the help of a repeating inſtrument without reflection, contrived by the Chevalier de Borda, which we propoſe to deſcribe more fully preſently.

But Ramſden was not ſatisfied with applying the new method of reading off by microſcopes, which he could do repeatedly within the accuracy of *one ſecond* of ſpace, to horizontal angles only, but in a large circular inſtrument, which he finiſhed for Piazzi of Palermo in 1789, to be placed in his obſervatory, the ſame mode of meaſuring this very minute portion of a degree, was adopted with complete ſucceſs in a vertical circle, as will be ſeen in our ſubjoined account of this expenſive inſtrument.

Nor was Mr. Ramſden the only Engliſh maker of aſtronomical inſtruments, who has conſtructed aſtronomical *circles* or circular inſtruments, on the plan propoſed by the Duc de Chaulnes; Mr. Ed. Troughton, and Mr. Wm. Cary have ſucceded in ſimilar attempts, and we can venture to affirm, that their inſtruments have not been equalled in excellence, by thoſe of any foreign maker whatever; of the veracity of which aſſertion it will be conſidered as a ſufficient proof, that all the beſt obſervatories on the continent are furniſhed with Engliſh inſtruments, and chiefly if not entirely by thoſe three makers, including Berge, Mr. Ramſden's ſucceſſor, under his name.

Thus have we given ſuch a ſketch of the riſe and progreſs of aſtronomical and nautical inſtruments, particularly circles, as will enable the reader, we preſume, to appreciate the value of each improvement, and to underſtand the uſes and originality of the different parts of the inſtruments of which we have thought it right to ſubjoin appropriate deſcriptions.

The German reflecting and repeating Circle, *by Tobias Mayer of Gottingen.*

After having peruſed the Latin deſcription of the circle of Tobias Mayer, as publiſhed by him in his "Tabulæ Motuum Solis et Lunæ," Londini, 1770, and compared it with the inſtrument itſelf, (No. 9.) as originally made by Bird for the uſe of admiral Campbell, we found that the Author's plate and deſcription are defective, inaſmuch as ſome of the appendages found neceſſary by the maker are omitted; we therefore cauſed an original drawing to be taken in perſpective, which we now come to deſcribe, and to which we have put Mayer's original large letters of reference, and ſome of the ſmall ones as far as they would go; we propoſe alſo to deſcribe the parts of the inſtrument, and their uſes nearly in the ſame order in which their author has deſcribed them, that his ideas may be the better preſerved. *Fig.* 1. *of Plate* II. of *Aſtronomical inſtruments*, is a repreſentation of the inſtrument in an entire ſtate; in conſiſts principally of three parts with their appendages; namely, the graduated circle A, the radial bar C, and the teleſcope on the radial bar G; the inventor propoſed the circle to be of 8 inches radius, which we find is juſt 8.7 from the divided circle, and 9 to the circumference; this meaſure of 8 inches was fixed upon, becauſe it was ſuppoſed by Mayer that a larger would make the inſtrument too heavy, and that a ſmaller could not be divided accurately enough to guard againſt an error, in the meaſurement of a lunar diſtance of 3′, correſponding to about 1° 14′½ of determined longitude, notwithſtanding the addition of a vernier; a ſuppoſition which, our pocket box ſextants ſhew, was widely erroneous; as the inſtrument was intended to meaſure angles by reflection, like Hadley's octant, uſually called quadrant, it was at firſt propoſed that the whole limb of the circle ſhould be graduated into 720 parts inſtead of 360°, becauſe the reflecting inſtruments meaſure a whole degree by *halves* marked on their limbs, and figured as *wholes*, but Bird thought proper to put on only 360°, each of which is ſubdivided into *three*, and reads with a vernier of 20 ſpaces, covering 19 on the limb, ſo that the quantity read off requires to be doubled to bring it into exact degrees and minutes of reflected meaſurement. The centre work is ſimilar to that of Hadley's quadrant, except that the radial bars C and G, to each of which a vernier is put at *h* and *k* reſpectively, move ſeparately. The bar G grows wide enough before it comes to *g* to admit a large circular hole, the centre of which is properly its centre of motion; which is alſo the caſe with the bar C: the bar G prolonged beyond the centre a little way carries a ſquare piece of ground and poliſhed glaſs *b*, of which the lower half is ſilvered and kept faſt in a little braſs frame, adjuſtable for perpendicularity by ſcrews below; on the ſame bar is alſo carried the teleſcope B, in two pair of jointed little ſupports *f* and *f* ſcrewed to the bar G, ſo moveable like an ordinary parallel ruler, in a longitudinal direction, that when the ſaid jointed ſupports are perpendicular to the plane of the bar G, no part of the glaſs *b* can be ſeen, but the part which is not ſilvered; but when the teleſcope is puſhed nearer to or drawn further from the ſaid glaſs, the line of collimation of the teleſcope approaches the bar G, and its field of view takes in alſo the ſilvered portion of the ſmall-glaſs; and thus any portion or nearly the whole of this glaſs may be readily taken in by the eye at the end of the teleſcope. This contrivance was not in the original ſketch, but was no doubt added by the maker, and has another convenience beſides its uſe in the adjuſtment juſt mentioned, which is, that by the teleſcope's approaching the bar G when puſhed forwards, a more ſhallow box will ſuffice for packing the inſtrument than muſt neceſſarily have been uſed if no ſuch motion of the ſupports *f* and *f* had been there. In the focus of the eye-piece there are three fine wires, two parallel at ſome diſtance on each ſide of the centre of the field of view, and one at right angles to the other two cutting the exact centre; the tube is 10 inches long, and the magnifying power juſt *four*, with a field of view of 2° 15′; the object glaſs is of the achromatic kind, and the eye-glaſs being a ſingle lens inverts the object, which is of no conſequence in celeſtial obſervations.

The radial bar C which carries the index *k* has the large central mirror attached to it, and has adjuſtable ſcrews for perpendicularity like thoſe of glaſs *b*, and is in every reſpect like the index bar of a Hadley's quadrant; it is placed above the plane of the bar G, and, as has been ſaid, moves ſeparately from the teleſcope. The piece *d* near K is a holding piece of metal claſping the limb in ſuch a way, that, when its fixing ſcrew, the head of which is a milled nut at *d*, is faſt, it fixes the bar C immoveably, by means of the tangent ſcrew *i i* which is tapped into a little ball at the outer end of this bar. The tangent ſcrew has two milled nuts as heads at its oppoſite end, by either of which it may be turned, as convenience may require, and, when the piece *d* is ſcrewed faſt to the limb, the tangent-ſcrew is moreover uſed to adjuſt the bar C and its mirror, till the real object, and object by reflection exactly coincide: at the end of the bar G, under the eye piece of the teleſcope, is a ſimilar tangent ſcrew and fixing apparatus, the whole of which cannot be ſeen in the figure; but when the reader is told

told that the milled nut at *e*, is exactly similar to the one which has been described at *d*, the portion out of sight will easily be apprehended; there is however a second fixing screw below, as well as the one *e* above, which may sometimes be more convenient to use, or which for the sake of greater security may be used along with the other. *Fig.* 2. is a dark glass in a frame which may be placed, when the sun is one of the observed objects, parallel and near to the mirror *c* by its cross *n*, the edges of which are sloped, sliding into a corresponding groove behind the mirror *c* among the screws of adjustment; this coloured glass is for the reflected sun, and turns on a horizontal joint at *o*, and therefore may at any time be turned aside, without being removed from the groove, and lest the deepness of the colour of one glass should not suit under all circumstances, a second and a third, each of a shade lighter colour, and in frames exactly similar to *fig.* 2. may be put on instead, one of which has moreover a vertical joint near the horizontal one, by which it may be turned back entirely out of sight of the telescope. Besides these dark glasses, there is one in a small tube which slips over the eye-piece of the telescope, and guards the eye from the sun's rays when seen by direct vision. *Fig.* 3. is a microscope borne by a clamp of ivory with a spring below at P, which slips upon the limb at any point of it, and assists in reading the coincidence of the vernier with some dividing line on the limb; there is one to each vernier; these microscopes would have been better placed on the bar C, that carries the vernier, if the reading had been wanted at every observation, but as the reading is only required to be made once, after half a dozen observations successively made, it was thought better to have them detached. The circle is made firm by six radial arms braced below by long bars screwed edgewise to their inferior planes, by screws going from above, some of the heads of which are seen. As a support for this instrument, a long tube of brass of great strength is screwed into a thick plate, borne by a heavy ring, attached to the interior ends of the cross arms; this long support has a ball E and socket, which allow the plane of the instrument to be elevated to any angle with the horizontal line, and which fix the position by being tightened with a vertical screw within the tube carrying a cup of pressure that is raised as the screw is turned; the screw has also a small wheel attached to it which is actuated by an horizontal endless screw, bearing the ring F by which it is turned, so that one turn of the ring F moves the wheel within the tube the space of one tooth, and as the thick arbour of the wheel is that which has the vertical screw on its circumference, and carries the cup of pressure, it is not difficult to conceive that the ball may be loosened or fixed in the socket, accordingly as the ring F is turned forwards or backwards by hand.—The inventor intended a staff to bear on the ground, but Bird preferred a belt for the end to rest on like a standard belt, and the tube contains a stick that will draw out and fix at any convenient length to go into a hole in the belt.

In Hadley's quadrant there is an adjustment to be made for the parallelism of the two mirrors, when the point *o* of the vernier is at *o* on the limb; this adjustment is here not necessarily on any particular degree on the limb; but, what seems to be a condition in this instrument, the two mirrors are required to be put parallel, when the two verniers are so far removed from each other, as to include between them the greatest angle that is ever intended to be measured by them, a degree or two over or under does not at all affect the operations; on examining the instrument at present under our eye, we find 73° 38′ contained between the points of commencement in each vernier, so that the actual measure of this angle, when the object has suffered two reflections, will be 147° 16′, which is the greatest angle that the instrument will measure in its present state, as the points *o* and *o* of the two verniers coincide when the bars C and G are in contact, one of the verniers being an interior, and the other an exterior one. In our figure the distance between the verniers is 60 full divisions, or 120°, which our draftsman thought was a good position for exhibiting all the different parts of the instrument, consequently the mirrors are not parallel in their present position, but will become so when the telescope is carried forwards, in the order of the figures, till its vernier indicates 73° 38′ on the limb, which quantity we have said measures 147° 16′.

The mode of using this instrument may be explained thus:—Let the mirrors be placed parallel in the first place, while the vernier *k* of the arm C rests fixed at *o*, or 360° on the limb, which may be done most accurately by moving the telescope and its vernier first to 73° 38′ nearly, and fixing it, and then by making the sun, moon or star, the last of which is best, as seen by reflection, exactly to coincide with the same as seen through the unsilvered part of the glass by direct vision, and there fix it by the screw *e*; and if the two mirrors are so adjusted, as to be perpendicular to the plane of the instrument, the real body and its image will not be at one side of one another, either perpendicularly or horizontally; but if they should be so, the mirrors must be set right by the adjusting screws, and then the instrument will be fit for taking an observation; we will suppose that the angular distance between some known star and the moon be required to be ascertained; in this case the lower end of the support D is made to rest in one of the holes of the belt, and the ball is so adjusted in the socket, that the plane of the instrument may pass through both the objects; in this situation the right hand body is viewed through the telescope, and the vernier *k* being set at liberty, the bar C is brought by an uniformly slow motion towards the telescope so far, that the object seen by reflection, when followed by a proper motion of the body, and of the entire instrument, comes very nearly in contact with the second body seen by direct vision, there the screw *d* must fix the bar C and its vernier, which are now moved, the remaining quantity backward or forward by the tangent-screw *i i*, till one of the moon's limbs and the star are in exact contact; these two operations of fixing the mirrors parallel, and of effecting the contact of the two bodies afterwards, constitute what is called a *single observation*, and if the vernier *k* were now examined, the angle indicated, which we will suppose to be 30° 0′, would be half of the true distance, as the instrument is graduated, if the graduation were perfect; but if Mayer's supposition be allowed, that there is a possibility of an error of 3′ plus or minus in this single observation from imperfect graduation, then such single observation ought not to be depended upon; the same process is consequently repeated, that is, the vernier *l* remaining fixed as at first, and the time being noted of the instant of the first contact, the telescope is again made to advance, till the mirrors are parallel, as examined by a star's coincidence with its reflected image, and is then fixed by the screw *e*, the tangent-screw being again used if necessary for the exactitude of the coincidence, which is the first operation of the second observation; in the next place, the bar C, with its large mirror and vernier *k*, is again carried slowly and uniformly, as before described, till a second contact of the star with the same limb of the moon is effected, and then this bar is again fixed as before, and the tangent-screw completes the exactness of the contact, which is called the second operation of the *second observation*, which observation is here completed, as soon as the

instant

inftant of the contact is noted down; now fhould the angle be read off by the vernier *k*, it will indicate 60°, or a meafure of 120°; but fuppofe a pofitive error of 3′ to exift, the amount of two obferved angular diftances will on this fuppofition be 120° 3′, which, divided by 2, the number of obfervations, will make the angle 60° 1′ 30″, inftead of 60° 3′, which it would have been with the fame error in one obfervation; hence two obfervations diminifh the error of graduation one half; but fix repetitions of the two operations, *i. e.* fix obfervations will diminifh the faid original error fix times, and reduce it to 30″, which is the advantage peculiar to the inftrument: whenever it is found beft to view the left hand body, and to carry its image to the left hand body, the vernier *k* muft be fixed at Zero, and the telefcope muft be moved, and vernier *h* ufed in reading the angle, which is juft the reverfe of the motion defcribed. When any number of obfervations is fixed upon to be taken, the times of contact muft as often be noted down, and then the mean time is taken as the inftant of contact correfponding to the mean angular diftance, which is obtained by dividing the total arc paffed through, as read off at laft, by the number of obfervations or contacts; the readings of all the intermediate obfervations being of no importance, otherwife than as we have ufed them to explain the effect of the repeating procefs. It may be neceffary to obferve, that all the obfervations of a ftar's angular diftance from the moon, fhould be completed within half an hour, or at moft an hour, otherwife the inequality of the moon's hourly motion muft neceffarily be taken into the account, which would be a troublefome correction. By this method of diminifhing the errors of graduation, by a repetition of the obfervations taken all round the circular limb, it is eafy to fee that an error of one whole degree may be reduced to a minute at fixty repetitions, whatever may be the magnitude of the obferved angle.

Hitherto we have fuppofed angular diftances only neceffary to be meafured by this inftrument, for doing which indeed it was originally invented, but altitudes may be taken quite as well, and with the fame advantage, for the ball will turn in the focket, fo as to give a vertical pofition to the plane of the circle, or it may be held without the fupport like a quadrant, and the contact of a heavenly body with the horizon is made, as well as with the moon's limb, after the firft operation of placing the mirrors parallel has been performed; likewife a repetition of the obfervations may be carried to any number; but as the variation in the altitude of any body is not fo regular as the variation in the angular diftance between two bodies, a repetition of the altitudes with the correfponding times, unlefs made in rapid fucceffion, will not give a mean altitude with its correfponding time, and as the meridian or greateft altitude is that which is moft frequently wanted in navigation, for the fake of the fimplicity of the fubfequent calculation of the latitude thereby, the mean of a number of altitudes before and after apparent noon, will give the greateft or true meridian altitude too little. In the defcription which we have fo far given of Mayer's circle, and of its ufe, we have confined ourfelves to the reading of the vernier *k*, which indeed was all that admiral Campbell ufed, but it is evident that the vernier *h* may alfo be ufed with advantage, for the diftance between the verniers is a conftant angle, in this inftrument, of 73° 38′, or rather of its double, 147° 16′, and the reading may as well be made by this vernier as the other, if this conftant angle be fubtracted from the angle indicated; for the fake of greater accuracy therefore, it is advifable to read the whole amount of the repeated angles, from both verniers, as the author intended, and then having deducted the conftant angle from the latter reading, they ought to agree in quantity, but if there is any difference, the mean between the two muft be taken, as the true amount to be divided by the number of obfervations, and the mean angle thus obtained will be afcertained as it were by two feparate inftruments, both ufed on the repeating principle. Befides the inftrument before us, there were others made, particularly one for captain, afterwards lord Howe, but we have not been informed whether, like admiral Campbell, he compromifed the repeating principle for the beft fextant of the circular limb, to be ufed as a Hadley's fextant, or whether he perfevered in ufing it according to the original intention, notwithftanding the inconvenience of the operations during the repetitions.

The inftrument at prefent before us, we obferve, has been divided by bifections, and not by an engine, as is now the cuftom in dividing inftruments of fmall radius, for the occult dividing dots and bifections are ftill vifible by a magnifying glafs in the original circle within the graduations transferred therefrom, that are intended to be permanent: on examining the limb all round with a microfcope, by the two verniers, and alfo by examining the included conftant angle on different portions of the circle, we have not detected more than a minute of error in the graduations, fo that had Mayer been aware of fuch accuracy in the divifions inferted by a beam compafs, he probably would never have fet about his contrivance, which was invented on a fuppofition that there muft exift an error of at leaft 3′, which he propofed to diminifh to 30″ by fix repetitions of an obfervation of the moon's angular diftance from the fun, or a known ftar. The errors which we detected lie chiefly in the femicircle numbered from 180 to 360; in the firft third part of the degree 181, there is about 1′ too much, which is the cafe with one of the third parts of both 264 and 277; but as the contiguous fubdivifions are proportionably too fmall, the errors are corrected within the degree fpace, alfo the degree 279 has a third part too fmall by 1′, which is given to its contiguous fubdivifions. The dividing lines on the limb are thicker than neceffary, we think, and meafure more than a minute each, fo that the greateft error does not exceed the thicknefs of the dividing ftroke on any part of the whole limb.

The verniers too have each of them one fpace larger than the reft by about half of a minute, and what is fomewhat remarkable, it is one of the end ones in both that is too large; but in both the whole length of the fcale of 20 is exactly proportioned to the 19 thirds of a double degree, when compared all round the limb, except in the particular degree fpaces which we have above noticed, and fome few others where the error is within a minute.

It may be proper to mention, before we difmifs this account, that there is a contrivance in the inftrument we are defcribing, introduced by Bird, for giving the large central mirror a circular motion on the arm C, by means of a fide fcrew *o o* actuating the circular piece of metal *p* which bears the mirror, and which has very fine concave indentations, like thofe of a milled head, on its circumference; but as this motion, which was originally intended to adjuft for the exact quantity of the conftant angle contained between the verniers when the mirrors are parallel, is calculated to render the large mirror unfteady, we confider the addition as being of no real fervice, but on the contrary rather detrimental, provided the central mirror be placed in fuch an angle at firft, with refpect to the radial line of bar C as will allow the inftrument to meafure an angle fufficiently large for the purpofe required. We have adjufted the conftant angle to exactly 75 large divifions, or 150°, in which ftate it is now fixed and fuffered to remain, as being more convenient than an angle confifting of degrees and minutes.

 The

The inventor propofed a kind of metallic gage by which to fix the conftant angle, when once afcertained, without an operation for determining by a heavenly body the exact parallelifm of the two mirrors, but the inftrument-maker knowing that no gage could be depended upon in all degrees of temperature, did not make it a part of the appendages.

The French reflecting and repeating CIRCLE, *by the Chevalier de Borda of Paris.*

In the year 1787, the Chevalier de Borda, publifhed at Paris a pamphlet entitled "Defcription et Ufage du Cercle de Reflexion," in which is contained a particular account of his improvement on Mayer's circle, together with the ufes of a circle of his improved conftruction, and the dimenfions of its different parts, which had occupied him twelve years in perfecting. The objections which he ftated to the ufe of Mayer's circle were; that one obfervation required two operations; that the adjuftment for the parallelifm of the two mirrors was ufually made by viewing the horizon at fea, and was very often productive of error, on account of the direct and reflected line being difficult to bring into exact coincidence; that a repetition of this kind of verification is very tedious in practice; that it is difficult to make a circle fo exact, but that the parallelifm of the central mirror, in refpect of perpendicularity to the plane of the circle, fhall have a deviation in different parts of the limb, when the parallelifm with refpect to the horizontal pofitions of the two mirrors is well adjufted; and laftly, that a great number of fingle angles thus meafured by double operations, is very embarraffing to feamen. For thefe reafons, which were all real objections, the Chevalier contrived his reflecting circle, that, in the firft place, entirely difpenfed with the adjuftment for the parallelifm of the mirrors; that in the next place meafured two angles at two operations, after the inftrument was previoufly fet for parallelifm and to zero; and laftly, that was capable of being ufed on the repeating principle as well as Mayer's inftrument.

We have been fo fortunate as to gain a temporary poffeffion of one of Borda's reflecting circles made by Lenoir of Paris, of which we have had an original perfpective drawing taken, fuch as we flatter ourfelves will be readily apprehended by thofe readers, who have perufed our account of Mayer's with attention.—*Fig.* 4. *of Plate* II. *of Aftronomical Inftruments*, reprefents Borda's improved reflecting circle, No. 56, nearly in the fame pofition as Mayer's which is placed over it, and confifts of the fame parts fomewhat differently made and placed with refpect to each other; we have therefore put the fame letters of reference to both, which will enable us to fhorten our defcription of the prefent inftrument, as well as affift the reader where to find the parts referred to.

The circle A in this inftrument is much fmaller than in the preceding one, being only 5.3 inches radius from the graduated circle of the limb, and is therefore fufficiently portable by the fhort handle D, without a ball and focket or belt; it is divided into 720 larger divifions, which by reafon of the reflection of the mirror at the centre are read off as fo many degrees; and each of thefe divifions, which in future we fhall confider as degrees, are fubdived into three fmaller fpaces of 20′ each; two verniers *k* and *h*, of 20 fpaces each, on the ends of the bars C and G, refpectively, cover juft 19 of the faid fubdivifions of the limb, as is the cafe with Mayer's, from which it differs no otherwife, than as the degrees are here fingle degrees juft as they are meafured by reflection. The limb appears to be engine-divided; for we cannot difcover any original dots or bifections of a beam-compafs. The telefcope carried by the bar G is fhorter than Mayer's, and the fmall glafs *b*, half filvered and half plain, is removed from the centre to as near the circumference of the circle as can be with convenience, which pofition requires the bar G to be prolonged quite acrofs the circle, to the plane of which it is held clofe by an attached piece behind the fmall glafs, which goes under the extreme edge of the circle. This fituation of the fmall glafs conftitutes the principal improvement in this inftrument, fimple as the caufe may appear at firft fight; for an incident ray of light may now be received by the large central mirror, from either the right or the left hand fide of the fmall glafs, which glafs together with its frame, according to Mayer's conftruction intercepted the light coming from the left, and allowed only the light coming from the right to fall on the central mirror; and it is owing to this circumftance that Mayer's circle is capable of meafuring only a fingle angle at two operations, as we have defcribed, whereas Borda's circle will meafure a double one with equal eafe and expedition, as will be explained prefently. The telefcope B in this inftrument is borne by two cocks *f f* fcrewed to the bar G out of fight; thefe cocks have each an oblong aperture contiguous to the 24 dividing lines figured from *o* in the middle to 12 both up and down, which divifions are indicated by a line, marked on the folid piece of brafs which flides in the aperture of each cock, and is tapped to receive the thread of the fcrew *l f*, the head *l* of which is a milled nut over each cock, the fliding pieces bearing the lines of indication are faft to the tube of the telefcope, which therefore they fupport; the line of fight may be adjufted by thefe fcrews, not only to be parallel to the plane of the circle, but to a point at any height in the glafs *b*, borne by the bar G, either in the plane or filvered part of its furface. This mechanifm therefore is inftead of the jointed frames *f f* in Mayer's circle.—There are three pairs of dark glaffes *m*, fuch as are feen at *m* in *fig.* 5. varying in their fhades of colour; any pair of which may be ufed as circumftances may require; one of each pair is fixed in a focket by a thumb fcrew at *m*, and the other at *n*, when the angle to be meafured is pretty large; but as the frame of the glafs at *n* will intercept the incident ray, when a fmall angle between 5° 20′ and 34° to the left is meafured; another fet of dark glaffes *o*, *fig.* 5, may be fubftituted for thofe at *n*, to be fixed clofe to the mirror of the bar C, by the two thumb-fcrews, which appear contiguous to this central mirror at *o* in *fig.* 4. When a pair of the dark glaffes *m* are ufed, they muft both be of fimilar fhades of colour, that the coloured rays of reflection, and thofe of direct vifion may require the fame focal adjuftment of the eye glafs of the telefcope; but as the rays incident on the central mirror, have to pafs twice through the dark glaffes *o*, when any one of them is ufed, thefe glaffes are only of half as deep a fhade of colour as their refpective correfponding ones *m* are; the double paffage producing the effect of doubling the fhade of colour. If the glaffes *m* were placed exactly parallel to the glafs *b*, there would be a fecond reflection of the image of any object, viewed through the telefcope, and feen through the unfilvered or upper part of this glafs; to prevent which effect, the dark glaffes ftand inclined in a fmall angle from true parallelifm, with refpect to the glafs *b*, which pofition deflects the fuperfluous faint image we have juft mentioned, and prevents its entering the object end of the telefcope.

The telefcope itfelf is fix inches long and magnifies three times, with a field of view of 5° 40′, of which the quantity contained between the parallel hairs or wires of the eyepiece, is exactly 2°; it is not of the achromatic kind, and inverts the object: the glaffes are a fingle object glafs, an amplifier,

amplifier, and a single plano-convex lens as an eye-glass; the two last are put in the opposite ends of an interior tube, which contains the two parallel wires; so that the wires may be placed either horizontally or vertically by turning this interior tube a quarter round.

The clamps for the verniers of this instrument appear to be each consisting of one piece, as seen in *fig.* 4, but as they are more steady than those of Mayer's instrument, we have thought it might be acceptable to the reader to have a view of the parts of the mechanism shown separately, which, therefore, we have done in *fig.* 6. The piece *a f*, which has the vernier scale on it, is screwed by four small screws, the heads of which are seen upon the forked end of the bar C, and has an oblong slit through it at *a*; *b c i* is the tangent-screw, with the milled head *i*, tapped with a detached piece *b*, which carries an oblong spring under and parallel to the axis of the screw, to cover the oblong hole *a*, and to create some friction so as to produce steadiness of motion in the piece *b*, when the screw turns; at *e* is another piece attached to the axis of the screw, in such a way that it will not slide along it by either a backward or a forward motion, but yet will allow the axis of the screw to revolve; this piece *e* is inserted into a hole *f* in the vernier piece, and kept fast by a screw underneath, not seen; and *b* has also its projecting part inserted into the oblong aperture *a*, and is attached at its lower extremity to the piece *c c*, by a screw entering below this piece *c c*, so that the tangent-screw will move the piece *c c* along with the piece *b*, as far as the aperture *a* will allow the projecting piece of *b* to move, the screw itself in the mean time keeping its position on the vernier piece *a f*; the piece *c c* has a square sided oblong groove on its inferior surface, a section of which may be seen near the right hand *c*; into this groove the cross piece *g h* is bedded, which carries the transverse spring *h* on its end, and the fixing screw *d* entering into the left-hand hole of *c c*, which is tapped, fixes the pieces *c c* and *g h* close together, when the screw is turned one way about, but allows them to separate when turned the other way; the piece *b*, therefore, the piece *c c*, and the piece *g h*, together with the screw *d*, are all moveable as one piece along the aperture *a* by the tangent-screw *i*, while the piece *a f* of the vernier remains fixed to the bar C; but if the compound piece *b*, *c c*, and *g h*, be made fast to the limb, which is interposed between the end *h* of the piece *g h* below C, and the vernier piece *a f*, then the tangent-screw *i* will be obliged to move, and will carry the vernier with it, which is actually the case in taking an observation, when the fixing screw *d* has fixed the said compound piece, which altogether may be called the clamping piece, while the exactitude of a coincidence is finally effected by the slow motion of the tangent-screw. The other vernier on the arm G differs from this in its mechanism for clamping, no otherwise than as the bar G has only one prong of the fork to attach the vernier to.

Fig. 7 is a piece of thin brass, made black on both surfaces, called a *ventelle*, which has a small triangular hole through it, and which fits the socket *m* behind the glass *b* in *fig.* 4, to limit the quantity of light admitted directly through the unsilvered part of the glass, which it will regulate by sliding up and down the socket; it is chiefly used for terrestrial objects, to make the image as distinct as the object itself, which is an advantage not possessed by Mayer's circle. *Fig.* 8 is a bent piece of brass equal in height to the centre of the central mirror from the plane of the circle; there are two of those pieces which are called *viseurs*, and which are placed at diametrically opposite sides of the plane of the limb for examining the perpendicularity of the index mirror, the height of one viseur, seen by reflection, being compared to the height of the other seen directly. These pieces may be considered as superfluous, because the extreme edge of the limb itself, seen both by reflection and direct vision, will do as well, and with less trouble in the usual way. *Fig.* 9 is a key with a milled nut at one end, and a square hole at the other for receiving the square ends of the screws which verify the mirrors.

We have said that Borda's circle will measure the double of an angular distance, contained between two terrestrial or celestial bodies; it now remains for us to explain the manner in which this is done. On examination, we find that the constant angle contained between the verniers, when the mirrors are exactly parallel, is $167° 35'$ in the instrument before us; instead of looking at the right hand object, and of bringing the index *k* of bar C towards vernier *h* of bar G, or telescope, in taking an observation, (which would be the mode if a single angle only were wanted to be ascertained,) when the vernier *k* is at zero, the telescope, according to Borda's method, must be directed in the first place to the left hand object, which must have its image brought to coincide with the right hand object seen directly, by carrying the telescope outward from the vernier *k*, which operation will enlarge the constant angle of $167° 35'$, by the quantity of the simple angle to be ascertained; suppose this to be $30°$, then $197° 35'$ will be the distance of the verniers when the image of the left hand body is in contact with the real body to the right; this we call the first operation, by which the simple angle might be obtained by subtracting the constant angle from the angle now indicated by the vernier of the telescope, but such notice is disregarded as not being necessary; the telescope, being now clamped to the limb by the fixing screw, while the contact remains perfect, the bar C of vernier *k* is next moved by the second operation toward the telescope, which carries the image back again to the original situation, where, if the motion of the vernier *k* were stopped, the glasses would be again parallel, and the index of bar C would show $30°$, on our former supposition; but instead of stopping here the vernier *k* crosses the point of parallelism, and diminishes the constant angle by approaching the telescope, till the image of the right hand object is found in contact in its turn with the left hand body; in this situation the vernier *k* has measured the observed angle twice over, and will be found to stand at $60°$; for, first, the former contact effected by moving the telescope, in the first instance, is undone, by placing the objects in their original situation, as the vernier *k* passes the point of parallelism in moving from the right of that point, and, secondly, a new contact is made, by taking the image of the other object, and carrying it to the left hand side of the point of parallelism, hence the whole of the two operations is called the *crossed observation*, and takes in the angle twice over; once to the right and once to the left of the parallelism of the two mirrors. From this account of the crossed observation, it is easy to conceive, that it is of no importance to fix the mirrors parallel in the middle of it, because if there were an error of a minute, or even of a degree, in adjusting for parallelism at the middle of this double angle, plus or minus, the second half of the said double angle would be just as much wrong in the opposite extreme, that is, would afford an exact correction; hence there is no need of waiting for adjustment of parallelism at all; but the index may be made to pass the point of parallelism in a crossed observation without the least notice taken of it, which is the peculiar advantage of this instrument. During this explanation of the principle of Borda's circle for measuring double angles, we have said nothing of the repeating principle; but the process we have described may be repeated any number of times,

times, and the amount, as in Mayer's circle, may be read off at once on vernier k, or on vernier h, diminished by the constant included angle, which, in the present instrument, we have said is 167° 35′; or what is still better, a mean of both may be taken, to be divided by double the number of crossed observations, and the quotient will be the true corrected angle resulting from the different observations.

This method is, however, adapted more particularly to terrestrial objects, where it is generally a matter of indifference which of the two objects has its reflected image carried to the other object, so far as relates to the distinctness of the image; but in celestial observations, for which the instrument was more particularly intended, it is well known to practical astronomers, that it is preferable to bring the reflected image of the more luminous body into contact with the less luminous body seen directly, whether the former be situated to the right or left of the other; it is also equally well known, that to effect this purpose, even with a Hadley's sextant or octant, the plane of the instrument must frequently be turned towards the ground, in order to catch that body to the left which would be caught to the right, if the same plane were towards the sky; hence, the reflecting circle must have its position also inverted, by being turned over on the telescope as an axis half round, in one of the alternate operations; for, to have the advantage of a luminous reflected image, it is necessary that either the leading or following operation of a crossed observation should place the instrument in the inverted position, as the case may require; the result, however, is the same, whether the inversion be used or not, when both the image of the first, and the real body of the second object are both sufficiently distinct in the field of view of the telescope. It may appear at first sight, that, because inversion makes a motion of either vernier from the right become a motion from the left, that the reading of the limb will thereby be affected; but when it is considered that the figures of the limb itself are reversed by inversion, no difference will be found to take place; for provided, for instance, the vernier k at Zero be brought towards the telescope at the point of parallelism by a motion from the right, when the divisions are above, and from the left, when the divisions are below, facing the ground, when a horizontal angle is measured, in both cases the effect is a lessening of the angle included between the two verniers, the quantity of which is read by that vernier which has been moved. If, therefore, the object to the left be the brighter object of the two, the first or preparatory operation, in which the vernier of the telescope moves, and in which the image comes from the left hand object, must be performed with the graduated face upward, and must be the second operation, where vernier k moves after inversion, or with the same face down; but if the right hand object be the more luminous, the inversion must take place in the first instance, and the subsequent portion of the crossed observation must be performed with the divisions and scales upwards; a little practice is all that is necessary to render this process familiar, whenever both the objects are sufficiently distinct. The adjustments for perpendicularity of the mirrors are the same as in Mayer's, and the principal objections to the present construction will be stated in our account of the English reflecting circle, that owes its origin to those objections; which, therefore, we shall describe the next, though out of its order of time.

There is, however, an adjustment of the index-mirror mentioned by Borda, which, we think, is worthy of observation here, as it is an adjustment probably too much neglected by many makers of octants and sextants, to which instruments it is equally applicable, and as it is of importance in directing the maker's choice of a proper mirror. The adjustment is that which detects the want of uniformity in the thickness of the silvered glass that composes the mirror at the centre, which is essential to be noticed, for if the slip of glass is thicker at one end than at the other, it will form a kind of prism, and a deflection of the rays of light will take place, more or less, in their second passage from the back or reflecting surface of the glass, which deflection may be plus or minus with respect to the true reflected angle, accordingly as the thick end of the mirror is contiguous to or remote from the end of the telescope. Let us call the end of the silvered slip of glass next the telescope a, and its opposite end b, then the uniformity of the glass composing the mirror, in regard to its thickness at the respective ends, is thus proposed to be ascertained.

When the two mirrors are made both parallel to the plane of the limb, measure a large horizontal angle of about 120°, as contained between two remote and distinct terrestrial objects by a series of crossed observations, and mark down an accurate mean for the true angle, when the end a of the mirror is towards the telescope; then take the mirror carefully out of its frame, (we are here addressing ourselves to the maker) and place it again with the end b towards the telescope, and examine that both the mirrors be again perpendicular to the plane of the limb as before, which they must be before a second series of crossed observations, similar both in kind and number to the former series, be taken; take now the mean of the second series, and note it down also, and the difference between those two means, if nicely obtained, will be double the error of undue refrangibility of the glass of which the index-mirror is composed, half of which must be allowed for in every observation taken with the instrument with the said mirror; but as the error is proportionable to the angle observed, the quantity of it to be applied depends on the said angle, and is a variable quantity; for ascertaining which, under different circumstances, Borda has given a table in his pamphlet, which may be used with advantage, where great accuracy is required, and when the error in question is considerable; but we should recommend in preference that a more perfect mirror be substituted in this case, such as may be found on trial to require no correction, which the best instrument-makers will always take care to do. In the same pamphlet are contained various other useful tables, one of which, in particular, must be necessary, when meridian altitudes are taken by a series of crossed observations, inasmuch as it gives the variations of altitudes a little before and after the meridian passages of the heavenly bodies, and, consequently, assists in ascertaining the greatest altitudes, which a mean of the observations taken before and after the meridian passage would not of itself give truly. There is also another table of corrections for a deviation of the plane, in which the contact is observed, which may sometimes be necessary, but it is better that the due rectification of the two mirrors should supersede the use of this table also.

The English reflecting Circle, *by Troughton of London.*

We come now to treat of the reflecting circle as an English instrument, for as Bird, in constructing the first, gave it no distinguishing feature, it must hitherto be considered as a foreign production. Our countryman Troughton had formerly much experience in making the circle of Borda, and had marked with attention the inaccuracy and inconvenience of that construction; nay, had long turned his mind towards

towards its improvement before in the year 1796 he produced his first specimen.

The scientific men, and instrument makers of France, have long gone hand in hand in improving and recommending the circle of Borda; almost indeed to the total exclusion of the octant and sextant in the maritime service of that country; but the success of the English construction has hitherto been left wholly to the exertions of the individual who proposed it.

The circle of Borda, as before described, is objectionable chiefly in the following respects.

First. The two indices revolve round the centre upon bearings only equal to their own thickness, and want consequently that steadiness which is derived from a long axis, to assure the glasses and telescope to reverse in the same plane through every portion of the circle:

Secondly. The telescope being raised and lowered by two screws, the motions of which are necessarily shewn by dividing lines, cannot be acted on without much loss of time in looking at those divisions: for if one of them be screwed up or down the least quantity more than the other, the observations will be rendered inaccurate; the telescope thereby being drawn from its parallel position. In a well-contrived instrument, this adjustment, the use of which is to render the brightness of the objects apparently equal, should be performed with the greatest facility, in order to keep pace with the fleeting variations of brightness in those objects:

Thirdly. The darkening glasses are awkwardly applied; indeed the constitution of the instrument scarcely admits of a better application; they take up too much time to exchange them as the brightness of objects varies, and are therefore liable to the objection stated just above. Those dark glasses which are used in the small angles are moreover objectionable, because their position is such as in a great measure diminishes the distinctness of the objects:

Fourthly. Above all, the want of a handle on the upper side renders the observation in the inverted position of the instrument almost impracticable. Every observer, who has much used the former constructions, must have felt this want; but it fell to the lot of the author of the English construction to contrive and apply the remedy. Good observers, for want of this handle, have seldom availed themselves of the properties of either Mayer's or Borda's inventions, and of course have degraded the circle to a rank below the common octant:

Fifthly. A most embarrassing thing in the use of Borda's circle, which renders it almost useless in the night, is, the necessity of making a previous observation, from which to compute nearly the points of the limb where the indices will rest at every stage during the continued operation of repeating the angle. Some years ago the inventor of the English circle found a remedy for this inconvenience, by attaching a divided arc to one of the indices, having two stops sliding thereon; these stops being set to the apparent angle, the progress of the two indices will be alternately arrested thereby at the two relative positions of the indices, where the objects will appear near each other in the field of view. By this simple contrivance a set of observations may be managed in the dark.

Sixthly. The correction of the error of eccentricity is not certain in all cases; if the index which gives the angle has only traversed one third round the limb, whatever has been the number of observations, the mean observation may have nearly the whole of the error belonging to the measured angles charged upon it. On this index's getting quite round the limb the correction will be perfect; but proceeding further than a complete circle regenerates the error. It is true this kind of error diminishes at any given point of the limb, as the number of repetitions are increased; but is never perfectly corrected but at complete revolutions.

These are the imperfections of Borda's circle, which being built upon the fabric of Mayer's, a form ill suited to receive his invention, subjected it to error and inconvenience, and reserved it for the honour of an English artist to give full effect to one of the happiest thoughts that ever led to the improvement of any instrument.

Plate III. of *Astronomical Instruments* exhibits perspective drawings of Troughton's circle. *Fig.* 1 shews the face or divided side of the circle, and fig. 2 the back, or side of the glasses and telescope. In both of these views of the Instrument the form of the cross-bar frame, and its connection with the strong circular border, is too plainly exhibited to require a particular reference. This form of the body of the instrument was found by experiment to resist the pressure of the weight in every position, and to assure a coincidence of the image and body of the two objects to be observed at all angles when held by the different handles, and from trial of many other figures was the only one that did so.

In the middle of the frame is fixed a hollow centre, A, upwards of two inches long, having its flaunch or broad base contiguous to the back of the frame; in this the axis revolves freely: at one end of the axis is fixed the index, and at the other end the index-glass, both firmly united thereto; this is the only central motion in this instrument, and being the axis from which the circular plane is generated, the first objection to the former construction of the reflecting circle is thereby obviated.

On the back, or side of the glasses, is erected a kind of secondary frame, BB, removed from the principal frame a distance equal to the lower end of the hollow centre: these frames are united by five equi-distant pillars. Below the secondary frame all the glasses appear; and the distance below the frames affords a relief for the darkening glasses to be turned down round a joint as in the sextants and octants. This contrivance corrects the third mentioned defect. The same secondary frame allows a length of barrel, C, in which is effected a contrivance for raising or lowering the telescope, even while the observer is looking at his objects, and without the least danger of deranging the parallelism of the line of collimation with respect to this plane of the circle. Thus the second evil is prevented.

D is a handle on the divided side, but fixed to the instrument on the side of the glasses; it is attached to a brass tube, which, being bent over the edge of the circle, allows the index to revolve freely: but as in some positions of the index the bent tube would cover the limb at the point where the observation must be read off, it is readily removed by taking out the finger-screw, *d*. E shews another handle on the back, or side of the glasses, one end of which enters the centre pillar, A, as a steady pin, and is screwed fast to the frame at one of the principal crossing places of the bars. Moreover, a cock, *c c c*, on the side of the glasses and above them, receives another handle, F, the position of which is vertical with respect to the plane of the circle; it also applies to the handle, D, and in both situations occupies the line of the axis. This handle is very convenient when the line of position of the objects to be observed is horizontal, or nearly so; and when applied on the lower side affords the best hold of the instrument while an observation is read off. Thus this instrument presents to the observer in every possible position a convenient hold for either hand, and therefore removes the fourth, or chief inconvenience of Borda's circle.

The fifth objection cannot here occur, as the index does not proceed along the limb as in Borda's; it only steps forward and backward nearly to the same parts of the arc,

 during

during a feries of obfervations; therefore there is no need to calculate or make a preliminary obfervation. The index G has three branches at equal diftances, each having a vernier: by thefe verniers, if they are all read, the eccentricity or error of the centre will in every fight be perfectly corrected, which in former conftructions is uncertain, as has been fhewn in the fixth objection. By reading the three branches of the index, the fimple errors of divifion are meant to be reduced to a quantity not worth notice; for as every obfervation fhould be taken both backwards and forwards, every angle will be meafured on fix different and diftant parts of the limb, and the greateft error of the divifions, by taking a mean, will be reduced to a fixth part of its fimple value. The contrivance of the three verniers was intended as a fubftitute for repeating; but it muft be obferved, that as there is a bare poffibility that the fix readings may be all + or all —, this method of reducing the errors refts only upon probability, whereas that of repeating is a certain one.

Other parts, common to all circles of this clafs, are *a*, the index-glafs; *b* the horizon-glafs; *c* one of the glaffes for darkening the reflected object; *e* one of thofe for darkening the object feen directly; of both thefe there is a frame of three; *f* is the ufual apparatus for faft and flow motion; and *g* one of the telefcopes; *h* is the microfcope, with its illuminating reflector for reading off the parts of the divided limb, for which purpofe it fhifts from one branch of the index to another. The limb is divided all round into 720 parts, which may be called degrees, which they meafure, but are numbered only from the point of parallelifm of the glaffes, or the place where the index ftands in the annexed figures, each way to 160°, that being the largeft angle that can be meafured by this inftrument. The verniers fubdivide down to 20″, which on a diameter of 10 inches is judged fully fufficient for the feaman's ufe; but fome of larger dimenfions for obfervatories have been divided as low as 10″.

The telefcope is here fixed near one edge of the circle, and the horizon-glafs near the oppofite edge, which, admitting the rays of light to fall upon the index-glafs, both to the right and left of the horizon-glafs, conftitutes the peculiar invention of Borda, and affords the means in the Englifh conftruction alfo of obferving angles on both fides of Zero. But as this has been explained in the foregoing inftrument, it would be fuperfluous to fay more about it in this place.

A journalift, who is one of the ableft aftronomers of the continent of Europe, has ridiculed the Englifh conftruction under the appellation of *eunuch* (what we call *repeating* they call *multiplying*); but as it has really multiplied in kind to a family little fhort of 200, the baron's pun feems but indifferently pointed. That aftronomer, however, in a more ferious mood, has thought proper to fay that Troughton's conftruction has deprived the reflecting circle of every improvement; but this being no place for controverfy, we leave the charge to the fagacity and candour of the Englifh reader.

In a comparifon of the Englifh circle with the former ones, the want of repeating is the only ground that a critic can ftand on: and it would be weaknefs to endeavour to depreciate the value of that invention; but if to acquire it, a facrifice were made, either of accuracy or convenience, to a greater extent than the gain, it would be more than weaknefs; it would be folly to perfevere in it. When Mayer propofed the repeating circle, the ftate of the art of dividing was fo rude, that all muft have confidered the repeatiug property as a moft valuable difcovery; nay, it may perhaps yet be valuable in every other nation except England; but here the dividing-engine has been fo well applied, that the fmalleft inftruments, with refpect to the graduation, may be confidered as nearly perfect.

We fhall defcribe the adjuftments of this inftrument beft by copying the practical inftructions ufually diftributed with it, which are as follow, *viz.*

Prepare the inftrument for obfervation by fcrewing the telefcope into its place, adjufting the drawer to focus, and making the wires parallel to the plane, exactly as you do with a fextant; alfo, fet the index forwards to the rough diftance of the fun and moon, or moon and ftar; and, holding the circle by the fhort handle, direct the telefcope to the fainter object, and make the contact in the ufual way. Now read off the degree, minute, and fecond, by that branch of the index to which the tangent fcrew is attached; alfo, the minute and fecond fhewn by the other two branches; thefe give the diftance taken on the three different fextants; but as yet it is only to be confidered as half an obfervation; what remains to be done, is to complete the whole circle by meafuring that angle on the other three fextants. Therefore, fet the index backward nearly to the fame diftance, and reverfe the plane of the inftrument by holding it by the oppofite handle, and make the contact as above, and read off as before what is fhewn on the three feveral branches of the index. The mean of all fix is the true apparent diftance, correfponding to the mean of the two times at which the obfervations were made.

When the objects are feen very diftinctly, fo that no doubt whatever remains about the contact in both fights being perfect, the above may fafely be relied on as a complete fet; but if, from the hazinefs of the air, too much motion, or any other caufe, the obfervations have been rendered doubtful, it will be advifable to make more; and if at fuch times fo many readings fhould be deemed troublefome, fix obfervations and fix readings may be conducted in the manner following. Take three fucceffive fights forwards, exactly as is done with a fextant, only take care to read them off on different branches of the index; alfo make three obfervations backward, ufing the fame caution; a mean of thefe will be the diftance required. When the number of fights taken forward and backward are unequal, a mean between the means of thefe taken backward and thofe taken forward will be the true angle.

It need hardly be mentioned, that the fhades, or dark glaffes apply, like thofe of a fextant, for making the objects nearly of the fame brightnefs; but it muft be infifted on, that the telefcope fhould on every occafion be raifed or lowered by its proper fcrew for making them perfectly fo.

The foregoing inftructions for taking diftances apply equally for taking altitudes by the fea, or artificial horizon, they being no more than diftances taken in a vertical plane. Meridian altitudes cannot however be taken both backward and forward the fame day, becaufe there is not time; all therefore that can be done, is to obferve the altitude one way, and ufe the index-error; but even here you have a mean of that altitude, and this error, taken on three different fextants. Both at fea and land, where the obferver is ftationary, the meridian altitude fhould be obferved forward one day and backward the next, and fo on alternately from day to day; the mean of the latitudes, deduced feverally from fuch obfervations, will be the true latitude; but in thefe there fhould be no application of index-error, for that being conftant, the refult would in fome meafure be vitiated thereby.

When both the reflected image and direct object require to be darkened, as is the cafe when the fun's diameter is meafured, and when his altitude is taken with an artificial horizon, the attached dark-glaffes ought not to be ufed; inftead

inftead of them, thofe which apply to the eye-end of the telefcope will anfwer much better, the former having their errors magnified by the power of the telefcope, will, in proportion to this power, and thofe errors, be lefs diftinct than the latter.

In taking diftances, when the pofition does not vary from the vertical above thirty or forty degrees, the handles which are attached to the circle are generally moft conveniently ufed; but in thofe which incline more to the horizontal, that handle which fcrews into a cock on one fide, and into the crooked handle on the other, will be found more applicable.

When the crooked handle happens to be in the way of reading one of the branches of the index, it muft be removed for the time, by taking out the finger-fcrew which faftens it to the body of the circle.

If it fhould happen that two of the readings agree with each other very well, and that the third differs from them, the difcordant one muft not on any account be omitted, but a fair mean muft always be taken.

It fhould be ftated, that when the angle is about thirty degrees, neither a diftance of the fun and moon, nor an altitude of the fun with the fea-horizon, can be taken backward, becaufe the dark-glaffes at that angle prevent the reflected rays of light from falling on the index-glafs; whence it becomes neceffary, when the angle to be taken is quite unknown, to obferve forward firft, where the whole range is without interruption; whereas, in the backward obfervation, you will lofe fight of the reflected image about that angle. But in fuch diftances where the fun is out of the queftion, and when his altitude is taken with an artificial horizon, the fhade being applied to the end of the telefcope, that angle may be meafured nearly as well as any other; for the rays incident on the index-glafs will pafs through the tranfparent half of the horizon-glafs, without much diminution of their brightnefs.

The advantages of this inftrument when compared with the fextant, are chiefly thefe; the obfervations for finding the index error are rendered ufelefs, all knowledge of that being put out of the queftion, by obferving both forwards and backwards. By the fame means the errors of the dark glaffes are alfo corrected; for, if they increafe the angle one way, they muft diminifh it the other way by the fame quantity. This method alfo perfectly corrects the errors of the horizon glafs, and thofe of the index-glafs very nearly. But what is ftill of more confequence, the error of the centre is perfectly corrected, by reading the three branches of the index; while this property combined with that of obferving both ways, probably reduces the errors of dividing to one-fixth part of their fimple value. Moreover, angles may be meafured as far as one hundred and fifty degrees, confequently the fun's double altitude may be obferved when his diftance from the zenith is not lefs than fifteen degrees; at which altitude, the head of the obferver begins to intercept the rays of the light incident on the artificial horizon; and, of courfe, if a greater angle could be meafured it would be of no ufe in this refpect.

This inftrument in common with the fextant, requires three adjuftments; firft, the index-glafs muft be made perpendicular to the plane of the circle; this being done by the maker, and not liable to alter, has no direct means applied to the purpofe; it is known to be right when by looking into the index-glafs, you fee that part of the limb which is next you reflected in contact with the oppofite fide of the limb, as one continued arc of a circle; on the contrary, when the arc appears broken, where the reflected and direct parts of the limb meet, it is a proof that it wants to be rectified. The fecond adjuftment is, to make the horizon-glafs perpendicular: this is performed by a capftan-fcrew at the lower end of the frame of that glafs; and is known to be right, when, by a fweep with the index, the reflected image of any object will pafs exactly over, or cover the image of that object feen directly. The third adjuftment is for making the line of collimation parallel to the plane of the circle: this is performed by two fmall fcrews, which alfo faften the collar into which the telefcope fcrews, to the upright ftem on which it is mounted; this is known to be right, when the fun and moon having a diftance of one hundred and thirty degrees or more, with their limbs brought in contact juft at the outfide of that wire which is next to the circle; remain the fame juft at the outfide of the other wire; their being fo in both fituations is the proof of adjuftment.

The inftrument by the prefent maker which we obtained a temporary poffeffion of for examination, has been fome time in ufe at fea; we have examined the readings by all the three verniers, at the ends and middle of every half fign with great care, by the help of a microfcope with an illuminating reflector, and did not detect a difference between any two readings of more than 40″, which is much lefs than we expected, notwithftanding the nicety with which we previoufly knew this maker's inftruments have long been divided by an engine belonging to himfelf; for when we confider that the three-armed piece of the verniers may be liable to have an eccentricity, as it refpects the circle, the difference we have mentioned may be taken as the whole amount arifing from the eccentricity of the vernier bars and of the inequality of the divifions taken together.

Mr. Troughton, we have feen, has adopted three verniers to effect the correction of eccentricity, which have each 20 fpaces equal to 21 on the limb, and which we have faid perfectly correct this error; but as captain Mendoza has afferted in his paper contained in the "Philofophical Tranfactions of London for the year 1801," that two verniers placed oppofite one another correct the eccentricity better than any other number, nay, that "a greater number ought not in any cafe to be ufed;" and alfo as we find that Borda has preferred *four* verniers in his repeating circle without reflection, which we fhall fhortly defcribe; we feel it incumbent on us, after what we have faid, to prove the accuracy of three verniers for correcting the eccentricity of their pofition, and alfo to fhew the probability there is of their correcting moreover the inequalities in the divifions of the divided circle. We thought it would be of importance to have the reafons of Mr. Troughton himfelf for having preferred three verniers to any other number, and therefore we wrote to him on the fubject; to which inquiry his reply was nearly in thefe words, which we think worthy of public notice; viz. "The eccentricity of a circular inftrument fuppofes the divifions to be in a true circle, but that the index revolves round a centre at a diftance from that which the divifions of the circle radiate from. Now it is plain that two oppofite indices will correct this kind of error perfectly; and it is equally true, though not fo obvious, that three indices will do the fame."

If we fuppofe a circle to be compreffed on one fide, and elongated on the other, *i. e.* transformed into an ellipfe, but having the index revolving round a point bifected by both the long and fhort diameters; in this cafe oppofite readings fhew no error, and therefore correct none, notwithftanding the end and fide divifions are altered by the compreffion, becaufe the alternations correfpond at the oppofite ends of any diameter; but three verniers, though they do not afford an exact mathematical correction, yet approximate extremely near to it.

If the inftrument were both elliptical and eccentric, like the orbit of a planet, oppofite readings would correct that part of the error which arifes from the eccentricity, but would leave the elliptical error uncorrected; but three equidiftant readings would entirely correct that part of the error which arifes from eccentricity, and would alfo approximate towards the correction of the elliptical error likewife. Four readings at right angles to each other do no more than two oppofite ones, but do the fame thing twice over; nor are fix better than three for the fame reafon. I have not tried five readings, but I dare fay they will correct for eccentricity, (which I fancy every number, odd or even, greater than unity, will do), but I have no doubt of their falling fhort of correcting the elliptical error fo well as three do."

We have no need, however, to reft the proof merely on the authority of this quotation, the comparifon is capable of geometrical demonftration fo far as relates to the eccentricity only, and with refpect to the inequality of the divifions, or what is here called the elliptic error, the tables of the planetary orbits will afford the means of comparing the errors alfo which arife from a fcale of divifions analogous to the equated daily motions of a planet, which Mr. Troughton has alluded to in his letter in confequence of our having firft fuggefted the analogy between the eccentric index of a graduated circle and the radius vector of a planet's orbit.

Let *fig.* 1 of *Plate* IV. of *Aftronomical Inftruments* reprefent a graduated circle with two oppofite verniers; let *a* be the centre of this circle, and *b* the point out of the centre, round which the bar of the two verniers revolves; and let the diametrical line 0° 180° pafs through the points *a* and *b*; now it is evident, that if this line reprefents the bar of the verniers, one being at 0° and the other at 180°, there will be no error fhewn; the fame would be the cafe if the bar were reverfed; but fuppofe the end now at 0° to move forwards to *c*, round the eccentric point *b*, and the end at 180° to *d*; in this new fituation it is equally evident, that the circle would not be bifected into two equal halves; for the femi-circle, *ced*, would be lefs than the femi-circle *dfc*, by the two fmall arcs *gc* and *dh*; again, it is equally clear that the point *c* of the vernier bar would be too forward by the arc *gc*, and the end *d* too backward by the arc *dh*, which is fimilar and equal to the former: therefore, in this pofition of the oppofite verniers, it is evident that the + error *gc* is an exact balance for the — error *dh*; this evidence refults from the nature of the figure, for as the four angles 0° *ag*, 0° *bc*, 180° *bd*, and 180° *ah*, are all refpectively equal to each other, and the dotted diametrical line *hg* parallel to the line *dc*, the arcs *gc* and *hd* are neceffarily equal to each other, the one pofitive and the other negative, as they are fituated with refpect to the index-bar *dc*.

Again, fuppofe the end *c* of the index-bar carried forwards to *e*, at right angles to its original fituation, here the demonftration is equally true, and the error is a maximum, the arc 90° *e* being the pofitive error, and *f* 270° the negative one, which two are as before equal to each other; and in the fame way it may be proved, that the two oppofite errors will correct one another in any other fituation of the eccentric bar of the verniers, where the errors in the femi-circle to the right of 0° will be all pofitive, and thofe in the femi-circle to the left will be all negative, fuppofing the verniers to move agreeably to the divifions in the direction of 0° 90° 180° and 270°.

Let us now try what three verniers will do in correcting the errors of eccentricity.

In *fig.* 2 of the fame *Plate*, let 1, 2, and 3, reprefent the three verniers revolving round the eccentric point *b*, as before, at 120° diftance from each other, and let No. 1 ftand at 180° of the circle, then the other two verniers will ftand at equal diftances at each fide of the point 0°, namely at 60° and at 300° of the graduated circle; in which fituation No. 1 has no error, but No. 2 has a minus error of the arc 2 *f*, and No. 3 exactly a fimilar plus error *e* 3, on account of the dotted lines *af* and *ae* being parallel to the lines *b* 2 and *b* 3, reprefenting the two arms of the verniers 2 and 3; the correction is therefore complete.

Secondly, let the arms of the verniers be placed as in figure 3, where the errors are the greateft poffible, by reafon of the arm 1, or arm of the pofitive correction, being at right angles to the line 0° 180° paffing through the centre and alfo the eccentric point *b*; as Mr. Troughton very juftly faid, the correction here is not fo obvious; it is, however, demonftrably juft. What we have to prove is, that the pofitive arc 90° 1 is equal to the fum of the two negative arcs 2 *f* and 3 *e*: the proof may be had thus; from the centre *a* demit the fmall perpendicular *ad*, which will be equal to the chord of the fmall arc 3 *e*, alfo demit the perpendicular *bc* from the eccentric point *b*, which will be the length of the chord of arc 2 *f*; *ba* is of itfelf the chord of the pofitive arc 90° 1: now, in the firft place, we have given in the fmall right-angled triangle *abc*, right-angled at *c*, the angle at *a* equal 30° (120° — 90°) to determine the fide *bc*, which, if we make *ab* = radius, will be the fine of 30°; likewife in the fimilar right-angled triangle *abd*, right-angled at *d*, we have the angle at *b* given equal 30° (alfo 120° — 90°) to determine the fide *ad*; but by reafon of the fimilarity of the two triangles, which have a common hypothenufe, the fide *ad* is alfo the fine of the angle *abd* to the fame radius, and therefore equal to the fide *bc* of the former triangle; hence the fum of the two fines of 30° each ought to be equal to radius, if the correction be perfect; but the fine of any angle doubled is the chord line of double that angle, therefore double the fine of 30° is equal to the chord of 60°, which is always equal to radius in any circle; confequently the correction in this pofition of the verniers is alfo perfect.

Thirdly, let us fuppofe the pofition of the verniers to be as in *fig.* 4, fuch, that No. 1 ftands halfway between 90° and 180°, *viz.* at 135°; then No. 2 will be at 255°, and No. 3 at 15°; fo that the errors of No. 3 and 1 will be plus, and that of No. 2 minus; in this pofition we have firft the three angles of the triangle *abe* given to determine the relative magnitudes of the fides, of which *be*, equal the chord of 1 *f*, is wanted; the angle *fa* 180° (= 1 *b* 180°) is known to be 45°, confequently the angle *abe*, its complement, is alfo 45°, and if the line, *ab*, be made radius, the required line *be* is the fine of 45°; alfo in the triangle *abd*, right-angled at *d*, the angle at *b* is 15° (= 180° — 120° + 45°), and the fide *ad* is the fine of 15° to the fame radius *ab*; likewife in the right-angled triangle *abc*, with the right angle at *c*, the angle at *a* is given = 75°, (= 120° — 45°) and the required fide *bc* is its fine, equal to the chord of the negative arc 2 *g*, which is taken as a balance to the two pofitive arcs *f* 1 and *h* 3. If now we take from a table of natural fines the three determined quantities, we fhall have

Nat. fine of 45°	-	-	+ 7071068
Nat. fine of 15°	-	-	+ 2588190
			+ 9659258
Nat. fine of 75°	-	-	— 9659258
		Uncorrected error	0000000

Hence

Hence the correction is here likewise perfect; and the method we have last used is equally applicable to any other position of the verniers that can be given them in the circle; *i. e.* the natural sines of the angular distances from the nearest points 0° or 180°, put down with their proper signs, will always be found to afford as perfect a correction for the simple eccentricity of the indices, as if two only had been used. But Mr. Troughton has said that his three verniers approximate, moreover, very nearly to the correction of the inequalities of the divisions, or what may, by analogy, be called the elliptic error, where we suppose the divisions gradually increasing and decreasing alternately in magnitude to and from certain points in the circle; this source of errors, being a contingent one, cannot so well be exemplified in a state separate from the errors of eccentricity: we may, however, take a case in which both sources of error exist together, and try how three verniers will succeed in correcting both at the same time.

For this purpose we propose to avail ourselves of the orbit of a planet with small eccentricity; such, for instance, as that of Venus, where the eccentricity is only $\frac{1}{142}$ part of radius; the form of which orbit, therefore, does not sensibly vary from an eccentric circle. According to the elliptic hypothesis of bishop Ward, if a body should move equably in one focus of an ellipse, an eye fixed in the other focus would view it moving unequably very nearly according to the laws of true planetary motion; so much so, indeed, that where the eccentricity is small, it may be taken as exactly so, without sensible error: but the distance between the two foci of an ellipse is equal to double the eccentricity; therefore a single index moving round a point out of the centre of a circle will have a series of errors alternately increasing and decreasing in quantity, exactly like the *equation of the centre* of a planetary orbit, excepting that the scale of errors will be only *one half*, at each point of the eccentric circle, what they would have been if the index had moved round a point at double the distance of the quantity expressed by the circle's eccentricity. Hence, if we take the scale of equations of Venus, as calculated by Dr. Halley, they will afford the ready means of trying the effect of three verniers used in a circle with an eccentricity equal to *twice* that of Venus's orbit; namely, in which the eccentricity is $\frac{1}{71}$ of radius; and in which the divisions alternately increase and decrease like the diurnal spaces in a planet's orbit.

We have taken the trouble of arranging the table of Dr. Halley, which contains the mean anomaly and corresponding equations of Venus, in such a way, that when No. 1. of the three verniers stands at any degree of distance from the aphelion point (or end of a line passing through the eccentric point) in Column 1. No. 2. of the verniers will then be at the proper degree in Col. 2. 120° forwards; and also No. 3. of the verniers will be at its proper number in the same horizontal line in Col. 3. 240° forwards; likewise the equations standing in the same line in the second set of three columns, marked also 1, 2, and 3, agreeably to their corresponding distances, will be the corresponding *errors* of the respective verniers in that situation; two of which errors will be − and one +, or two + and one − always: then if the three errors, which we have called equations, be added together, in such a way that their signs may counteract one another algebraically, the remaining portion, if any, is the quantity of the uncorrected error, which we have inserted in the last column, where it will appear that in no one point round the circle is there an uncorrected error of more than 2″; and what may be considered as a proof of the truth of our arrangement, and also of the calculations, the + and − errors, being each in the whole amount 33″, annihilate one another.

The conſtruction and uſe of this table will be very obvious when we have exemplified one poſition of the verniers. Suppoſe the principal vernier, which has got the tangent-ſcrew, to be made to reſt at 20° (which is 40° in the circle, as it is divided into 720°), and ſuppoſe that it be required to know the three reſpective errors of the three verniers? Look at 20° in Col. 1. of angular diſtances, and there will be in the ſame line the diſtances of the other two verniers 140° and 260°, and in the columns 1, 2, and 3 of equations, there are $-16' 17'' - 31' 3''$ and $+ 47' 20''$; but the ſum of the *minus* quantities is equal to the *plus* quantity, therefore the poſitive error of the third vernier exactly balances the amount of the negative errors of the firſt and ſecond verniers; conſequently the correction is perfect, and in the laſt column are a couple of ciphers.

Again, ſuppoſe the firſt vernier ſtanding at (the double of) 40° with an equation of $- 30' 39''$, then the ſecond will reſt at (the double of) 160°, with an equation of $- 16' 33''$, and the laſt vernier will reſt at (the double of) 280°, with an equation of $+ 47' 12''$, which ſum is exactly a balance for the amount of the other two negative ſums, and the uncorrected error is, as before, nothing.

The few very minute errors which appear in the laſt column may be attributed, perhaps, to a want of perfect accuracy in the computation of the table, which is not carried to decimal parts of a ſecond, rather than to a want of accuracy in the mode of applying the verniers; becauſe the change from plus to minus, and back again, would not have been ſo frequent, if the errors had been owing to the mode of detection.

When two verniers only are uſed, it is equally eaſy to aſcertain from the table the correſponding equations and relative uncorrected errors; thus at 20°, as before, which is read 40° on the inſtrument, by reaſon of the reflection of the mirrors, the equation is $- 16' 17''$; and at $20° + 180° = 200°$, it is $+ 16' 33''$, ſo that the uncorrected error is $+ 16''$; thus we find that the correction with only two verniers is not perfect at any other points of the eccentric circle, except at 0°, 90°, 180°, and 270°. At 45° this uncorrected error is a maximum, *viz.* 25″ with $\frac{1}{71}$ of eccentricity, but it gradually decreaſes both ways to 0° and 90°; the ſame obſervation is true of the points 135°, 225°, and 315°, which are each 45° diſtant from the beginnings of the other three quadrants reſpectively; ſo that on the whole the ſcale of uncorrected errors with two verniers aſcends four times to a maximum, and deſcends as often during the whole circuit; which is a ſufficient proof that two verniers are by no means ſo accurate as three for the elliptic error, in our planetary trial; and as four verniers correct only as two pair of oppoſite verniers, they are alſo inferior in accuracy to three, where the correction appears as perfect as could be wiſhed.

We are free to confeſs, however, that accurate as three verniers are for all caſes of eccentricity and unequal diviſions which are at all likely to occur in the conſtruction of an inſtrument, yet there is a limit beyond which their accuracy ceaſes: for inſtance, if we ſuppoſe the eccentricity and radius of an eccentric circle as 4 to 10, which would have a ſet of equations equal to thoſe of Mercury's orbit, including the eccentric and large elliptic errors, the maximum of uncorrected error, when three verniers are uſed, would be as much as 46′, but when two only are uſed, it would be very nearly 6°, which diſparity ſhews ſtill more clearly the advantage that three verniers have over two, even in an extreme caſe. This mode of aſcertaining the preference to be given to a certain number of verniers, is, we believe, an original one; which is our apology for its introduction here at full length.

The reflecting circle which we have examined has a circle of ſolid ſilver let into, or, we believe, melted into a groove in the braſs limb, which renders the diviſions diſtinctly viſible through the microſcope, though they are too delicately made for the naked eye to read. The ſtrokes appear not to be more than one-third of the thickneſs of thoſe which we have had occaſion to examine before in Mayer's, and particularly in Borda's circle. There are three teleſcopic tubes for viewing an object, one for celeſtial purpoſes that has two powers, and a couple of croſs hairs or wires in each; a ſecond, which does not invert, for terreſtrial objects; and a third, which is only a ſimple tube, for confining the line of ſight. The parts appear to be all as ſteady and perfect after uſe, as they were when the inſtrument was new. After the conſideration which we have here given to the conſtruction of Troughton's reflecting circle, we ſhould be guilty of a ſpecies of ſcepticiſm, if we heſitated to pronounce it the beſt inſtrument that has hitherto been made for taking the lunar obſervations accurately, and for the other purpoſes of nautical aſtronomy. When this inſtrument is uſed on ſhore, the maker packs up an artificial horizon of quickſilver, and a claw-foot ſtand, as a ſupport, which ſcrews into the cock inſtead of the handle, and relieves the obſerver greatly when angular diſtances are meaſured.

The reflecting and doubly-multiplying CIRCLE, *by Joſeph de Mendoza Rios, Eſq. F.R.S.*

We have already given a brief notice of captain Mendoza's improved circle, and have ſaid that it is different from the one which he publiſhed in the Philoſophical Tranſactions of London in the year 1801, the account of which was copied into Mr. Nicholſon's Journal (vol. i. 8vo. ſeries); we ſhall therefore, without further preface, proceed to deſcribe its preſent conſtruction and manner of being uſed.

In all the circles which preceded the preſent one, there was but one principal circular plane which held the graduations indicated by the verniers of the index-bars, but here are three principal circular parts, two moveable round a common centre, and one concentrically fixed; alſo, what will be conſidered as a further peculiarity, the bar which bears the central mirror, and which has uſually the vernier, or one of the verniers where there are more than one, has here no vernier attached to it, but is uſed to convey the verniers and a circle of 360° alternately to the right and left of their original ſituation, by a vibratory motion ſomewhat analogous to the motion of a pendulum rod, alternately laying hold on one and letting go the other, during a ſeries of croſſed obſervations. *Fig.* 5 of *Plate* IV. is a repreſentation of one ſide of the doubly-multiplying circle, in which the frame, the diſpoſition of the glaſſes, and the application of the handles, are preciſely like thoſe of Troughton's circle, juſt deſcribed, and therefore need not be again explained. C is the fixed circle, uſually called the limb of the inſtrument, over which is placed a ſecond circle D, and alſo over that a third one E; the two latter of which move freely and ſeparately round the centre of the inſtrument; above the laſt circle E the index F has its ſituation, and carries at the low end of its axis the index-mirror, which being at preſent at the under-ſide cannot be ſeen in the figure. The fixed circle C has its inferior ſurface divided to the right and left into two ſets of diviſions as far as 140°, like two ſeparate ſextants, their reſpective zeros commencing not at the ſame point, but at the diſtance from one another of the breadth of the index, ſo that one of them touches one edge of the index when the other touches the other at the divided part of the limb; on theſe two portions of the circular limb ſlide two ſimilar ſtops, *a* and *a*, which may be made to remain in any given points. The index-mirror and horizon-mirror are juſt parallel to each other when the end of the index F occupies the ſituation between the two zeros; and as it is generally known pretty nearly what the angular distance of two heavenly bodies is when a lunar observation is made, these stops may be slided along the right and left divisions of the limb respectively till their inner edges stand on the supposed degree of angular distance from their zeros respectively, in which situations they will serve as guides, in the night particularly, for fixing the index alternately, in a crossed observation, in order to find the places of successive contact more conveniently than they could be found without some such rough guide; nor will these stops be serviceable for the first crossed observation only, but for every subsequent one; seeing the successive observations require not the index to have any other than alternate, backward and forward motions between the two stops, how often soever repeated. The circle D is nicely divided into 360° and their subdivisions, and the adjoining circle E carries two verniers, A and B, diametrically opposite each other, which read off to 10″. On the index F is the usual tangent-screw for procuring a slow motion when the index-bar is clamped to the limb, which clamping is effected by the action of a small lever *c*. There are, moreover, four other clamps with fixing-screws that have milled heads, which may be called dead-clamps, and which open by means of their own springs when their fixing-screws are turned back, but lay hold of their respective moveable circles when acted on by the finger or fixing screws. The clamps *d* and *g* are attached fast to the fixed circle C at opposite sides, and the clamps *e* and *f* are attached to and carried by the index F; the clamps *d* and *f* clamp the upper circle E to the limb; and *e* and *g* clamp the lower one D. Also when an observation with the motion of the index and its mirror to the left, *f* and *g* must both be fast, but *d* and *e* both loose; on the contrary, when the motion of the index is to the right, *d* and *e* must be fast, and *f* and *g* loose. The heads of the clamps *d* and *e* have each a protuberance or knob, by which they may be easily distinguished in the dark from those on the other side. In making an observation with an instrument of this construction, which appears more complex than it really is, the reader may now conceive, that when the clamp of the index has seized one of the two moveable circles and carried it to the stop on the right, where it is deposited and clamped fast, and then has taken up the other and brought it back to the left the same distance, before it is deposited in its turn, which two alternate motions complete two crossed observations, one to the right and the other to the left, the verniers have departed from their original situations, with respect to a given point on the divided contiguous circles, just as many degrees as are equal to two crossed observations, or four simple angular distances; for the verniers moved from the original point, which we will suppose to have been zero, one half, and again zero of the divided circle moved from the vernier, by a motion in a contrary direction, the other half.

The minutiæ attending the taking of a series of crossed observations may be thus explained more fully; in the first place slide the stops to the reputed angle to be measured, which we will suppose to be 50°, as read on the under side of the fixed circle C, and fix them there, one at each side of their respective zeros; let the index for the present remain at the point of parallelism, which we have said is between the two zeros on the inferior surface of the fixed circle; in the next place arrange the two moveable circles so that vernier A of the circle E may be beyond the nearest stop, and may have its zero coincident with zero of the circle D divided into 360°, in which situation fix the two clamps *e* and *f* of the index, and carry it with a quick motion to touch the stop on the right, and having fixed it by the lever *c*, complete the contact by the tangent-screw of slow motion, and the instrument is then in a state of rectification, if the glasses are truly placed, for beginning a series of crossed observations; for as both the clamps *e* and *f* of the index were made fast while it was at the point of parallelism, when the index moved to the right it brought both the moveable circles along with it, without altering the respective positions of vernier A and zero of D. The index has first to move from right to left as seen in the figure, therefore the clamps *d* and *e* must be both loose, and also that of the lever *c*, and the clamps *f* and *g* fast; but *f* is a clamp of E the vernier circle, and *g* one of D, the graduated circle; therefore when the index moves the whole space of a crossed observation to the stop on the left, it leaves the graduated circle D behind fast, and takes the verniers along with it; suppose the second contact to be completed by the tangent-screw again as before, then the vernier will read off in this situation 100° more or less, the amount of the crossed observation; but the whole circle is divided into only 360° instead of 720°, as Borda's is, the observed angle may consequently, though a crossed observation, be considered as the simple angular distance taken as a mean of two successive simple angular distances, if there had been 720° in the circle, agreeably to the division of an Hadley's octant or sextant; but it is not necessary to read off yet. Change now the state of all the clamps by fastening *d* and *e*, and loosening *f* and *g*, and carry the index back again to the stop on the right; during this motion of the index the verniers being fixed by *d* will remain behind, and the graduated circle D being clamped by *e* to the index, will now, in its turn, move along with it the exact space of the second crossed observation, and the vernier A will read off 200° more or less, which is four times the angle required to be measured; and this quadruple of the angle has been obtained by two crossed observations made alternately to the left and to the right, without any useless motion of the index; which result at this stage of the series of crossed observations explains the reason why the instrument is called not only a reflecting but also a doubly-multiplying circle, for we have seen that it doubles the simple angle required to be measured at each crossed observation taken both backwards and forwards any number of times. The quadruple angle however is read off, as being only double, by reason, as we have before seen, of the circle having only 360°. This process of alternately fixing and releasing the two pair of clamps, and of moving the index as many times alternately back and forwards between the stops, and ending with as many exact contacts by the help of the tangent-screw, will give a final result, as read by the vernier A, which divided by the number of crossed observations used, exclusive of the angle of primary rectification, will give as a quotient the true distance sought, which distance will be the more accurate the greater the number of crossed observations. Should the second vernier B be also read off, the mean of the two results will be still more accurate, inasmuch as not only the inequalities of simple division will be partly corrected, but also the eccentricity of the divided circle D completely, if there should happen to be any. Of course the mean of the times must be taken in the use of this instrument as well as in Mayer's and Borda's, but as the expedition with which a series of observations may be made, will be much greater in using this instrument, noting the times of the first and last contact may be sufficient, when the observer is expert and has no interruption; but perhaps it will be the safest method to mark down the times of each successive contact. If the errors of eccentricity and of unequal divisions had not been so perfectly corrected by Troughton's three verniers, and if instruments were not now divided with an almost incredible degree of accuracy, we should have felt disposed strongly to to recommend Mr. Mendoza's inſtrument in preference to any other one for meaſuring large angles accurately; particularly if we could perſuade ourſelves that the alternate clamping and unclamping, many times repeated, did not in ſome degree affect the accuracy of the readings; but under the circumſtances in which this inſtrument is produced, we leave to the public and to future experience the determination how far it may be put in competition with its predeceſſor, or claim a preference over it. At all events, Mr. Mendoza deſerves well of the public for this as well as for former labours to benefit the intereſts of navigation.

Aſtronomical CIRCLE *by the late Jeſſe Ramſden.*

Profeſſor Gieuſeppe Piazzi, the celebrated aſtronomer of Palermo, who firſt diſcovered the new planet which bears his name, publiſhed a work in two folio volumes in the Italian language, the title of which is "Della Specola Aſtronomica," &c. in which work the author has given a very minute account of all the different parts of Ramſden's firſt aſtronomical circle, as made for him, that is capable of taking altitudes and azimuths at the ſame time, and alſo of being uſed as a tranſit inſtrument occaſionally when placed in the meridian. It would render our account of this inſtrument too long, if we were here to make and introduce a tranſlation of Piazzi's deſcription of all the minutiæ of the different parts and ſections at full length; but we ſhould hold ourſelves wanting in reſpect to the memory of an excellent inſtrument maker, if we did not give a deſcription at ſome length of an inſtrument, which though probably not the beſt that has been made, yet was the firſt of ſuch conſiderable extent, and has in its conſtruction an union of various contrivances, many of which were at the time original.

Mr. Piazzi informs us, that Ramſden twice undertook the taſk of conſtructing the aſtronomical circle, and as often abandoned it; but at length in January, in the year 1788, he entered on the buſineſs in earneſt, and completed his labour in Auguſt 1789. The whole inſtrument, which is repreſented in perſpective in *Plate* V. of *Aſtronomical Inſtruments*, may be divided into ſix principal parts, with their appendages; 1. the vertical axis, and azimuth circle; 2. the ſuperior ſupport of the vertical axis; 3. the inferior ſupport of the ſame; 4. the baluſtrade; 5. the achromatic teleſcope, and vertical circle; and 6. the three microſcopes with their micrometers in the foci of their eye-pieces. For the ſake of order we will give an account of the parts nearly in this ſucceſſion accompanied by occaſional remarks.

The vertical axis of Ramſden's circle is compoſed of various parts, which revolve together, and which may be conſidered, when firmly united, as one piece; at the lower end is a cone T inverted, the ſmalleſt diameter of which is five inches, where it is attached to the azimuth or horizontal circle with ten conical radii, and the greateſt diameter is 14.2, where it is fixed to the oblong ſtage of braſs A; which ſtage is further ſtrengthened by gibbet pieces, at the four corners. The azimuth circle is three feet in diameter, divided into 180° twice over, and each of the degrees again into ten ſubdiviſions of 6′ each. The extreme inferior end of the axis, below the azimuth circle, is a ſmall cone of hard ſteel. On the ſtage A are faſtened four ſtrong braſs pillars, each $6\frac{1}{2}$ feet long and $3\frac{1}{2}$ inches in diameter, deſignated by the letters C C C C, and placed near the corners of the ſtage A, which is 25.3 inches by 16.8. Above the ſuperior ends of theſe four pillars, is another ſtage B of ſimilar dimenſions, in the centre of which is a tube ſtanding up, which conſtitutes the upper pivot of the axis: at each ſide of the central tube of this upper ſtage is an opening cut, which nearly divides the ſtage into two, except at the middle and two extreme edges, which edges are made firm by lateral connecting pieces: the uſe of the open parts of the upper ſtage is to admit the object end of the teleſcope to view ſtars near the zenith.

The two large pillars, each 7 feet high, and 4 inches diam. aſcending from marble baſes on the floor of the obſervatory, and terminating with a large arch, which connects their ſuperior ends, conſtitute a part of the ſuperior ſupport of the vertical axis; two ſimilar pillars with a ſimilar arch croſſing the other at right angles are left out of the drawing, but may eaſily be conceived to be ſtanding over the other diagonal of the marble baſe, and fixed in the dark circles which are ſeen at the reſpective corners; at the top of the arches, however, a croſs or piece of four ſtraight bars is ſcrewed to the four portions of the diſcontinued arches, and a hole in the centre of this uppermoſt croſs piece, receives the tubular pivot of the vertical axis. The lower ſupport of the vertical axis conſiſts of three concentric circles of iron, laid one over another on friction rollers; the uppermoſt of which bears the inferior pivot of the axis, and the other two have each an adjuſtable motion, one from eaſt to weſt, and the other from north to ſouth, effected by the univerſal joints, ſeen without the baluſtrade at 90° from each other, which joints have handles at one ſide, and each a horizontal ſcrew at the other, which ſcrews, acting as preſſing ſcrews, move the large iron circles in their reſpective directions, when the axis is to be placed exactly perpendicular to a horizontal line drawn in any azimuth.

A more particular deſcription of theſe concentric iron circles of adjuſtment, for perpendicularity of the vertical axis, would not be intelligible without ſeparate plans, ſuch as are given in Mr. Piazzi's *Plate* II.

M is a mahogany circle placed on the uppermoſt iron circle; its diameter is 3 feet 2 inches, and its thickneſs 3 inches. On this circle of wood is ſurmounted a baluſtrade of metal, R R, compoſed of a ſuperior and inferior large ring, of each 3 feet diameter, connected by 20 cylindrical pillars, each of one inch diameter, and 13 inches high; this baluſtrade defends the azimuth circle, and ſerves to give either a ſlow or quick motion from it to the axis of the inſtrument, by means of the clamping mechaniſm, connected with an univerſal joint, of which the handle Q only is ſeen in the figure, but which may be apprehended from what has been ſaid of this kind of mechaniſm, when we deſcribed Borda's reflecting circle and its clamps with tangent ſcrews. The microſcopic micrometer N, which reads off the graduations of the azimuth circle, is alſo carried between two of the pillars of this baluſtrade, together with the ſubjoined reflector of ſilver for the illumination of the dividing marks of the azimuth circle: the field of view of the compound microſcope contains but a very ſmall ſpace of the image of the divided limb; it was therefore found neceſſary, not only to mark every degree with ten ſucceſſive Arabic numerals, and alſo each tenth ſpace, with larger numerals of the Roman character, but alſo to inſert *points* for diſcriminating the ten ſubdividing lines, thus, ı ı ı ı ı ı . .. ., ... ı ı ı ı ı, which are counted 0, 1, 2, 3, &c. the diſtance between each of which we have already ſaid is 6′, therefore the correſponding values are 0′, 6′, 12′, 18′, 24′, &c. up to a degree, as read without the aid of the micrometer.

The compound microſcope N has the mechaniſm of the micrometer in the point where the focus of the eye-glaſs, or perhaps we ſhould rather ſay, where the united focus of the glaſſes of the compound eye-piece, meets the image of the ſubdiviſions of the limb, as formed in the tube by the object lens; this mechaniſm is rather complex, and cannot be be very clearly apprehended perhaps by a mere verbal defcription; it confifts of two parallel horizontal plates of metal having each an oblong hole along its middle, the upper of brafs, and the lower of fteel; the brafs one is divided into ten fpaces of each 1′, counted each way from zero, which is a point in the middle, and is moveable feparately by the horizontal fcrew on the left hand; the fteel plate carries a crofs hair or wire, and is adjuftable to the right or left by a fcrew of 70 threads per inch, which has a nut, as a head, divided into 60 equal parts, one of which parts correfponds to a *fecond* of a degree; this divided head is placed at the right hand of the microfcope, fo that one of the two fcrews cannot be miftaken for the other, and both may be held at the fame time, and turned by the feparate hands of an obferver, if neceffary. To prevent a lofs of motion in the fcrew of the divided head, or micrometer fcrew, a fpring of contrary preffure is applied in conftant action, which makes the crofs wire move backwards or forwards, without the lofs of even a *fecond*, as counted on the divided head.

The microfcope as ufual has two adjuftments, one for the object lens to make the image fall diftinctly on the micrometer's thread and fcale, and another for the eye-piece to render this image clear to the eye; alfo the micrometer has two adjuftments, one to adjuft zero of the fcale, under the eye-piece, to zero of the image of the divided limb; and the other to fet zero on the divided head to zero on the faid fcale, confequently to zero alfo on the divided limb: thefe two latter adjuftments are effected by the different fixing fcrews, which are invifible in the figure.

The vertical circle has not its dimenfions given by Piazzi in his account, but we learn from a French notice taken of this inftrument in another place, that its diameter is five feet, which correfponds to the length of the telefcope of which Piazzi fays the focal length of the object glafs is five feet; the circumfcribing boundary of the circle, correfponding to the felly of a wheel, is formed of two feparate rings, united in various equidiftant points by parallel cylindrical pieces, fo that the appearance of the compound piece is that of a circular ladder; which form gives ftrength without great addition to the weight. On the plane of one of thefe rings is firmly fixed, Piazzi fays foldered if we underftand him rightly, a third circle, which contains the lines of graduation, which lines are faintly feen in the figure. The central piece, or nave of the wheel, into which the fpokes, or radii, are faft, is a fegment of a cylinder of caft brafs, nicely perforated in the middle, and the fpokes are compofed of eight metallic cones and the telefcope, which paffes through the nave and forms two more. The horizontal axis of this large circle, or wheel, as we have defcribed it, is formed of a double cone, which is hollow throughout, and has pivots of hard fteel at the extreme ends; it has four fupports, from an idea that the weight would be too much for the pivots alone to bear. One of the fupports is feen at D D, which is a kind of frame attached to the perpendicular pillars C C next to the eye; the extreme end of the axis *a*, which is not perforated, bears on a Y formed in the middle of the crofs bar of this frame, which bar has an adjuftable motion up and down, by means of the fcrew *p*, with a head divided into 50 parts, each of which parts correfponds to $\frac{3}{150}$ of an inch. Another fupport, every way fimilar to D D, is attached to the two upright pillars C C, behind the circle, which therefore cannot be feen, but requires no further defcription. The third and fourth fupports of the axis are a fifth pillar, the top of which is feen through the arch of the frame D D and its bottom near G, and a fixth pillar, P, oppofite to the former. Thefe two pillars placed nearer the middle of the ftage A, than the four corner pillars, C C C C, are each three feet and three inches high, and eleven inches diftant from each other, meafured from the interior fides we prefume; they are made fteady at their fuperior ends, each by two crofs-bracing pieces, *t t*, faftened to the long pillars, C C and C C, refpectively; one of which pieces *t* only can be feen attached to the right hand fupporting pillar, owing to the pofition of the figure. On the top of pillar P may be feen a fmall frame, carrying a pair of friction rollers; which frame can be lowered or raifed by a rod paffing through the pillar down to below the ftage A, under which is hid from the fight a fcrew of adjuftment for the height of the faid rod and frame of friction rollers. The rollers are placed edge to edge in the fame plane, forming a kind of curved V between them, on which the projecting ring of the conical axis is fupported. The fituation of this ring piece, attached to the cone, is at the mean point, between the centre of the circle and the back fteel pivot, which pivot is invifible in the figure. Thus one-half, or any fmaller part of the weight of the circle may be made to bear on this fupport, by adjufting the fcrew of the long rod within the pillar, the nut of which we have faid is under the ftage A. Another fupport, with a frame of two friction rollers, exactly fimilar to the one defcribed, is placed over the correfponding pillar, and under a correfponding annular piece embracing the fecond cone of the axis at its middle point; but the rod of this pillar, which adjufts the height and quantum of bearing of this fecond frame, does not defcend fo low as to the ftage A, but terminates a little below the middle of this pillar, which is cut into two and joined again by a fmall frame of four little pillars near I, fo that a hand may be put into the vacant fpace of the fmall frame, to adjuft by a tapped nut acting here, inftead of being put under the ftage A; the reafon of which is not quite evident from the appearance of the figure, nor is it explained in the original account. The end of the axis which is turned from view is perforated, and admits a lens that receives the light of a fmall lantern H, placed in a line with it, and tranfmits this light, without the entrance of fmoke or duft, to a diagonal mirror, that has got a central hole in it, placed at the point of interfection of the telefcope's line of fight, and of the central line of the circle's axis: this mirror again reflects the received light towards the eye-piece of the telefcope, and renders the two adjuftable hairs, which crofs one another at right angles in the united focus of the eye-glaffes, diftinctly vifible to the eye of an obferver on the darkeft night. It was found, however, that when much light was admitted into the telefcope, the ftars of fmall magnitude became invifible; on which account a contrivance was introduced for proportioning the quantity of light, according to circumftances. This contrivance confifts of a parallelopiped compofed of three pieces of glafs, the middle one white, and the two extreme ones green, contained in a frame which has an adjuftable motion by means of pullies, two of which may be feen on the infide of the back pillars, C C, which pullies affift the adjuftment during the time of making an obfervation, if neceffary, and limit the quantity of light, agreeably to the afcent and defcent of the parallelopiped interpofed between the lantern and the end of the axis. The reafon of the green glaffes being at both fides of the white glafs, is that the refraction of the light may be corrected by the fecond green glafs, fo as to prevent the wires in the focus of the eye-piece from appearing double. In this telefcope there are fix eye-pieces, five direct, and one diagonal, or what Piazzi calls prifmatic, becaufe the piece of glafs that is placed at the elbow of a bent tube, put on as an eye-piece, is a prifm bounded by one curved fide and two rectilinear ones, the latter two of which are placed at an angle of 45°, with refpect to each other;

other; the curved fide being that which firft received the rays of light, and the diagonal one, we prefume, filvered. The peculiarity of this prifmatic eye-piece is, that it inverts the object without reverfing it; that is, the pofition is changed with refpect to top and bottom, but not with refpect to right and left. The prifmatic eye-piece has two powers; one making the magnifying property of the telefcope 75, and the other 130. The powers with the five direct eye-pieces, are refpectively 50, 75, 100, 130, and 170. The principal ufe of the prifmatic powers is to fearch for ftars and meafure altitudes of bodies placed near the zenith; the faid eye-piece with its additional tube being horizontal when the telefcope is in a vertical pofition.

The vertical circle is graduated into 360° and figured into 90° four times over; each feparate degree is alfo figured with arabics, and the fubdivifions dotted or pointed like the azimuth circle. The obferved angle is read off by two different microfcopes with micrometers, placed above and below the vertical circle, at the diftance from each other of a femicircle; the frame E of the fuperior microfcope is attached to the neareft pillars, C, C, as fhewn in the figure, juft under the upper ftage B, which frame contains fliding pieces of adjuftment for fetting the microfcope in the required pofition with refpect to the divifions on the limb of the circle; the adjuftments both of the microfcope when placed, and alfo of its contained micrometer, are fimilar to thofe of the micrometer placed over the azimuth circle already defcribed. The inferior microfcope F I of the vertical circle is in every refpect fimilar to the fuperior one, the micrometer's divided nut in both being placed to the right. The micrometers of thefe microfcopes, however, have each two horizontal adjuftments of motion, one parallel to the plane of the vertical circle, and the other perpendicular to that plane, and alfo each a vertical adjuftment.

Befides thefe microfcopes for reading off the fubdivifions, each frame contains moreover a fmaller one, which we will call the fecondary microfcopes, the ufe of which is for viewing a fine plumb-line, fufpended by a fmall cock over the fuperior frame E, and paffing down to G through a wooden fquare pipe, where the plumb may be feen immerfed in the fmall veffel G full of water, above a fmall ftage *u*, in order to keep the line from ofcillating. This veffel G may be raifed or lowered by the fcrew that fupports it. The fecondary microfcopes have each the fame adjuftments as the above-mentioned microfcopes; and the plumb-line has alfo its point of fufpenfion fo adjuftable, that it can be brought into the foci of the upper and lower eye-pieces fo as to bifect the fields of view, when the microfcopes are both properly adjufted.

The plumb-line ferves two feparate, and both very important purpofes; its peculiar application to both which was another of Ramfden's happy thoughts; firft, it not only ferves to fet the vertical axis perpendicular in one pofition, but by being carried round in azimuth with the axis and all the other appendages, ferves to fhew if the perpendicular direction of the faid axis is preferved with refpect to all the points of eaft, weft, north, and fouth, and if any deviation is detected by the thread being at one fide of the original fituation, then one of the adjuftments of the iron circles, under the inferior pivot of the axis, as effected by the handle of the compound-joint under the mahogany ring M, muft be made to verify the pofition; and, fecondly, the horizontal axis of the vertical circle is made perfectly level by the fame plumb-line; this is effected by an additional apparatus, in a very ingenious, as well as very accurate manner, which may be thus explained without a figure: fuppofe a bar of metal to be made of fuch a length as, when ufed as a horizontal meafure, would juft reach from the divided face of the vertical circle to a point directly oppofite it in one of the pillars as the upper end; and fuppofe again this meafuring bar to be applied below to a point at the lower part of the faid pillar, to try if in this fituation it will alfo juft touch the graduated face of the fame circle; then, if the diftance is found to be precifely the fame in both cafes, the conclufion would be from fuch a rough meafure, that the pillar and the plane of the vertical circle are parallel, or very nearly parallel, to each other; now, as the circle was originally made by being turned on its own pivots in a large frame, its axis is neceffarily at right angles to its plane, and confequently alfo to the furface of the pillar; hence, if the pillar were perfectly perpendicular, the axis, on a fuppofition that the meafures were accurately taken, would be perfectly horizontal. But we know that a plumb-line is perpendicular whenever it is at reft, therefore any contrivance that will meafure very minutely the diftance from the plumb-line to the plane of the circle, both above and below, will determine whether or not the axis is horizontal; this contrivance is what we have to defcribe: conceive the faid bar of meafurement to terminate at one end after the manner of a two-pronged fork, and fuppofe one half of a compound-microfcope, *viz.* the object, object lens, and body of the inftrument, to be carried by one prong of the fork, and the eye-glafs in a feparate tube, borne by the other prong; and it is eafy to apprehend, that the image of any fmall object, whatever it may be, may, by the adjuftment of the object lens, be made to fall in the open fpace between the prongs, which image may again be rendered diftinct to the eye by the focal adjuftment of the eye-glafs; we have now got a meafuring-bar with a compound microfcope carried by it, in two feparate halves, fo that any fubftance, that will pafs between the prongs of its forked end, may be brought into the field of view, and be feen magnified by the eye-glafs, ufed on the principle of a fimple microfcope: let the thread of the plumb-line be this interpofed body, which, indeed, will cover only a fmall portion of the field of view; but as the plumb-line is not to be moved, except by the fcrew at the point of fufpenfion, nor even touched by any external object, the microfcope muft neceffarily be brought to it, and placed in fuch a manner, that the thread will bifect the field of view; this is done by fitting the forked end of the meafuring bar into the upper frame E firft, in fuch a way, that it may be made to flide in and out any number of times to the fame fituation; then the adjuftments of the frame, or of the cock of fufpenfion will bring the thread into the field of view; let now the object be a round dot on a flip of ivory, or mother-of-pearl would be better perhaps, and its image may be fo adjufted that the plumb-line will bifect it in its magnified ftate. This ingenious contrivance of producing an image in the open air has been denominated *Ramfden's ghoft* by fucceeding inftrument-makers from the name of its inventor. Let now the meafuring bar, which we will fuppofe to be too fhort, be laid, and fupported horizontally in a direction juft perpendicular to the plane of the circle, and let there be a thick pin fcrewed into its end next the circle, which, by being unfcrewed, will approach the plane of the circle till it juft touches it as the circle revolves, then the diftance from the extreme end of this pin to the plumb-line is exactly gauged; it is of no importance what may be the total length of this gauge, provided it be kept unaltered; remove, in the next place, the meafuring rod and its apparatus at each end in ftatu quo, to a fimilar fitting made for it in the inferior frame I F, and if, when the plumb-line bifects

the

the image of the dot here as before above, which the adjuſtments of the frame only muſt now effect, the pin at the oppoſite end turns out to touch the plane of the circle below at the ſame right angle that it did above, then the plane is perpendicular, and the axis neceſſarily horizontal; but if there is any deviation, the adjuſting ſcrew *p* on the bearing frame D D muſt rectify one-half of this deviation, and the pin which ſcrews into the meaſuring bar the other half; after a few trials above and below the horizontal poſition may be given to the axis in queſtion to the exactitude of a *ſingle ſecond*; for we have ſaid, that a microſcope may be depended on to that degree of accuracy in reading off a micrometer's ſcale. When the vertical circle is truly fixed, a ſecond meaſuring bar may be added at the lower frame while the firſt remains at the upper one, and then turning the circle round on its axis would ſhow both above and below when any alteration takes place in the true poſition from whatever cauſe. But inſtead of uſing the plane of the circle itſelf, Ramſden judged it better to fix a little bridge, *x y*, over the object glaſs of the teleſcope with a prominence *h*, which he made to come in contact with the pins of the meaſuring rod above and below ſucceſſively, by which means the contact is more nicely obſerved, and the method equally accurate. Whenever the line of collimation of the teleſcope is thus adjuſted, it will be certain to deſcribe a ſemi-circle in the heavens, when turned half round, which ſhall be truly perpendicular to the horizon, whether that ſemi-circle be in the meridian or in any given azimuth. Whenever Piazzi rectified the ſuperior and inferior micrometers and plumb-line, he took care to uſe the zeros of the vertical circle as the points that biſected the circle belt into two equal ſemi-circles; and he gives as a reaſon, that he found theſe did not deviate more than a quarter of a ſecond from their true places. When the vertical circle is uſed in taking altitudes, it may be clamped by a piece *k*, on the pillar P, which, when looſe, will allow a quick motion, but when faſt will only permit a very ſlow one by means of the handle V of the compound-joint, which, like that at Q, is connected with the tangent-ſcrew out of ſight. Theſe, we believe, are all the eſſential parts of the grand inſtrument before us, which we have thought it better to deſcribe in our own manner, than to make a ſervile tranſlation of the original, which muſt have been, as we have ſaid, not only too long, but imperfect without at leaſt three additional plates on a reduced ſcale.

It remains now, that we point out the advantages and diſadvantages peculiar to the conſtruction of the aſtronomical circle of Ramſden above deſcribed. Piazzi has enumerated eight advantages that his inſtrument poſſeſſes, as compared with a mural quadrant; which advantages may be claſſed thus: *viz.*

1. The graduated circles are not encumbered with verniers, ſo as to have its diviſions defaced, or its ſteadineſs moleſted.

2. The ſubdiviſions are read by microſcopes which magnify nine times, ſo that the leaſt quantity may be eſtimated.

3. The vertical circle has its plane made by revolving on its own axis, and alſo its circular lines ſtruck therefrom; conſequently both a deviation of the plane and eccentricity of the divided circles are avoided.

4. The compound circle preſerves its figure much better than it would have done if it had been caſt in one ſolid piece.

5. The obſervations may be reverſed with reſpect to both altitudes and azimuths; therefore a mean of two reverſed obſervations of an altitude will correct the ſimple errors of diviſion, and alſo the error of the croſs-hair or wire of the teleſcope, which, in one caſe, will be +, and in the other —.

6. The inſtrument may be placed in the meridian, and be uſed conveniently as a ſimple tranſit-inſtrument, when clamped to the baluſtrade.

7. It gives altitudes and azimuths at the ſame time; and therefore is particularly uſeful in ſingle obſervations of a comet, or other temporary phenomenon.

8. The refraction of the atmoſphere, correſponding to a given temperature, may be determined by calculation from an obſerved altitude and azimuth, taken at any hour, of any ſtar of a given declination.

We wiſh it had been in our power to have concluded this account by ſaying that we ſee no diſadvantage attending the conſtruction of the inſtrument before us, as it is a fabric of great ingenuity and labour; but a regard for the duty of juſtice, which we feel incumbent on us, obliges us to ſay, that one great objection to the conſtruction before us ſtruck us very forcibly at the firſt ſight of the inſtrument, which has been confirmed by profeſſor Piazzi's own candid account of its uſes: the objection, we allude to, is that which ariſes out of the manner in which the upper end of the vertical axis is ſupported; the pillars and ſurrounding arches of metal can ſeldom, if ever, be all kept at the ſame degree of temperature in ſo large an inſtrument, in any ſituation where it can be placed to be permanently uſeful in taking obſervations; conſequently, we were, in the firſt inſtance, led to fear, that the unequal expanſion of the warm and cold parts of the ſaid bearing-pieces would throw the vertical axis frequently out of its true perpendicular ſituation; accordingly we find, from the proprietor's own candid confeſſion, that obſervations of the ſun cannot be relied on, and that, even in obſervations of the ſtars, a new rectification uſually becomes neceſſary every hour that elapſes from the laſt rectification: when the ſun ſhines, there is alſo a difference in the two ſemi-circles of the vertical circle of 10″ or 12″ occaſioned by unequal expanſion: and the variation in perpendicularity is ſtated to amount to 4″ or even 5″ in the direction of a line from Eaſt to Weſt, in a ſingle hour; but in a direction at right angles to this line the error of deviation will not uſually be more than 2″. The greateſt error in ſimple graduations of the vertical circle does not exceed 3″; but in the azimuth circle there is an error of + 6″ in each of two quadrants, and a correſponding error of — 6″ in each of the other two, as determined by reverſed horizontal obſervations. Theſe laſt, however, are minor errors, compared with the liability of the vertical axis, to have frequent and conſiderable deviations from a true vertical poſition; which deviation muſt not only be very troubleſome to rectify every hour, but muſt ſometimes render an obſervation doubtful notwithſtanding every precaution.

Profeſſor Vince of Cambridge has given a ſketch and brief account of the principles of this inſtrument in his "Practical Aſtronomy," but has not given a detail of the parts of the inſtrument as it was actually conſtructed; he has alſo given a ſimilar deſcription of the principles of Ramſden's large inſtrument for meaſuring horizontal angles in the ſame work, which we propoſe to introduce under our article THEODOLITE, of which it may be conſidered as an improvement; and, in the mean time, thoſe readers, who wiſh to ſee an earlier account of it in detail, are reſpectfully referred to general Roy's account contained in vol. lxxx. p. 145, of the "Philoſophical Tranſactions of London," and alſo to the account of the "Trigonometrical Survey," publiſhed in 1799, by captain William Mudge, and Mr. Iſaac

Iſaac Dalby; in the latter of which publications all the neceſſary information may be obtained.

Repeating CIRCLE *of Chevalier de Borda, without Reflection.*

The happy idea of meaſuring the angle which two terreſtrial objects form, by repeating ſucceſſively the obſervations on all the parts of the circumference of a circle, we have already ſaid, is due to the celebrated Tobias Mayer; but there remained to contrive. conformably to this idea, an inſtrument calculated for geometrical operations, and which, if poſſible, might equally ſerve for aſtronomical obſervations. This was done about the year 1789, by chevalier de Borda, to whom geometry and navigation, as well as aſtronomy, owe many obligations. The circle of Borda has been executed chiefly by Lenoir, of Paris, and is uſually 19 inches in diameter; it is divided into 400 parts, according to the ſyſtem of diviſion adopted by the Academy of Sciences, on the 27th of February, 1793, and which has already been employed in the inſtruments of the ſame kind, which Mechain and Delambre uſed in 1792, and the following years, for meaſuring the arch of the terreſtrial meridian from Dunkirk to Barcelona. The axis of this circle which is fixed in the centre, and turned with the limb, carries two moveable teleſcopes, B, D, (*Plate* VI.) the one before and the other behind, which turn freely and independently of each other, quite round the circumference, on the axis of the circle itſelf, and which ſlide over its anterior and poſterior limbs. This axis is 10 inches long; it goes through a hollow cylinder A, which is fixed on the ſtand E F of the inſtrument: beyond this cylinder the axis bears a circular piece G of $5\frac{1}{4}$ inches diameter, indented all round to be moved by an endleſs ſcrew H, connected with the cylinder or ſocket on the ſtand; and which may be detached or made to act at pleaſure, in order that the whole inſtrument may be made to turn with a rapid motion, or move ſlowly by means of the ſcrew. Borda wiſhed to render this motion ſtill more gentle, by having the head of the endleſs ſcrew moved by another ſcrew.

The hollow cylinder A, which receives the axis of the circle, carries a weight K, $5\frac{1}{4}$ inches diameter, and $1\frac{1}{2}$ inch in thickneſs, to counterpoiſe the circle, in order that it may be placed ſteadily in an inclined poſition. It is this cylindrical piece which bears the ſcrew that catches the indented circle connected with the axis.

The front teleſcope B carries a croſs index piece which has four verniers, L, M, N, O, by means of which the diviſions are read in four points of the circumference; whereby Borda has done away the errors that reſult from the eccentricity of the inſtrument, and alſo thoſe of ſimple diviſion are diminiſhed. The back teleſcope D carries a level filled with pure ether and an air bubble; this level ſerves to place the circle in the ſame ſituation with regard to the zenith and horizon, whether the limb be eaſtward or weſtward; it is ſo ſenſible that the motion of one line ($\frac{1}{12}$ of a French inch) in the bubble makes only $7''\frac{1}{2}$ inclination, ſo that its ſituation may be aſcertained within 2 ſeconds. This back teleſcope alſo ſerves to take angles horizontally, by pointing it againſt one of the two terreſtrial objects, the diſtance of which is to be meaſured. The teleſcopes are 27 inches long, with an aperture of 23 (French) lines; they are achromatic made by Lerebours.

Each of the four verniers carries a magnifying glaſs to look at the diviſions, and a tangent ſcrew R to effect an exact contact; two of which verniers have beſides a clamping ſcrew each to fix the index to the limb, and an adjuſtment to bring the ſtar or other object to the thread of the teleſcope by a ſlow motion. The teleſcope that carries the level has alſo a lamp and an adjuſtment S to give it a ſlow motion, and to bring the bubble to the middle of its tube; an ivory ſcale divided along the bubble ſerves to bring it back to the ſame point. The reticule, a kind of micrometer in the eyepiece of the teleſcope, is inclined 45°, becauſe, in order to take angles on the ground, it is convenient to place the object within the angle of the two threads. Each teleſcope's reticule has a motion by means of a ſcrew, to make the line of collimation parallel to the plane of the inſtrument, which is done by the help of a proof teleſcope. The circle carries, moreover, a ſix-inch axis, parallel to its plane, at a diſtance of $3\frac{1}{2}$ inches, which axis is fixed acroſs the cylinder A, at right angles; laſtly, it carries a quadrant V, to ſtop it at any elevation, which quadrant turns within a frame E of ſix inches opening, into which the counterpoiſe K may paſs when the plane of the circle is placed horizontally. Parallel to the hollow cylinder A is a tranſverſe level X, five inches long, which ſerves to adjuſt the ſtand F and the limb of the circle to be exactly vertical. The frame E over the ſtand is at the top of a hollow vertical cylinder F, which is moveable round a vertical ſteel rod placed faſt within it, and exactly turned to the length of 18 inches. At the bottom of the hollow cylinder is an azimuth or horizontal circle Y, 10 inches diameter, divided into half degrees, with a vernier which gives the minutes. This circle is indented, and the vertical rod Z, which is within reach of the hand of the obſerver, terminates with a pinion *e* which catches the circumference, and makes it turn, moving at the ſame time the hollow cylinder that ſurrounds the axis, and ſupports the frame E, on which the circle is fixed. The three feet bear on bridges which are contrived to make the motion of the ſcrews inſenſible on the axis. The ſcrew *a* raiſes a bridge *a b*, that has its bearing point at *c*; but the ſcrew of the foot bears on *d*, and by turning the ſcrew *a*, the foot is made to move on the point *d*, which, being nearer to the bearing point *c* than the extremity *b* of the lever, receives and communicates to the circle a motion leſs than that of the ſcrew *a* and the bridge *a b*. By theſe ſmall triangles, Borda has hit upon the means of avoiding the jerks which are often produced in an inſtrument by turning the ſcrew of the ſtand.

In uſing this circle for aſtronomical obſervations, the axis of the inſtrument muſt firſt be placed in a poſition nearly horizontal, by means of the ſmall quadrant V, that ſerves to incline the plane of the circle; then by uſing the ſcrews of the ſtand, ſuch a ſituation may be given to the inſtrument, that, when it makes a whole revolution round the vertical axis, the bubble of the level P will continue nearly in the middle of its tube. This precaution is very important, for it was found that 15 minutes of inclination in the plane would produce an error of two ſeconds on the inferior altitude of the pole ſtar; and that 33′ in the inclination would produce 10″; when the caſe happened, it was with ſome difficulty, that the cauſe of this diſcordance was found out. This level muſt alſo be verified by the addition of a plumb-line ſuſpended over the limb. The obſervations are always made by pairs, the one on the right of the inſtrument, and the other on the left; we ſhall therefore deſcribe them by pairs of obſervations.

Firſt obſervation of the pair.—Bring the vernier of the teleſcope B to zero of the limb and fix it faſt with the clamp; then move the whole circle by diſengaging it from the endleſs ſcrew, until the teleſcope points nearly to the ſtar obſerved; then the ſcrew H being made to catch the teeth, either this ſcrew or that of the ſtand of the inſtrument muſt be uſed to keep the thread of the teleſcope conſtantly on the ſtar obſerved; in the mean time the teleſcope D of the level behind the inſtrument is brought back to a horizontal poſition,

ſition, until the bubble be in the middle of the tube, which is done by uſing the adjuſtment ſcrew of the teleſcope; the level X is next brought back to the poſition it ought to have by means of the ſcrews of the ſtand of the inſtrument; and, laſtly, when the two levels, that of the teleſcope and that of the axis, are rightly placed, and the teleſcope is at the ſame time directed to the ſtar, the firſt obſervation is gone through.

Second obſervation.—To complete the ſecond obſervation of this pair, the inſtrument muſt be made firſt to revolve quite round its vertical axis, and the teleſcope being brought back on the ſtar, muſt be fixed by means of its fixing ſcrew, then the adjuſtment ſcrew muſt be uſed to keep it conſtantly directed to the ſtar; in the mean time the inſtrument is levelled, either with the ſcrews of the ſtand, or with the ſcrew H, to give the two levels the ſame poſition as they had before the firſt obſervation; but it is to be obſerved, that it is not neceſſary to uſe the ſame ſcrupulouſneſs for the ſmall level X, unleſs obſervations are made near to the zenith, for at a diſtance of 43° from the zenith, an error of 7 or 8 minutes in the poſition of the bubble produces only half a ſecond in the meaſured angle; but the level of the teleſcope muſt be placed as exactly as poſſible in the ſame poſition as it had originally, which will be eaſily obtained by means of the bridge *a b*; this level being thus exactly adjuſted, and its teleſcope being properly directed on the ſtar, the ſecond obſervation of the pair is gone through, and in this ſituation the vernier of the teleſcope will mark a quantity juſt double the angle required to be meaſured.

Firſt obſervation of the *ſecond* pair.—If a ſtill greater preciſion is wanted, a ſecond pair of obſervations are thus uſed; the inſtrument is brought back to its former ſituation, and the limb to the weſt; the endleſs ſcrew is detached; the whole circle is turned, and the teleſcope is again directed to the ſtar. The level is then made to turn, and the bubble brought to the middle with the adjuſtment ſcrew of the level alone, without touching the circle.

Second obſervation of the *ſecond* pair.—The circle being turned back again from weſt to eaſt, as in the ſecond obſervation of the firſt pair, the level muſt be adjuſted, and the bubble brought again to the middle by the motion of one of the feet ſcrews, or by the endleſs ſcrew H; after which the teleſcope is brought again to the ſtar, by making it paſs through double the zenith diſtance, as in the ſecond obſervation of the firſt pair; in this ſituation the vernier ſhews four times the diſtance, ſeeing that it began ſecondly at that point of the limb where the index was after the firſt pair of obſervations, in like manner as it began from zero in the firſt inſtance.

After the firſt pair of obſervations, which have given double the true zenith diſtance, are completed, the level muſt always be placed again preciſely as it was at firſt, which attention is very important when the obſervation is to be connected by a continued multiplication; for if the level ſhould be put 2″ differently, a diſtance from the zenith will be found, that being doubled, will make this ſimple error amount to 4″ more or leſs than it ought to do, ſo that the exactneſs ariſing out of the multiplication of the angle, which is the great advantage of the circle, will be counteracted.

A third pair of obſervations may be thus made, and ſix times the angle obtained, and ſo on for any number of pairs.

By this method of obſerving the angle, the error ariſing from the diviſions will continually decreaſe, and it may be conſidered as nearly annihilated after a certain number of obſervations. Six obſervations on the ſtars that revolve the moſt rapidly, may be made before they come to the meridian to the ſouth, and ſix after; and as the error in each is not 10″, the reſult may be depended upon to 1″ nearly. An expert obſerver will only want one minute and a quarter for each obſervation, ſuppoſing one perſon to be at hand to place the level, and another to note the ſecond. With the pole ſtar 48 obſervations may be made in one hour, and in one revolution the meridian altitude of this ſtar may be obtained within the accuracy of half a ſecond. For this purpoſe it is neceſſary, every time that the ſtar has been brought to the thread, to count the minute and ſeconds, to obtain its diſtance from the meridian, in order to get an account of the reduction; but it is not neceſſary to apply each reduction to the zenith diſtance which has been obſerved; it is even uſeleſs to note this diſtance, the laſt, that is, the ſum of all the preceding ones, is ſufficient.

To render this operation more intelligible, let us conſider the two firſt obſervations on the ſtar made in the two ſituations of the circle; they would give double the zenith diſtance if the ſtar had not changed; but let us ſuppoſe that one minute has elapſed between the two obſervations, and that the ſtar has aſcended 10″ during that minute; inſtead of double the zenith diſtance that would be obtained if the ſtar had not changed, we have the ſum of two diſtances, the ſecond of which is ſmaller than the firſt by 10″, if they were calculated ſeparately; the ſum found ſhould be divided into two parts, the one of which would exceed the other by 10″, and the two zenith diſtances for the two moments of obſervation would be obtained; it would beſides be eaſy to refer them immediately to the meridian.

For inſtance, let us ſuppoſe that at the moment of the firſt obſervation, we find, either by calculation, or by a table ſuch as Borda's, that the ſtar was 50″ lower than in the meridian, and in the ſecond obſervation only 40″, the ſtar having aſcended 10″ in the interval; 90″ ſhould be added to the obſerved ſum of the two zenith diſtances, this ſum ſhould be divided into two equal parts, and double the zenith diſtance in the meridian itſelf would be had; for we had two parts, the one of which was 10″ greater than the other; but 40″ were to be added to the former, and 50″ to the latter, to make them equal, hence 90″ have been added to their ſum, therefore they are equal, and half their ſum gives the diſtance ſought for, that is to ſay, the zenith diſtance in the meridian; but it is more eaſy to pay no regard to this change of altitude till after ten obſervations, or even more, are finiſhed.

When we have ten obſervations, and we take the tenth part of the amount of the degrees, we have the diſtance from the zenith, but this total is too conſiderable by ten reductions to the meridian, ſince this zenith diſtance, which is not taken in the meridian itſelf, is too conſiderable; we muſt then calculate each of thoſe reductions, and take the tenth part of their ſum, to be ſubtracted from the tenth part of the obſerved degrees, which is the ſame as if we had ſubtracted from each of the zenith diſtances the reduction belonging to itſelf.

When we take another ſeries of ten ſubſequent obſervations, we find nearly the ſame ſum; they only differ becauſe the ſum of the reductions is not the ſame as in the firſt ſet of ten.

In order to calculate the reduction of the different obſervations to the meridian, when this ſyſtem of repeating is uſed, general tables, ſuch as are contained in Caſſini's book, will be found uſeful; where an example of thoſe calculations is given at full length: there is alſo in the French "Connoiſſance des Tems," a table of reduction for the pole ſtar in particular, which is carried to 45′ from the meridian, calculated by C. Borda, the inventor of the inſtrument we have been deſcribing.

The

The repeating Circle *without reflection, as made by Troughton.*

Plate VII. exhibits the repeating circle for measuring celestial and terrestrial angles, as it has been constructed in London, on a scale of magnitude where the vertical circle is of 18 inches diameter: the construction differs in many respects from that of the instrument made in France, from the directions of Borda, and as we conceive it may be considered as an improved instrument, we think it will be rendering astronomers and surveyors an acceptable service to describe it in this place, by way of contrast with the preceding one.

Fig. 1 represents a general view of this instrument, and *fig.* 2 has the circle, index, telescopes, level, &c. detached, in order to shew more distinctly some of the smaller parts. The great letters refer to the general view, the small ones to the partial one.

The circle, A A A, consists of eight conical tubes joined to an octagonal centre piece at one end, and the strong circular border at the other: this circular limb is strengthened by another in the form of a hoop, which forms an edge bar thereto. The circle is divided into degrees and every 10′. The index B has the usual contrivance for fast and slow motion, and consists of four branches, each of which is furnished with a vernier that subdivides the limb to 10″. C is the front telescope, 25 inches long, placed at half right angles with the branches of the index, to which it is fastened near the centre; but in order that it should obey the motion of the axis alone, it has no connection whatever with the limb. The axis of this index and telescope occupies the whole length from *a* to *a*. On the back of the circle is another index D, the single branch of which carries the apparatus for fast and flow motion, and clamps to the edge bar portion of the limb, to which it is contiguous. The back telescope E, similar in every respect to the other, is fixed near the centre to this index, and as near as possible to the axis, and below it: the spirit level F is also fastened to the same index above the axis, where it forms a counterpoise to the telescope; they all revolve together round the axis of the circle on a socket, with a length of bearing equal to *b b*. The general motion, where the circle, indices, telescopes, and level, all turn round together, is formed at the posterior part of the axis of the circle, which fits the socket that crosses the horizontal axis *c*, in a bearing reaching from *c* to *d*; *e* is the flaunch of the axis on which the front telescope turns; *f* is that by which the circle is fixed to its hollow axis; the part *g* passes through the octagonal centre piece, and *h* is the flaunch of the back index. G is the counterpoise fixed upon the socket of the general motion, whereby the whole is balanced on the horizontal axis. A clamp *i* in three pieces, jointed like a watch chain, embraces a collar on the hollow axis of the circle, and is acted on by the screw *j*, by which the general motion may be clamped at pleasure. To the upper part of the clamp is fixed a cock *k*, and to the upper part of the horizontal axis is fixed a cock *l*; these two cocks are connected by a screw *m*, which, when *j* is clamped, gives slow motion to the circle, telescopes, &c. but when *j* is loose, allows a free motion.

Two microscopes appear, in the general view, looking at two opposite verniers of the index; by an easy motion round the centre, these may be turned to read off also at the other two verniers. By the semi-circle *n n n*, which is fast to the horizontal axis *o o*, the circle may be made fast in any position respecting its motion round this axis; this is done by a clamp at the lower end of one of the supporters, opposite to its fellow supporter H; on this semi-circle are three divisions, which correctly mark its two quadrants; the circle being brought into the horizontal position by means of a nice spirit level applied to its surface, and an index adjusted to the middle line, the extreme lines will shew when the plane is vertical on either side the pillar.

The azimuth motion of this instrument is formed by the pillar turning round a strong steel axis, which is fixed in the tripod, and reaches up to the top. The circle is 12 inches diameter, turns with the pillar, and is divided like the other circle; three verniers, which subdivide it to 10″, are fixed to the tripod, which, with many other parts, are too plainly exhibited in the figure to need a particular account in words.

With Borda's repeating circle without reflection, as formerly constructed, it was nearly impossible to observe bright stars and planets by day, and small stars also, because not easily distinguished one from another in the night time. To remedy this, Mr. Behrnauer of Budissin, an ingenious amateur of astronomy, proposed to Troughton, a few years since, an apparatus for stopping the telescope and level at their relative positions, similar, in some respects, to what he had before successfully applied for stopping the indices of Borda's reflecting circle. The apparatus consists of a divided semi-circle, attached to the back index, having two sliding stops, which, being set to the proper zenith distance of an object to be observed, will be touched alternately in the reverse positions by a pointer annexed to the front telescope. In the figure this semi-circle is seen at I, near which letter, one of the stopping sliders rests at about 30° of zenith distance; the pointer J is in contact with the other slider. This having fully answered the purpose, Troughton thought it would be almost equally desirable that the azimuth motion should have its stops also. For this end a small cylinder, with an obtuse point, is inclosed in a tube, which, pushed forwards by a spiral spring, enters alternately a couple of holes made opposite to each other in the edge of the azimuth circle, at 360° and 180°, and thereby produces a stop, which may be felt when the face of the vertical circle is east or west, but withdraws from the holes with a small force, and allows the instrument to turn. By these simple contrivances, the object to be observed will always be found in the field of view, without the trouble of having recourse to the divisions.

This may be regarded as a considerable improvement, not only because the bright stars may be observed by day, and faint ones by night, but also because the business of repeating or multiplying the angle will be facilitated thereby; and consequently the astronomer enabled to make a sufficient number of observations proportionally nearer the meridian.

Lastly, it may be remarked that in England there exists an ungenerous prejudice against this instrument; while on the neighbouring continent, perhaps, its value may be too much extolled. It is certain, however, that while the trigonometrical operations, between Paris and Dunkirk, for ascertaining the distance between the national observatories of England and France, or the more recent and extensive measurements of the same nature in the south of France and in Spain shall remain upon record, the repeating land circle of Borda will be estimated among the very first instruments, for the general purposes of astronomy and topography, with every one who is in the least acquainted with these subjects; to which we may add, as our concluding remark, that the alterations and additions made in this instrument by Troughton have greatly contributed to its improvement, whether we regard the accuracy or facility of its operations.

Circle, *by the Rev. Francis Wollaston, LL.B. and F.R.S.*

In a paper read before the Royal Society of London

don on May 9, 1793, and publifhed in the "Philofophical Tranfactions," Dr. Wollafton has given an account of a *tranf't circle*, which he contrived, by the affiftance of Mr. Ramfden and Mr. John Smeaton, and which was made by Mr. W. Cary of the Strand, after Mr. Ramfden and Mr. Edward Troughton had declined undertaking the conftruction under the doctor's fuperintendance. The undertaking originated from an impreffion, that an inftrument, which would at the fame time determine with precifion both the right afcenfion and declination of a heavenly object was, notwithftanding Ramfden's aftronomical circle, a defideratum in aftronomy, and though the doctor at firft intended only to fuggeft to fome one of the beft inftrument-makers the notion he had entertained of an inftrument of extenfive application in afcertaining the relative fituations of the heavenly bodies, yet, on finding that his plan was not likely to be readily adopted, he fet about the bufinefs at his own expence, and, fortunately, met with a maker whofe merit did ample juftice to the defign, notwithftanding the obftacles that occurred to impede his progrefs in the different ftages of an original conftruction. It will not be neceffary for us to accompany the doctor through all his narrative of difappointments and reafonings contained in his paper, but to felect thofe portions principally that relate to the defcription of his inftrument; which office we propofe to do in his own words, as nearly as our mode of arrangement will admit.

"The drawing accompanying this account (in *Plate* VIII. of *Aftronomical Inftruments*), will fhew the general form of the inftrument; and needs very little explanation. The whole ftands on three feet, adjuftable by fcrews, on a cylinder of one folid ftone of $25\frac{1}{2}$ inches diameter and three feet fix inches long, bedded on a pier of brick, well bonded together, and rifing from a good foundation, deep in the earth. The bottom plate, of $21\frac{3}{4}$ inches diameter, turns in azimuth, not on a long axis, but on a centre; and rides on a bell-metal circle, truly turned, and to which the bottom plate itfelf is ground. In this way it moves very fmooth by hand; but it is capable of being turned by a winch, with tooth and pinion. The intent of its turning thus is merely for the convenience of reverfing the inftrument: for, though it might be ufed out of the meridian, and for azimuths, yet, fince it is defigned principally for meridian paffages, when it is in its place the whole is clamped firmly to the bottom frame by four clamps, which confine it to the circle on which it rides: and this method of turning proves itfelf to be fteady, by the levels on the bottom plate never altering in the leaft upon fcrewing the clamps.

"The four pillars, and their braces, explain themfelves. They ftand over the bell-metal circle; and the clamps are placed near the foot of each for greater fteadinefs; fince they carry the Ys for the pivot of the tranfit.

"The conftruction of thefe Ys is peculiar: they hang, as it were, in gimmals, or gimbols, though of a very firm kind, and have a horizontal motion, fmooth and fteady: the T, or frame which carries them, turning on a perpendicular axis of $2\frac{1}{2}$ inches ground to its focket, on the outfide of the plate which connects them with the pillars, and refting on that plate to which the bottom of the frame itfelf is ground likewife. In this frame they have a vertical motion: the Ys themfelves carrying a horizontal axis, which, confifting of two frufta of cones on each fide, in contrary directions, with a collar over them, guards againft any fhake whatfoever, while it admits of the Y adapting itfelf to the direction of the pivot. The idea of hanging them in this way, as well as that of turning the whole inftrument in azimuth on a ground plate, was fuggefted by Mr. John Smeaton; to whom the world has been indebted for repeated capital improvements in mechanics.

"By thus hanging the Ys, the pivots have a bearing on them from end to end; inftead of riding on a bell-metal ridge, as is the ufual method where the Ys are fixed, and cannot fet themfelves in the direction of the axis. This feems to be a better bearing, and much lefs likely to wear the pivots.

"Yet, to guard againft any wear, a pair of cylindrical fprings, included in a tube, are applied through rings within the connecting plate above mentioned. Thefe carry, each of them, a pair of rollers, on which a brafs collar on each end of the axis of the telefcope rides. The fprings may be ufed or removed at pleafure; and they can be ftrengthened or weakened, by means of a fcrew at the bottom of the tube, fo as to take off from the pivots any part of the weight that may be judged beft: and, fince they are in a line with the axis, and are made capable of obeying it in every direction, there is no danger of their deranging its adjuftments, while they render its motion exceedingly light and fmooth indeed.

"The adjuftments of the Ys are both of them at the fame end of the axis, oppofite to the divided circle and the microfcopes; becaufe the fmalleft adjuftment of that end of the axis between the microfcopes would have affected them fo as to require an entire re-adjuftment of them too. At the farther end the axis is perforated, to admit light for illuminating the wires. The axis itfelf is 18 inches long, exclufive of the pivots, which are about $1\frac{1}{4}$ each.

"The microfcopes need no defcription. They are on the fame principle as thofe in Ramfden's inftrument, which are more fully defcribed by major-general Roy, (Phil. Tranf. vol. lxxx. p. 145.) and in captain Mudge's account of the "Trigonometrical Survey," vol. i. Lond. 1799. Mine are 9 inches long; the object-end at 2 inches from the limb of the circle. They magnify 24 times. One revolution of the micrometer-fcrew is equal to one minute; and the head is divided to feconds.

"The fixed, or ftationary wire in them, is at the firft notch, or minute itfelf; and it is adjufted by means of a plumb-line, which hangs from the top plate, and paffes by the fide of the axis; at about 8 degrees, from the centre. For this purpofe, there are dots made on the limb, at a fuitable diftance on each fide of the zero, both above and below, whether the telefcope be horizontal or perpendicular either way. Thefe are viewed through two compound microfcopes, (of $5\frac{1}{2}$ inches long, and their object-glafs at 3 inches diftance from the limb) carried by the fame frames as the other microfcopes.

"The curfor, or moveable wire, in the micrometer-microfcopes, is adjufted much in the fame way as general Roy's; excepting that the micrometer head is made to turn ftiffly on the neck of the fcrew, fo as to allow of bringing the point of zero to front the eye, without the trouble of re-adjuftment, if it happened to fall behind.

"There is, of courfe, a very fenfible level for adjufting the axis. The circle was ordered to have ten radii; that when the telefcope is horizontal, and pointing to a meridian mark, there might be a vacancy between the cones, above or below, for introducing a level. In the brace between the pillars, over the moveable Y, (at A), it may be obferved, the bottom bar is omitted, in order to give the better room for paffing the level, without inclining it, or running any hazard of ftriking it. From the lower bar of the oppofite brace B, over the fixed Y, there ftands out a forked piece of brafs, to receive the leg of the level, and direct it to its place;

place; as alfo for keeping it upright when the foot ftands on the pivot, and juft allowing a very little fhake, fo as not to cramp it. By this contrivance the level is eafily handled, and reverfed without danger of difturbing it or the inftrument.

"The top plate, as may be feen in the drawing, has a large opening cut more than half way acrofs it. The defign of this is, to allow you to obferve quite up to the zenith, and a little beyond it, clear of all obftruction whatfoever. And fince the whole inftrument is capable of being reverfed, or turned half way round in azimuth; when you have occafion to obferve the tranfit of the ftars, in that part of the heavens where they would be intercepted by the plate in one pofition, it is entirely out of the way in the other.

"The circle itfelf is of full two feet diameter at the divifions; being $25\frac{1}{2}$ inches at the edge. The undivided circle, on the fide of the telefcope next to the open end of the axis, ferves for ftrength and uniformity; and to it is applied the clamp of elevation. That clamp is fo made, as to allow the circle to run freely all round, not bearing at all againft it, but fupporting itfelf, and yet being eafily removeable. It has no command over the circle whatever, when handled with care, excepting in the altitude of the telefcope, by an adjufting fcrew when the clamp is fet: and, as that fcrew has a milled head at each end, it is as conveniently turned from the one as from the other fide of the inftrument, to bring the horizontal wire to bifect the object.

"The telefcope is of 2 inches aperture, and 33 focal length. The object glafs does not flide within the tube, but fcrews into the end of a piece of falfe tube, of 4 inches length, which flides on the outfide of the principal tube, and is fixed in its place by 3 fcrews and collars running in grooves, when its diftance from the wires is adjufted.

"In this way one has the whole aperture of the tube, and no greater length than is abfolutely neceffary for ufe, which, in fuch an inftrument, appeared to be an advantage. In fome refpects it is fo; yet the hazard of difturbing the collimation by touching the outfide of the tube is an objection.

"The wires are not in one cell, but in two diftinct cells, with their faces towards each other. The perpendicular wires are 5, at 35 feconds of time diftance in the equator, and are adjuftable horizontally for collimation by a fcrew. The horizontal wires are 3, at about 15 minutes of a degree afunder, placed fo as juft not to touch, but to pafs clear of the other wires; and they are adjuftable in collimation by another fcrew peculiar to them. The two cells have each a power of turning feparately on the axis of vifion; but when once the two fets of wires are brought to be truly at right angles to each other, the cells can then be fixed together, and turned together, and finally fettled in their place by fcrews and collars at the outfide of the tube. Thefe things, I believe (fays the Doctor) are new; I thought they might be improvements on the ufual method; yet I find the adjuftment of the horizontal wires in collimation might be difpenfed with.

"My reafon for having three horizontal wires, and at about that diftance, was, that after having afcertained what the difference is, I might obferve the lower limb of the fun or moon at the one, and the upper limb at the other of the extreme wires, without much altering the elevation of the telefcope, and removing the centre of the object, or preceding and fubfequent limbs of the fun and moon, far out of the centre of the field.

"The divifions on the circle itfelf come now to be fpoken of. They were done by hand, and have been executed with great care. The original divifions are by dots, or points, at every ten minutes. Within is another row, by ftrokes or cuts, laid off from the points to every ten minutes likewife. The dots are what we will regard firft, the cuts afterwards.

"As it always appears to me convenient, in actual obfervation, to contrive that every thing fhall do itfelf, as far as I can, and to leave the mind as well as the body at perfect eafe, and totally difengaged from calculation, I confidered that making both the microfcopes talk the fame language, read off the fame way, with the guiding figure always to the fame hand, and the dot to be obferved to the fame hand too, and the readings always pofitive, would conduce much to one's eafe, and thereby very greatly indeed to the accuracy and certainty of the obfervation.

"With this intent, fince the microfcopes are, the one above, I ordered that to be marked A; the other below, B; confidering that the numbers deduced from them could never be miftaken, if one got into the habit of examining A firft, and noting that down, and then examining and fetting B under it; which, if all things are true, ought to be the complement to 90 degrees.

"To make the reading pleafant, I ordered the micrometer-fcrew in each to be placed on the right hand, and confidered the moveable wire as always to be kept to the right hand of the other. This will, of courfe, in all cafes meafure the diftance of the fixed wire from the neareft dot apparently on the right, or, fince the microfcopes invert, the neareft dot really to the left, which will be either the degree itfelf on that hand, or fome multiple of ten minutes from it.

"That the numbering of the degrees might coincide with this idea, I confidered that the figures fhould be made to appear erect in the microfcopes in every pofition of the telefcope, which they might be whenever it does not point below the horizon, and that they fhould be reckoned backwards. To effect this, they ought to be reckoned backwards in themfelves, but to ftand the contrary way, or inverted in reality. This would be different in the two microfcopes in refpect of the centre of the circle, but that could create no difficulty. For, fince the two quadrants neareft to the object-end of the telefcope would always be thofe coming under the examination of microfcope A, and the two neareft to the eye-end, thofe to be obferved at microfcope B, they might be figured accordingly. Hence, fuppofing the inftrument placed in the meridian, with the graduated face turned towards the eaft; if, when the telefcope is horizontal, and points to the fouth, the upper quadrant neareft to the object-end be numbered from that end from 1 to 90°, with the head of the figures towards the centre of the inftrument, and the other upper quadrant be numbered from the eye-end, with the feet of the figures towards the centre, they both would give the zenith-diftances of the objects obferved. The former at microfcope A, while the telefcope points to the fouth of the zenith; the latter at microfcope B, when you are obferving towards the north.

"The two other, or lower quadrants, follow a fimilar rule, and ferve to fhew the altitudes, if both be numbered from the quadrature, inftead of either end of the telefcope; thofe leading towards the object-end being placed with their heads, while thofe towards the eye-end ftand with their feet towards the centre of the circle.

"The inftrument has a figure at every degree, that one may always be in the field of view of the microfcope. Hereby it may be feen, that all on one fide of the telefcope give zenith diftances, while all on the other fide give altitudes; and yet, that the figures in both the quadrants neareft to the object-end are placed with their heads towards the centre, and all towards the eye-end with their feet. This became neceffary; and though it was a little perplexing at firft to contrive

trive and see executed properly, it is found very convenient indeed in use.

"The interior divisions, or cuts, are also numbered at every degree each way, from the eye-end to the object end of the telescope, with the feet of the figures always towards the centre. The use of them is likewise very great, not for reading off the observations, but for setting the instrument. For, at a proper distance from the main pillars, there is a small pillar, carrying a compound microscope with a wire in its focus, which being adjustable, and once set to the latitude of the place, gives immediately the north polar distance of any object seen; or, by fixing the instrument according to the polar distance of an object sought, one is certain of its entering at the proper time the field of the telescope, near the centre wire. This pillar for the polar microscope is removable to the other side of the main pillars, which becomes necessary when the instrument is reversed.

"This in general is the form, and these are the peculiarities in the construction of this instrument, which being designed for meridian observations, or transits, I apprehend may best be named a *transit circle*.

"In observing, I always study to be as much at my ease as possible, and therefore I always sit, and use a prismatic eye-glass. To avoid touching the instrument itself, or even the stone on which it stands, I have four upright poles from the floor to the roof, with cross-braces on a level with the bottom plate of the instrument, against which I may lean while I observe, or when I handle any part of the instrument. These I find to be of great comfort and use. Against two of the poles I hang a curtain occasionally to keep off the sun, or to lessen a false light when I observe a star in the day.

"The two exterior horizontal wires, mentioned above, I find very convenient. They are really 14′, 43″, 5 of a great circle distant from the centre. By means of them I can without any hurry observe the preceding limb of the sun at 3 wires; I set the lower limb to the upper wire, and read that off; then the upper limb to the lower wire; and am ready to observe the second limb of the sun at the 3d, 4th, and 5th wires; and lastly I read off the upper limb after the observation is ended. In this way one has the meridian passage through the middle of the field, or within 2′ of it; and the meridian altitude of both the limbs, while the sun's centre is on the meridian; for the little alteration in altitude is soon done, and can disturb nothing.

"Indeed, upon the whole, this instrument itself is capable of doing a great deal of good work, and convinces me fully that one between piers would be highly advantageous to astronomy. As a transit, mine is perfect, so far as that size permits: indeed it is in fact to all intents a transit-instrument. And for altitudes, since the readings are totally independent of the circle, though you have it in your power to re-examine your microscopes by the plumb-line between each observation, if you please, you find there is no occasion for it. In that respect it has the advantage over a quadrant. No force is used in setting this instrument; the whole, from its form, is counterpoised in itself; there is no more probability of deranging it in altitude, than in azimuth, and therefore all you have to do in actual observation beyond a common transit-instrument, is to bisect the star as it passes, or as soon as ever it has passed the meridian wire, and read off the microscopes afterwards. Thus every observation is complete, by ascertaining the right ascension and altitude of every object at once, and with very little trouble, which must tend greatly to the improvement of our catalogues.

"There is one additional advantage in an instrument of this form, that you have it in your power to reverse the whole in a few minutes without any hazard, which I do regularly; because thereby you discover and destroy any errors which there may be in the instrument itself, or which may at any time arise in observing."

Portable Circular Instrument for Transits, Altitudes, and Azimuths, by Troughton.

About the year 1790 the portable astronomical quadrant began to give place to the circular instrument; previously to that year, indeed, a few circles had been made for the sole purpose of observing altitudes, but their improved state cannot be dated farther back than the time we have mentioned.

The instrument, represented in *Plate* IX. of *Astronomical Instruments*, is of the most improved kind: in the construction of which are combined the means of applying it to the various purposes of practical astronomy; namely, for observing right ascensions, declinations, azimuths, and equal altitudes; and also, to all the purposes of the most improved theodolite, and levelling instrument. It is contrived so that the joint effect injures not any particular part, but improves the strength and symmetry of the whole.

It has been made of different magnitudes, from one foot to three feet diameter; which dimensions are supposed to be the boundaries of this construction. Those of three feet, however, can hardly be called portable: fifteen and eighteen inch ones are the sizes usually made: the one under consideration partakes of both, the lower circle being fifteen, the upper one eighteen inches diameter.

This being designed for a traveling instrument, its own packing-box is intended for a pedestal, where a better cannot be procured, and may do well enough when the purposes of surveying, &c. require its presence in the field; but in the observatory it ought to be mounted upon a firm stone.

The base of this instrument is a strong tripod supported on feet screws, two only of which are seen in the figure A and B. To the centre of the tripod is fixed the axis of the azimuth motion, about sixteen inches long: in close contact with the tripod is the azimuth circle C, which is one entire plate; it is nicely centered upon the vertical axis, but only capable of being turned round through an angle of about three degrees; and for that purpose is acted on by a slow moving screw, the head of which is seen below, a little to the left of the centre. The use of this motion is for setting the telescope to the meridian, when the index of the proper azimuth motion has been previously set to zero; or it is for adjusting the instrument to the point of commencement, when horizontal angles are measured. A telescope is affixed to the lower side of the tripod having universal motion, which being set to any object, becomes a sentinel for watching the position of the instrument, and pointing out any deviation that may happen to take place during the time required in any operation. The index of the azimuth circle is also one entire plate D, having, for the sake of strength and lightness, an half contrate edge one inch deep: the middle cone E is attached to this, and centered upon the vertical axis by two inside collars nicely fitted thereto: this forms the azimuth motion, the weight resting on the centre at the lower end. The tangent screw is fastened to the index plate, and goes round with it when quick motion is required. Two microscopes opposite to each other, one of which F appears in the figure, read off the azimuth, and subdivide the graduations of the limb. On the azimuth plate are also fixed the two strong pillars G G, which support the upper circle and remaining parts. A little below the top of the vertical axis is a strong bracing bar H, which, from its connection with the centre cone and two pillars, bind them firmly together,

gether, and prevent the incumbent weight from altering the figure of the attached plate. Higher up is seen the screw apparatus I, for procuring fast and slow motion for the vertical circle; this is fixed to the right hand pillar.

The vertical circle, K, is next to be noticed: it is composed of two entire circles, being flat plates crossed out into six radii, having each a circular border, and circular centre. The centres are perforated to receive the larger ends of the cones of the transit axis. The axis has a cylindrical part in the middle, equal to the distance of two circles; and this cylinder being terminated at each end by a flaunch L, the two circles are screwed fast to it, and here form the central pillar. The two circles are otherwise bound together along the radii, and round the limb, by a number of pillars placed perpendicularly between them. The side of the divisions is overlaid with another circular border, which covers the holes which the fixing pillars occasion; this ring used to be of fine brass for dividing upon, but recently one of the more perfect metals, gold, platina, or silver, has been used for that purpose. The telescope M is thirty inches long, and of two inches aperture; it passes through the cylindrical part of the axis, to which it is attached, and nearly fills the distance between the two circles, to which it is also fastened at their extreme borders. On the middle of the cones of the axis are soldered two rings S S, at a distance from each other, exactly equal to the distance between the two pillars. Two rollers at the top of the pillars are, by the force of springs, urged upwards against the rings so as to sustain the whole weight of the axis and circle, and thereby to relieve the parts of action from being injured by unnecessary pressure. The distance of the pillars being too short for the transit axis, its length of 16 inches is firmly supported by a bar N, screwed fast to each of the pillars, extending in a line with the axis, and is terminated by a Y, or angle, in which is secured the pivot or end of the axis: the bar is braced by a prop near the Y, which joins the pillars at a distance below. Two strong tubes O are firmly connected with the left hand pillar, with their ends bent upwards; these carry two opposite reading microscopes, R, R; they are finished with adjustments, P, P, for bringing them both upon a level; but the angles whereon the axis rests may be raised or depressed, so as to bring the horizontal diameter of the circle to suit their height; an adjustment by which also the level of the axis is effected. A spirit level Q Q is seen in the figure hanging upon the bent tubes, which, after having assisted in placing the vertical axis perpendicular, remains in its place, for marking any alteration of position that may happen in either the instrument or pedestal. This level may occasionally be removed to the telescope, and there helps to verify the position of the reading microscopes. Another level applies to the horizontal axis, just within the angles, resting thereon with two forks, and passing through between the bars of the circle: with this also the vertical axis may be adjusted, but its direct use is for levelling the one to which it applies. The instrument from which our sketch was taken has no plumb-line, although this size is sometimes furnished with that apparatus. However, it is rather doubtful whether the levels are not here quite as good; for the accuracy of the plumb-line increasing in proportion to its length, seems better adapted for large instruments than for the size before us; particularly, as levels may be used as good as in those of larger dimensions. The telescope has four eye-pieces, which give it different powers; one of which having a diagonal mirror affords a convenient view of the heavens about the zenith. T is a small support for the lantern which throws light into the end of the conical axis, and illuminates the wires of the eye-piece in the usual manner.

Respecting the powers of this instrument, it may be remarked, that the limbs of both circles are divided into degrees, and every five minutes; and that the microscopes of both sub-divide to single seconds; by which means an angle may certainly be read off to two seconds. The powers of the telescope are fully equal to this quantity, and shew the pole star in bright day light: the levels, which are furnished with graduated scales, are sensible to an inclination of one second, and the adjustments being few and simple are easily rectified, and not subject to derangement.

This circle seems better adapted for the use of the private observatory, or for a gentleman travelling, than the repeating circle of Borda without reflection; the latter being destitute of the properties of the transit instrument; whereas, this is a complete one. Besides, it is of a stronger frame, easier to manage, and equally portable.

We confess we cannot but admire the portable instrument we have here described, whether we consider its various properties, its stability, its accuracy, or its beauty of figure.

The mural Transit CIRCLE *by Troughton.*

In our account of the rise and progress of astronomical instruments in the first part of our present article CIRCLE, we had occasion to remark, that Romer was the first person who applied what he called a *reticulum*, which we have translated *reticule*, in the focus of a microscope as a measure of the divisions on the limb of an instrument; we also mentioned that Horrebow fixed a *circle* in the *meridian*, read off the divisions by microscopes before the year 1735; since which time there has been much conversation in England about substituting a mural circle for a mural quadrant in an observatory; and indeed various instruments, as we have seen, have been produced, to which a desire of rendering them as extensive as possible in their uses, has generally added an azimuth circle, which has proved detrimental to the requisite steadiness of a meridian instrument; but no instrument entirely answering the description of the title we have here given has been completed, at least in England, till so lately as March of the year 1806, when Troughton, whose mind seems to have been formed by nature for the very business that he is occupied in, delivered out of his hands a mural transit circle, which is contrived to give at the same instant both the right ascension and declination of any heavenly body, by the aid of a good astronomical clock, with a degree of accuracy that probably has never before been equalled. This instrument is in the possession of Stephen Groombridge, Esq. of Blackheath, to whom we beg leave to express our obligation for his obliging permission, granted to our draftsman, of taking the perspective drawing of his circle, which is contained in *Plate* X. of *Astronomical Instruments*.

This circle, which is four feet diameter, and formed principally of hollow cones, is framed upon a strong axis three feet in length; and consists of two complete circles, fastened together in a manner sufficiently explained by the figure. The telescope A, five feet long, and three inches and a half aperture, crosses the middle of the axis, and passes between the two circles, to the bodies of which it is attached. Each of the circles has a hoop, or edge-bar, at its back, to give it strength; and is further braced by many parts, which tend to unite the two together. There also passes through the axis another tube B at right angles to the telescope; this forms part of the plumb-line apparatus to be described hereafter. The axis is supported at its extreme ends on the top of two stone piers, about five feet four inches high; the pivots of the axis rest in angles, formed in brass-work, which is cemented to the tops of the stones. The angle at the end

end to the right is acted on by a ſcrew which gives it a very ſlow motion vertically, for the purpoſe of adjuſting the axis to be horizontal; and a ſimilar ſcrew at the left angle gives a ſimilar motion for bringing the plane of the circle into the meridian. The figure of the ſtone-piers is priſmatical, and their inner ſurfaces, 27 inches apart, are parallel and perpendicular. The circle is divided on both ſides into degrees and every 5′. Upon the ends of two ſtrong horizontal bars, D, D, are fixed four micrometer microſcopes, two on each ſide, exactly in the horizontal diameters of the circles: theſe, three of which appear in the figure, ſubdivide the diviſions of the limbs to ſingle ſeconds; and are the indices by which the value of the obſervations are read off. Another microſcope, at right angles to the former, is ſeen, which paſſes through the left pier, and, from its ſituation, is ſuppoſed to be ſteadier than the other parts. It is uſeful in examining the accuracy of the diviſions, and for detecting ſmall motions in the more expoſed parts of the inſtrument. Upon the axis, half-way between the centre and pivots, are ſoldered and turned two rings; immediately below there is cemented into the inner ſurfaces of the ſtones, an apparatus which, by means of a ſpiral ſpring, incloſed in a tube or barrel E, is made to puſh up a roller againſt thoſe rings, ſo as to ſuſtain almoſt the whole weight of the circle, and thereby to relieve the pivots of the axis and the angle from unneceſſary preſſure. This work is well expoſed to view on the left ſide, but partly concealed on the right-ſide by the intervening circle.

On the inner ſurface of the pier, to the right, is fixed a frame which ſupports the uſual apparatus for quick and ſlow motion, which the figure ſufficiently explains; this in the eaſt or weſt direction is extremely pliable; but in the direction of the meridian furniſhes a ſtout reſiſtance; it is eaſily got at, when the obſerver is looking to north or ſouth, and in thoſe caſes where the milled heads are out of his reach, a jointed handle aſſiſts him very conveniently. When the inſtrument is reverſed, this apparatus engages with the oppoſite limb. A ſmall ſtool is ſhewn in the figure between the two piers, below the centre of the inſtrument; on its top is repreſented the water veſſel for the plummet to ſwing in; this veſſel may be raiſed or depreſſed an inch or more by a rack and pinion, to ſuit the length of the plumb-line. The teleſcope, being turned round to the horizontal poſition, brings the plumb-line tube B, mentioned before, into a vertical one. The plumb-wire hangs from an angle at the upper end, againſt which it is drawn into cloſe contact by the weight below, and is here conſidered as depending from a fixed point. At the lower end the main tube is croſſed at right angles by two ſmaller tubes; one of them parallel to the teleſcope, the other parallel to the axis. At one end of each is placed a luminous point, formed by a fine round hole, in a braſs pin, which is ſet in a diaphragm of mother-of-pearl; a lens in the ſame tube forms an image of the luminous point, upon the plumb-line, in the axis of the main tube. Theſe are viewed by eye-glaſſes in the oppoſite ends of the croſſing tubes, by which the plumb-line is ſeen directly paſſing through the image of the luminous point, which appears like the diſc of a ſmall planet. The tube which is parallel to the teleſcope regards the axis, and that which is parallel to the axis regards the reading microſcopes; by adjuſtments in the former, and reverſing the poſition of the inſtrument, the axis may be ſet truly level, and by ſimilar adjuſtments in the latter, and the ſame means, the reading microſcopes are brought to ſhew the true zenith diſtance. It ſhould have been mentioned, perhaps ſooner, that a ſmall pincher takes hold of the lower end of the plumb-line, the weight of which is ſufficient to paſs the wire through the main tube, having a hook at the lower end by which it is connected with the plummet. A cap ſcrews into the lower end of the main tube, furniſhed with a bolt for ſecuring the pincher, thereby preventing the plumb-line, when out of uſe, from being entangled or broken. By theſe means, the plumb-line is always in its place, ready for uſe, and the parts of the inſtrument are verified thereby in a few minutes.

The mechaniſm of the eye-piece of the teleſcope is intereſting, and in many reſpects new. The eye-glaſs, by touching a lever which is connected with a pinion, is carried along parallel to the axis, and readily ſet oppoſite any of the wires in obſerving a tranſit. This motion may in a moment be changed into a vertical one, while the upper and lower limbs of the ſun or moon are brought in contact with the declination wires. At about half the mean diameter of the ſun from the central horizontal wire, is a fixed wire on one ſide, and on the other ſide a moveable one all parallel; the latter is acted on by a micrometer ſcrew, which marks the quantity of motion by a nice graduation, croſſing the central wire a little way, but in its proper direction meaſures about 40′. By theſe contrivances, while the right aſcenſion of the ſun or moon is obſerved, without the loſs of a ſingle contact, one limb may be brought to the fixed wire, and the moveable wire ſet to the other limb, and the whole may be read off after the obſervation is finiſhed. We have ſpoken of the wires here, and elſewhere in Troughton's inſtruments, as though they were always metallic, but in many of his inſtruments he has introduced the fine threads ſpun by a ſpider, which are not only ſmaller than any other, but, what will appear remarkable, will bear the focal rays of the ſun without injury. A ſpirit level half the length of the axis, hangs upon two pivots, which project from two cocks ſcrewed faſt to the axis, on theſe it turns, and by its gravity keeps the right ſide up, and thus ſhews the level of the axis in every poſition of the teleſcope. This level does not appear in the plate, being completely hid behind the axis. Another level, ſeen in the figure, hangs upon two pivots which are attached to the eye-end of the teleſcope: this, on being brought to an horizontal poſition, will verify the adjuſtments of the microſcopes and other parts more quickly than the plumb-lines; it is not however ſo accurate. The axis is perforated, and by an illuminator placed at a proper angle in the centre, the light of a lamp placed oppoſite one end of the axis is reflected to the eye, and ſhews the wires by night. The quantity of light is regulated by letting it paſs through glaſſes differently coloured. Other parts, (ſuch as the circular plates at the object-ends of the microſcopes, furniſhed with univerſal motion, for illuminating the diviſions of the limbs), moſtly common to all inſtruments, are ſeen in the figure, but do not require particular notice.

In an obſervatory where there is but one inſtrument, the one under conſideration ſeems to be the beſt, though aſtronomers are not quite agreed upon this ſubject, ſome thinking, that the right aſcenſion, and declination inſtruments ſhould ever be ſeparate; they all, however, confeſs now, that, in an obſervatory, the azimuth circle is of little value.

It is reported that a large mural tranſit circle is in contemplation for Greenwich, (where, when there are two obſervers, it cannot be wanted) which promiſes to be greatly ſuperior, for the purpoſe of obſerving the declinations of the heavenly bodies, to any that has yet been ſeen; but this has not yet been even ordered, and therefore cannot now be given; ſhould it however be executed, we may hereafter

hereafter present our readers with its figure and description under the article *Observatory*, or some other appropriate title.

In our description of this our last instrument, coming under the denomination of a CIRCLE, we have judged it expedient to omit the letters of reference, except in three instances, partly because the figure being already sufficiently crowded would thereby be rendered less distinct, and partly because the reader, who has perused the accounts of the other circles, cannot but understand the parts that have been verbally described, when he has the figure before him, and therefore will not be sorry to dispense with a long alphabetical enumeration of the different parts. It may be proper to subjoin, before we take our leave of the subject, that, as there is no azimuth circle in the instrument at present before us, the *reversed* adjustment and *reversed* observation are effected, by carefully lifting the whole circle out of the angles of bearing, and returning it when the ends of the axis are reversed; which is a more certain way of making the second position of the telescope at 180° from the former, than can be expected by any method that requires measurement, even when a distant object is viewed as a mark; for a deviation of the central wire from the true line of collimation, may escape notice, and deceive the observer.

In the Philosophical Transactions of London, for the year 1806, is a description of an astronomical circle of John Pond Esq. of Westbury, as made for him by Troughton; with which instrument, aided by Dr. Hamilton's observations at Armagh, and Piazzi's at Palermo, he has corrected the declinations of many stars as given in Dr. Maskelyne's Catalogue published in 1802. The account is copied by Mr. Nicholson in his Journal for March 1807, but without the table of observations, as annexed in the original.

Another of Troughton's astronomical circles may also be seen described in Count Bruhl's pamphlet, entitled "On the Investigation of astronomical Circles," which is an interesting publication.

If it should be remarked by any of our readers, that we appear to have been partial to Troughton, in our selection of circular instruments, our answer is, that we have found in him not only a very intelligent, but a communicative man, who, moreover, was ever ready to procure access to our draftsman to the instruments we wanted, though not in his own possession: besides, when we consider that his instruments are not only made in the most perfect manner, but have never before been described, we presume the public will thank us and him, for the opportunity we here give the world of being acquainted with the characteristic marks of their construction. With respect to ourselves, we cannot in justice do less than publicly thank Mr. Troughton for the aid he has afforded us in this article, which, however, we should have withheld from motives of delicacy, did we not conceive that his well earned fame soars far above the reach of any support of ours.

CIRCLE, CIRCULUS, in *Geometry*, a plane figure, comprehended under one single line, which returns into itself, having a point in the middle, from which all the lines, drawn to its circumference, and called radii, are equal.

Properly speaking, it is the space included within the circumference, or periphery, that is the circle: though in the popular use of the word, circle is frequently used for the periphery alone. See CIRCUMFERENCE and DEGREE.

We shall here introduce some of the chief properties of the circle, referring for others to the articles ANGLE, CHORD, CIRCUMFERENCE, DIAMETER, POLYGON, SINE, TANGENT, TRAPEZIUM, &c.

1. Any two chords of a circle, equally distant from its centre, are equal to each other. Let O (*Plate* III. *Geometry*, *fig.* 49.) be the centre, A B and D E two chords; and having let fall the perpendiculars, O C, O F, draw the radii O A and O D. The triangles, O F D and O C A, have evidently the sides and angles equal; and therefore A C or $\frac{1}{2}$ A B (see CHORD) = F D or $\frac{1}{2}$ D E: consequently A B = D E.

2. The angle B D C (*fig.* 50.) at the centre of a circle is double of the angle B A C at the circumference, when both stand upon the same arc, B C. Drawing the diameter, A D E, it is plain (No. 1.) that, as the angles at the base of an isosceles triangle are equal, and the external angle of a triangle is equal to both the internal and opposite angles, B D C is = A + C = 2A. In No. 2. B D E = 2B A E, and E D C = 2E A C, ∵ by addition B D C = 2B A C. In No. 3 C D E = 2C A E, and B D E = 2B A E, ∵ by subtraction B D C = 2B A C.

Hence, 3. All angles in the same segment of a circle, or standing upon the same arc, whether that segment be greater or less than a semicircle, are equal to each other.

4. Angles D, G, (*fig.* 51.) in the circumferences, standing upon equal subtenses, A B, E F, of circles, having equal diameters, are equal to each other; and *vice versâ*. From the centres, P and Q, draw the radii P A, P B, and Q E, Q F. Since A B = E F, and the radii are equal, the triangles, A P B, E Q F, are mutually equilateral, and consequently equiangular; ∵ P = Q, and D = $\frac{1}{2}$ P = $\frac{1}{2}$ Q = G. Moreover, D being supposed = G, P will be equal to Q, and the two triangles, A P B and E Q F, having two sides and the included angles respectively equal, have A B = E F.

5. The angle, A C B, (*fig.* 52.) in a semicircle is a right angle. For, drawing the diameter, A C D = $\frac{1}{2}$ A D E (by art. 2.) and B C D = $\frac{1}{2}$ B D E; ∵ A C B = $\frac{1}{2}$ A D E + $\frac{1}{2}$ B D E = half two right angles = one right angle.

6. If two lines, D E B, C E A, intersect each other within or without a circle, the angle, D E C, (*fig.* 53.) is equal, in the former case, to the sum, and in the latter, to the difference of two angles in the circumference, standing on the two arcs intercepted by those lines. Draw the chord, C B; and, *first*, D E C, the external angle, = D B C + A C B, the sum of the two internal angles; and, *secondly*, D E C, one of the internal angles, = D B C − A C B, the difference of the external angle and the other internal angle. Hence, an angle formed below or above the circumference of a circle, is greater or less than an angle in the circumference, standing on the same arc.

7. If an oblique-angled triangle, A C B, (*fig.* 54.) be inscribed in a circle, its vertical angle, A B C, will be greater or less than a right angle, by the angle C A D, comprehended under the base A C, and the diameter, A D, drawn from the extremity of the base. For, drawing B D, A B D will be a right angle, and C A D = C B D (by art. 3.); ∵ 1st, A B C = a right angle + C A D, and, 2dly, A B C = a right angle − C A D.

8. Inscribe a quadrilateral, A B C D, (*fig.* 55.) in a circle, and produce the side, B C, out of it, and the external angle, E C D, will be equal to the opposite internal angle, B A D. Draw the diameter, and join A F and C F; then the angle, B A F, in a semicircle, being a right angle (= B C F) = E C F, also a right angle, and D A F = D C F (by art. 3.); we shall have the remainders B A D and E C D equal. Hence it follows, that the opposite angles, B A D, B C D, of a quadrilateral inscribed in a circle, are, together, equal to two right angles; for B A D being = E C D, we shall have B A D + B C D = E C D + B C D = two right angles. Hence also, if the opposite angles of a quadrilateral be equal to two right angles, a circle may be described about that quadrilateral. Hence, also, it appears, that

that no oblique-angled parallelogram can have a circle deſcribed about it; becauſe its oppoſite angles being equal, their ſums muſt together, be either greater or leſs than two right angles.

9. The right lines, BE, CE, and BF, CF, (*fig.* 56.) drawn by pairs from two points, B and C, at equal diſtances in the ſame diameter from the centre of a circle, to meet in the circumference; the ſums of the ſquares of any two correſponding ones will be reſpectively equal. For, drawing OE and OF, $BE^2 + CE^2 =$ (ſee TRIANGLE) $2BO^2 + 2OE^2 \; (2OF^2) = BF^2 + CF^2$. Hence, $BE^2 + CE^2 = AC^2 + CD^2$. For, $BE^2 + CE^2 = 2BO^2 + 2OE^2 = 2AO^2 + 2OC^2$. But $AC^2 + CD^2 = \overline{AO + OC}^2 + \overline{AO - OC}^2 = AO^2 + OC^2 + 2AO \times OC + AO^2 + OC^2 - 2AO \times OC = 2AO^2 + 2OC^2 = BE^2 + CE^2$.

10. If two lines, AB, CD, (*fig.* 57.) terminated at each extremity by the circumference, interſect each other within a circle, the rectangle $AP \times BP$, under the parts of the one, will be equal to the rectangle, $CD \times DP$, under the parts of the other. If one line paſſes through the centre, (No. 1.) and OQ be drawn perpendicular to the other line, then, joining O and C, $QC = QD$ (ſee CHORD), and $DP = CQ - PQ$; but the rectangle under the ſum and difference of the two ſides, OC, OP, of any triangle, COP (ſee TRIANGLE), is equal to the rectangle under the whole baſe, CP, and the difference of its two ſegments; conſequently, ſince $OC + OP = OA + OP = AP$, and $OC - OP = OB - OP = BP$, the rectangle $AP \times BP = CP \times DP$. If neither of the two lines paſs through the centre (No. 2.), draw the diameter, EPF, and, by the former caſe, $AP \times BP = FP \times EP = CP \times DP$.

11. If two lines, AP, CP, (*fig.* 58.) be drawn from two points, A, C, in the circumference of a circle, and produced to meet without the circle, the rectangle, $AP \times BP$, contained under the whole and external part of the one will be equal to the rectangle, $CP \times DP$, contained under the whole and external part of the other. Draw PF through the centre, make OQ perpendicular to AP, and join A and O: then the rectangle $PF \; (= PO + OA) \times PE \; (= PO - OA)$ is $= AP \; (= PQ + QA) \times PB \; (= PQ - QA)$. In the ſame manner, $PF \times PE = CP \times DP$: conſequently $AP \times BP = CP \times DP$. Hence, if PS be a tangent at S, and the radius, OS, be drawn; it follows, ſince $PF = PO + OS$, and $PE = PO - OS$, that $PS^2 \; (= PF \times PE) = PC \times PD$. Hence, alſo, if another tangent, PT, be drawn, and the radius, OT, PT will be $= PS$, *i. e.* two tangents drawn from the ſame point to the ſame circle are equal, becauſe the two triangles, POT, POS, are right-angled, and have two ſides of the one equal to two ſides of the other.

12. If a line, CA, (*fig.* 59.) be drawn from C, the centre of a circle, to a point, A, in any chord, BD, the ſquare of that line, together with the rectangle contained under the two parts of the chord, will be equal to the ſquare of the radius of the circle. Let EAF be another chord perpendicular to CA, and C, E be joined. Since $EA = AF$ (ſee CHORD), $AE^2 = AE \times AF = AB \times AD$ (art. 10.); and, adding to each quantity AC^2, we ſhall have $CE^2 \; (= CA^2 + AE^2) = AB \times AD + AC^2$. Hence it follows, that the ſquare of a line, CA, drawn from any point in the baſe of an iſoſceles triangle, BCD, to the oppoſite angle, together with the rectangle of the parts of the baſe, is equal to the ſquare of one of the equal ſides of the triangle.

13. The rectangles contained under the correſponding ſides of equiangular triangles, ABC, DEF, (*fig.* 60.) taken alternately, are equal; *i. e.* $AB \times DF = AC \times DE$. Produce BA, take $AG = DF$, and let the circumference of a circle paſs through the three points, B, C, G, and meet CA produced in H, and G, H be joined. The triangles, GAH and DEF, having the angle $H = B$ (ſtanding upon the ſame arc) $= E$, and $HAG = BAC$ (as vertical) $= D$, and the ſide $AG = DF$, we have alſo $AH = DE$; and therefore $AC \times DE = AC \times AH = AB \times AG = AB \times DF$.

14. The rectangle under the two ſides AC, BC, of any triangle ABC (*fig.* 61.) is equal to the rectangle under CD, perpendicular to its baſe, and the diameter, CE, of the circumſcribing circle. For, B and E being joined, the angles, A and E, will be equal, and ADC, EBC, are both right angles; conſequently the triangles, ACD, ECB, are equiangular; and, as AC and EC, CD and CB are correſponding ſides, the rectangle $AC \times CB = EC \times CD$, by the laſt article.

15. The rectangle of the two diagonals, AC, BD, of any quadrilateral, ABCD (*fig.* 62.), inſcribed in a circle, is equal to the ſum of the two rectangles, $AB \times DC$, $AD \times BC$, contained under the oppoſite ſides. Draw BF, and make the angle $CBF = ABD$. The triangles, CBF, DBA, are evidently equiangular, and the rectangles, $BC \times AD$, $BD \times CF$, under the correſponding ſides, taken alternately, are equal. The triangles ABF and BDC are alſo equiangular, and the rectangles $AB \times DC$, and $BD \times AF$ are equal, as before: to theſe latter rectangles let the former be reſpectively added, and we ſhall have $AB \times DC + BC \times AD = BD \times AF + BD \times CF = BD \times AC$. We are indebted to Ptolemy for the knowledge of this property, applied to the conſtruction of his table of arcs and chords.

16. A perpendicular, CD (*fig.* 63.) let fall from the right angle upon the hypothenuſe, AB, of a right-angled triangle ABC, will be a mean proportional between the two ſegments, AD, BD, of the hypothenuſe; and each of the ſides, containing the right angle, will be a mean proportional between its adjacent ſegment, and the whole hypothenuſe. For the triangles BDC, BCA are equiangular, as are alſo ADC, ABC, and ADC, BDC; conſequently, as the correſponding ſides of equiangular triangles are proportional, $BD : CD :: CD : AD$; $AB : BC :: BC : BD$; and $AB : AC :: AC : AD$. Hence it follows, and alſo by art. 5, that, if from any point C, in the circumference of a ſemicircle, a perpendicular, CD, be let fall upon the diameter AB, and two chords, CA, CB, be drawn from the ſame point, C, to the extremities of that diameter, the ſquare of the ſaid perpendicular will be equal to a rectangle, under the two ſegments of the diameter; and the ſquare of each chord will be equal to a rectangle under the whole diameter, and its adjacent ſegment; *i. e.* $CD^2 = BD \times AD$, $BC^2 = AB \times BD$, and $AC^2 = AB \times AD$. The firſt of theſe properties gives us what is uſually called "the equation of the circle:" for, if d denote the diameter AB, x the abſciſs AD, and y the ordinate CD, we ſhall have $y^2 = x \times \overline{d - x} = dx - x^2$. Hence it alſo follows, that if another chord, AE, be drawn, and a perpendicular, EF, be let fall upon the diameter, the ſquares of the chords will be as the ſegments of the diameter; *i. e.* $AD : AF :: AC^2 : AE^2$, for $AC^2 = AB \times AD$, and $AE^2 = AB \times AF$, $\because AC^2 : AE^2 :: AB \times AD : AB \times AF :: AD : AF$.

17. If a line PFC, (*fig.* 64) be drawn perpendicular to

to the diameter A D of a circle, and any line be drawn from A to interfect the circle and perpendicular; the rectangle of the diftances of the points of interfection from A will be equal to the rectangle of the diameter, and the diftance of the perpendicular from A; *i. e.* $AB \times AC = AP \times AD$. For, if B D be drawn, the triangles A B D, A P C, having the angle at A common, and the angles at P and B right, are equiangular and fimilar; confequently $AD : AB :: AC : AP$, and $AD \times AP = AB \times AC$. Hence, if P F interfects the circle in K, $AB \times AC = AK^2$; and if more lines be drawn, all the rectangles $EA \times AF$, $BA \times AC$ are equal, becaufe they are all refpectively equal to the rectangle $AD \times AP$.

18. If, in a circle E D F (*fig.* 65), whofe centre is C, and radius C E, the points B, A, be fo placed in the diameter produced, that C B, C E, C A, be in continual proportion, two lines, B D, A D, drawn from thefe points to any point in the circumference of the circle, will always be in the given ratio of B E to A E. For, drawing D P perpendicular to the diameter E F, $DP^2 = EP \times PF$ (art. 16) $= 2CE \times EP - EP^2$; whence $AD^2 = \overline{AE + EP}|^2 + PD^2 = AE^2 + EP^2 + 2AE \times EP + 2CE \times EP - EP^2 = AE^2 + 2CE \times EP + 2AE \times EP$. Alfo $BD^2 = \overline{BE - EP}|^2 + PD^2 = BE^2 - 2BE \times EP + EP^2 + 2CE \times EP - EP^2 = BE^2 + 2CE \times EP - 2BE \times EP$. But C A, CE, and C B, are in continued proportion, therefore $AE : CE :: EB : CB$, or $AE : EB :: CE : CB$. Alfo, $AE^2 : EB^2 :: CE^2 : CB^2 :: CA : CB :: CE + AE : CE - EB :: 2CE \times EP + 2AE \times EP : 2CE \times EP - 2EB \times EP$. And $AE^2 : EB^2 :: AE^2 + 2CE \times EP + 2AE \times EP : EB^2 + 2CE \times EP - 2EB \times EP :: AD^2 : BD^2$. Confequently, $AE : EB :: AD : BD$.

19. If any chord, P Q, (*fig.* 66), be drawn parallel to the diameter A B of a circle, and from a given point C, in that diameter, the lines C P, C Q, be drawn to the extremities of the chord; the fum of the fquares of thefe lines is equal to the fum of the fquares of the fegments of the diameter; *i. e.* $CP^2 + CQ^2 = AC^2 + CB^2$. For, drawing P S, Q R perpendicular to the diameter AB, we fhall have PS^2, or $QR^2 = PC^2 - SC^2 = QC^2 - RC^2$, *i. e.* $PC^2 - \overline{SO + OC}|^2 = QC^2 - \overline{SO - OC}|^2$; or $PC^2 - SO^2 - 2SO \times OC - OC^2 = QC^2 - SO^2 + 2SO \times OC - OC^2$, becaufe $OR = OS$. Confequently $PC^2 = QC^2 + 4\overline{SO \times OC}$; but $AC^2 + CB^2 = \overline{AO + OC}|^2 + \overline{AO - OC}|^2 = 2AO^2 + 2OC^2$. But $PC^2 = AO^2 + OC^2 + 2SO \times OC = QC^2 + 4\overline{SO \times OC}$. Confequently, $QC^2 = AO^2 + OC^2 - 2\overline{SO \times OC}$, and $PC^2 = AO^2 + OC^2 + 2\overline{SO \times OC}$; $\because PC^2 + QC^2 = 2AO^2 + 2OC^2 = AC^2 + CB^2$.

N. B. It will be the fame, if the point C be taken without the circle.

20. The circle is the moft capacious of all plain figures, or it contains the greateft area within the fame perimeter, or it has the leaft perimeter about the fame area; being the limit and laft of all regular polygons, having the number of its fides infinite. See POLYGON.

21. The area of a circle is always lefs than the area of any regular polygon circumfcribed about it, and its circumference always lefs than the perimeter of the polygon. But on the other hand, its area is always greater than that of its infcribed polygon, and its circumference greater than the perimeter of the faid infcribed polygon. Neverthelefs, the area and perimeter of the circle approach nearer and nearer to thofe of the two polygons, as the number of their fides increafes; the circle being always limited between the two polygons.

22. The area of a circle is equal to that of a triangle whofe bafe is equal to the circumference, and altitude equal to the radius. *N. B.* This was firft demonftrated by Archimedes in his treatife entitled Κυκλου Μετρησις, or Circuli Dimenfio.—Prop. I. Or, the area of a circle, *e. g.* A C E (*fig.* 67.) is equal to a rectangle, O R S T, under its radius O R, and a right line, O T, equal to half the circumference. It is evident, in the firft place, that the propofed rectangle, O R S T, is greater than any polygon, A B C D E F, that can be defcribed in the circle; for, drawing O A, O B, &c. and alfo O v perpendicular to A B, it is plain, that the triangle A O B ($Ov \times \frac{1}{2} AB$) will be lefs than $OA \times \frac{1}{2} AB$, or $OR \times \frac{1}{2} AB$. In the fame manner, B O C is lefs than $OR \times \frac{1}{2} BC$, &c. Confequently, the whole polygon A B C D E F is lefs than $OR \times \frac{1}{2} AB + OR \times \frac{1}{2} BC$, &c.; that is, lefs than a rectangle (Om) under O R and Op = half the perimeter ($AB + BC + CD$, &c.) But this rectangle Om is itfelf lefs than O S, becaufe Op (half the perimeter of the polygon) is lefs than O T (half the circumference of the circle). Confequently, the polygon A B C D E F is lefs than the rectangle O S. But it will apppear, in the fecond place, that the fame rectangle O R S T is lefs than any polygon H I K L M N that can be defcribed about the circle: for, if O H, O I, &c. be joined, and the radius O P be drawn to the point of contact of H I, then the triangle H O I will be $= OP \times \frac{1}{2} HI = OR \times \frac{1}{2} HI$. In the fame manner, $IOK = OR \times \frac{1}{2} IK$, &c.; and, therefore, the whole polygon H I K L M N $= OR \times \frac{1}{2} HI + OR \times \frac{1}{2} IK$, &c. = a rectangle ($On$) under O R and Oq = half the perimeter ($HI + IK + KL$, &c.), which rectangle is, manifeftly, greater than O S, fince Oq (= half the perimeter of the polygon) is greater than O T. Hence, therefore, as the rectangle O S is greater than any polygon that can be infcribed in the circle, and lefs than any polygon that can be defcribed about it; it muft be equal to the circle itfelf.

Hence, in order to find the area of a circle, half the circumference is to be multiplied into half the diameter, or the whole circumference into the whole diameter and a fourth part of the product be taken.

This rule may be otherwife demonftrated, by the aid of fluxions. Put r = the radius AC, (*fig.* 68.) c = the whole circumference A E B A, or any part of it, and x = the radius C D of a circle continually expanded. Then $\frac{c}{r} x\dot{x}$ will exprefs the fluxion of the whole circle or fector whofe circumference is c; and, confequently, $\frac{cxx}{2r}$ = the area C D F; and $\frac{1}{2} cr$ = the area C A E of the whole circle or fector accordingly. Otherwife, multiply the fquare of the diameter by .7854, and the product will be the area. For the proof of this rule it fhould be obferved, that all circles, being fimilar figures, are as the fquares of their diameters, (fee next article); confequently, by the preceding article, the area of a circle whofe diameter is 1, is $\frac{1 \times 3.14159, \&c.}{2 \times 2 = 4} = .78539$, &c.; whence $1^2 : d^2$ (the fquare of any diameter) :: .78539, &c. : .78539 d^2, the area of the circle, whofe diameter is d. Hence, and from the next article, fuppofing D the diameter, C the circumference, and A the area of any circle, and p = 3.14159, &c. we may deduce the following equations: *viz.*

2. D

$$1.\ D = \frac{C}{p} = \frac{4A}{C} = 2\sqrt{\frac{A}{p}}.$$

$$2.\ C = pD = \frac{4A}{D} = 2\sqrt{pA}.$$

$$3.\ A = \frac{pD^2}{4} = \frac{C^2}{4p} = \frac{DC}{4}.$$

$$4.\ p = \frac{C}{D} = \frac{4A}{DD} = \frac{CC}{4A}$$

Hutton's Menſ. p. 128, &c.

Other rules may eaſily be formed by aſſuming different numbers for expreſſing the proportion of the diameter to the circumference. See each of theſe articles.

23. All circles, like other ſimilar plane figures, are to one another as the ſquares of their diameters or radii. Let A C E and *ace* (*fig.* 69) be two circles, and they will be as the ſquares of their radii, or AO^2 to ao^2. Let Q be to the circle *ace* :: $AO^2 : ao^2$; and Q = circle A C E. For, *firſt*, it is evident, that Q is greater than any polygon A B C D E F that can be inſcribed in the circle A C E; becauſe, if another polygon, *abcdef*, ſimilar to it, be inſcribed in the circle *ace*; then we ſhall have the polygon A B C D E F : polyg. *abcdef* (:: $AO^2 : ao^2$) :: Q : circle *ace*; but the firſt conſequent being leſs than the ſecond, the firſt antecedent A B C D E F muſt be leſs than the ſecond Q. In the ſame manner it will appear, that Q is leſs than any polygon H I K L M N that can poſſibly be deſcribed about the circle A C E; for deſcribing another ſimilar polygon *hiklmn* about the circle *ace*, we ſhall have H I K L M N : *hiklmn* (:: $AO^2 : ao^2$) :: Q : circle *ace*; but the firſt conſequent is greater than the ſecond, and, therefore, the firſt antecedent muſt be greater than the ſecond Q. Conſequently, as Q is greater than any polygon that can be inſcribed in the circle A C E and leſs than any polygon that can be deſcribed about it, it muſt be equal to the circle: whence A C E : *ace* :: $AO^2 : ao^2$. According to Archimedes, the area of the circle is to the ſquare of the diameter, as 11 to 14, or, more nearly, as .7854 to 1; or ſtill more nearly, as

.7853981633,9744830961,5660845819,8757210492, 9234984377,6455243736,1480769541,0157155224, 9657008706,3355292669,9553702162,831807666, 7734611 + to 1; as it has been found by modern mathematicians. Dr. Wallis's "Arithmetic of Infinites" contains the firſt infinite ſeries for expreſſing the ratio of a circle to the ſquare of its diameter: *viz.*

1ſt. The circle is to the ſquare of its diameter

$$\left.\begin{array}{l} \text{As 1 to } \dfrac{3 \times 3 \times 5 \times 5 \times 7 \times 7,\ \&c.}{2 \times 4 \times 4 \times 6 \times 6 \times 8,\ \&c.} \\ \text{Or 1 to } \dfrac{9}{8} \times \dfrac{25}{24} \times \dfrac{49}{48},\ \&c. \end{array}\right\}\ \text{found out by Wallis himſelf.}$$

$$\text{Or as 1 to } 1 + \cfrac{1}{2 + \cfrac{9}{2 + \cfrac{25}{2 + \cfrac{49}{2 \times \&c.}}}}, \text{ by lord Brounker;}$$

$$\text{Or as } 1 - \frac{1}{2 \times 3} - \frac{1}{2 \times 4 \times 5} - \frac{1 \times 3}{2 \times 4 \times 6 \times 7} - \frac{1 \times 3 \times 5}{2 \times 4 \times 6 \times 8 \times 9}, \&c. \text{ to 1, by ſir Iſaac Newton;}$$

$$\text{Or as } 1 - \frac{1}{3} + \frac{1}{5} - \frac{1}{7} + \frac{1}{9} - \frac{1}{11}, \&c. \text{ to 1, by Gregory and Leibnitz:}$$

and many other forms of ſeries have been invented by different authors, for expreſſing the ſame ratio between the circle and the circumſcribed ſquare. See QUADRATURE.

24. The circumferences of all circles, *e. g.* A B C D, *abcd* (*fig.* 70.) are in the ſame proportion as their diameters, or their radii, O B, *ob*. Let O E, *oe*, be ſquares on the radii O B, *ob*; and let O G, *og*, be two rectangles contained under the ſame radii and right lines O H, *oh*, reſpectively equal to the ſemi-circumferences A B C, *abc*. Then, theſe rectangles being equal to the circles themſelves, we ſhall have O E : O G :: *oe* : *og*. The baſes alſo, O C, O H, *oc*, *oh*, are in the ſame ratio; whence (by equality and alternation) O C (O B) : *oc* (*ob*) :: O H : *oh* :: 2 O H (circumference A B C D) : 2 *oh* (circumference *abcd*.) As the areas of circles are proportional to the rectangles of their radii and circumferences, the quadrature of the circle would be effected by the rectification of its circumference; or in other words, if the length of the circumference could be accurately aſcertained, the true area might alſo be found. Many attempts have been made, in the way of approximation, to accompliſh this object, and different reſults, aproaching nearer and nearer to the truth, have been obtained from different proportions of the diameter to the circumference: but, after all, the determination of the true area of the circle has been generally thought impracticable. For an account of what has been done in this way by ancient and modern mathematicians, ſee the articles DIAMETER, CIRCUMFERENCE, QUADRATURE, and RECTIFICATION.

Beſides the foregoing well-known properties of the circle, it may not be improper to give the formations of the following very beautiful, general, and intereſting theorems reſpecting it, which were publiſhed at Edinburgh in 1746, by the late Dr. Matthew Stewart, the ſucceſſor of Mr. Maclaurin, without demonſtrations, and remained ſo for a period of 59 years, till 1805, when they were not only demonſtrated by James Glenie, eſq. A.M. F.R.S. Lond. and Edin. in a paper printed in the "Philoſophical Tranſactions of the Royal Society of Edinburgh," for that year, but alſo derived as mere corollaries from a general geometrical inveſtigation delivered by him in the ſaid paper. They are the following:

Let there be any regular figure of a greater number of ſides than three circumſcribed about a circle, and from any point in the circumference of the circle let there be drawn perpendiculars to the ſides of the figure; twice the ſum of the cubes of the perpendiculars will be equal to five times the multiple of the cube of the ſemi-diameter of the circle by the number of the ſides of the figure. Thus, if n denote the number of the ſides of the figure, and r the radius or ſemi-diameter of the circle, twice the ſum of the cubes of theſe perpendiculars will be equal to $5nr^3$.

Let there be any regular figure circumſcribed about a circle of a greater number of ſides than three, and from any point within the figure let there be drawn perpendiculars to the ſides of the figure, and likewiſe let there be drawn a right line to the centre of the circle; twice the ſum of the cubes of the perpendiculars drawn to the ſides of the figure, will be equal to twice the multiple of the cube of the ſemi-diameter of the circle by the number of the ſides of the figure, together with thrice the multiple by the ſame number of the ſolid, whoſe baſe is the ſquare of the line drawn to the centre, and altitude the ſemi-diameter of the circle.

Thus, if n denote the number of the ſides of the figure, and l the line drawn from the point within the figure to the

centre

centre of the circle, twice the ſum of the cubes of theſe perpendiculars will be equal to $2nr^3 + 3l^2r$.

Let there be any regular figure inſcribed in a circle, and from all the angles of the figure let there be drawn right lines to any point in the circumference of the circle; the ſum of the fourth powers of the chords will be equal to ſix times the multiple of the fourth power of radius, or the ſemidiameter of the circle, by the number of the ſides of the figure.

Let there be any regular figure inſcribed in a circle, and from all the angles of the figure and the centre of the circle let there be drawn right lines to any point; the ſum of the fourth powers of the lines drawn from the angles of the figures, will be equal to the multiple by the number of the ſides of the figure of the fourth power of the ſemi-diameter of the circle, together with four times the multiple by the ſame number of the fourth power of the line, whoſe ſquare is equal to the rectangle contained by the ſemi-diameter and the line drawn from the centre, together with the multiple by the ſame number of the fourth power of the line drawn from the centre.

Let there be any regular figure of a greater number of ſides than four circumſcribed about a circle, and from any point in the circumference of the circle, let there be drawn perpendiculars to the ſides of the figure; 8 times the ſum of the fourth powers of the perpendiculars will be equal to 35 times the multiple by the number of the ſides of the figure, of the fourth power of the ſemidiameter of the circle.

Let there be any regular figure of a greater number of ſides than four circumſcribed about a circle, and from *any point* let there be drawn perpendiculars to the ſides of the figure, and likewiſe a right line to the centre of the circle; 8 times the ſum of the fourth powers of the perpendiculars will be equal to eight times the multiple by the number of the ſides of the figure of the fourth power of the ſemidiameter of the circle, together with 24 times the multiple by the ſame number of the fourth power of the line, whoſe ſquare is equal to the rectangle contained by the ſemidiameter, and the line drawn to the centre, together with 3 times the multiple of the fourth power of the line drawn to the centre of the circle by the number of the ſides of the figure.

And in general, let there be any regular figure circumſcribed about a circle; and let the number of the ſides of the figure be n, and let m be any number leſs than n; let r be the ſemidiameter of the circle; and from any point in the circumference of the circle let there be drawn perpendiculars to the ſides of the figure, the ſum of the m powers of the perpendiculars will be equal to $n \times \frac{1 \cdot 3 \cdot 5 \cdot 7 \cdot \cdot \cdot 2m - 1}{1 \cdot 2 \cdot 3 \cdot 4 \cdot \quad \cdot \cdot \cdot \cdot m}$ $\times rm$, in which expreſſion the numbers in the numerator are to be continued, till the laſt number be equal to $2m - 1$ and are to be continually multiplied into one another, and thoſe in the denominator are to be continued till the laſt number be m, and are to be continually multiplied into one another.

Let there be any regular figure circumſcribed about a circle, and let n be the number of the ſides of the figure; let m be any number leſs than n, and let r be the ſemidiameter of the circle; and from any point (within the figure, if m be an odd number, but if even from any point either within or without) let there be drawn perpendiculars to the ſides of the figure; and likewiſe let there be drawn a right line to the centre of the circle, and let v be the line drawn to the centre; let a be the co-efficient of the third term of a binomial raiſed to the m power, b the co-efficient of the fifth term, c the co-efficient of the ſeventh term, and ſo on; the ſum of the m powers of the perpendiculars will be equal to $nr^m + nAv^2r^{m-2} \times nBv^4r^{m-4} \times nCv^6r^{m-6} \times$, &c. ſubſtituting A for $a \times \frac{1}{2}$, B for $b \times \frac{1.3}{2.4}$, C for $c \times \frac{1 \cdot 3 \cdot 5}{2 \cdot 4 \cdot 6}$ and ſo on.

Let there be any regular figure inſcribed in a circle, and let the number of the ſides of the figure be n, and let m be any number leſs than n; let r be the ſemi-diameter of the circle; and from all the angles of the figure let there be drawn right lines to any point in the circumference of the circle; the ſum of the $2m$ powers of the chords will be equal $n \times \frac{1 \cdot 3 \cdot 5 \cdot 7 \cdots\cdots 2m - 1}{1 \cdot 2 \cdot 3 \cdot 4 \cdots\cdots m} \times 2^m r^{2m}$, in which expreſſion the numbers in the numerator are to be continued till the laſt number be $2m - 1$, and are to be continually multiplied into one another; and thoſe in the denominator are to be continued till the laſt number be m, and are to be continually multiplied into one another.

Theſe and a number of other general theorems reſpecting the circle are not only demonſtrated by Mr. Glenie, in a conciſe and ſimple manner in the ſaid curious geometrical paper, but are derived as mere corollaries from a general inveſtigation, that extends not only to regular but alſo to irregular figures circumſcribed about, and inſcribed in, the circle; and from which may eaſily be deduced an endleſs number of theorems much more general than even thoſe of Dr. Stewart, that remained for 59 years undemonſtrated, and though publiſhed without demonſtrations were the principal cauſe of his being appointed ſucceſſor to the celebrated Mr. Maclaurin.

For the method of inſcribing within the circle, or deſcribing about it triangles, polygons, quadrilaterals, ſquares, trapeziums, &c., and the properties thence reſulting, ſee the ſeveral articles.

For the method of deſcribing a circle through three given points, ſee CHORD.

For the mode of obtaining a circle from the ſection of a cone; ſee CONIC SECTION.

CIRCLES, *parallel* or *concentric*, are ſuch as are equally diſtant from each other in every point of their peripheries; or are deſcribed from the ſame centre; as, on the contrary, thoſe ſtruck from different centres are ſaid to be *eccentric*.

CIRCLE, *arc of*. See ARC.

CIRCLE, *the quadrature of the*, or the manner of making a ſquare, whoſe ſurface is perfectly and geometrically equal to that of a circle, is a problem that has employed the geometricians of all ages. See the article QUADRATURE.

CIRCLE, *ſector of a*. See SECTOR.

CIRCLE, *ſegment of a*. See SEGMENT.

CIRCLES *of the higher orders*, are curves wherein $AP^m : PM^m :: PM : PB$, or, $AP^m : PM^m :: PM^n : PB^n$. *Plate* V. *Geometry*, *fig*. 71. When m and n are each equal to 1, then $AP : PM :: PM : PB$, which is a property of the common circle. *Cor*. I. Suppoſe $AP = x$, $PM = y$, $AB = a$: then will $PB = a - x$. And conſequently $x^m : y^m :: y : a - x$. Hence we have an equation that defines infinite circles, viz. $y^{m+1} = ax^m - x^{m+1}$; and another defining other infinite circles, viz. $y^{m+n} = \overline{a - x}|^n x^m$.

Cor. II. If $m = 1$, then will $y^2 = ax - x^2$; and therefore a circle of the firſt order is contained under this equation alone. If $m = 3$, the equation becomes $y^4 = x^3, \overline{a - x}$ or $ax^3 - x^4$, which denotes a curve of the form A B (*fig*. 72). But when m denotes an even number, the curve will have two infinite legs; thus if $m = 2$, $y^3 = ax^2 - x^3$, which equation defines a circle of the ſecond order; and alſo one of Newton's defective hyperbolas, being his 37th ſpecies of curves,

curves, whose asymptote is the right line E F (*fig.* 73), making an angle of 40° with the absciss A B.

CIRCLE *of curvature*, in *Geometry*, that circle the curvature of which is equal to that of any curve at a certain point. It is also called the circle of equi-curvature. See CURVATURE.

CIRCLES *of the sphere*, are such as cut the mundane sphere, and have the periphery either on its moveable surface, or in another immoveable, conterminous, and equi-distant surface. Hence arise two kinds of circles, *moveable* and *immoveable*. The first are those whose peripheries are in the moveable surface, and which therefore revolve with its diurnal motion, as the meridians, &c. The latter, having their periphery in the immoveable surface, do not revolve; as the ecliptic, equator, and its parallels, &c.

If a sphere be cut in any manner, the plane of the section will be a circle, whose centre is in the diameter of the sphere. Hence the diameter of a circle passing through the centre, being equal to that of the circle which generated the sphere; and that of a circle which does not pass through the centre, being only equal to some chord of the generating circle; the diameter being the greatest of all chords; there hence arises another division of the circles of the sphere, *viz.* into *great* and *lesser*.

CIRCLE, *great, of the sphere*, is that which divides it into two equal parts, or hemispheres; having its centre in the centre thereof. Hence all great circles are equal, and cut each other into equal portions, or semicircles.

The great circles are the horizon, meridian, equator, ecliptic; the colures, and the azimuths; which see in their places.

CIRCLE, *lesser, of a sphere*, is that which divides the sphere into two unequal parts, and has its centre in the axis of the sphere, but not in the centre thereof. These are usually denominated from the great circles to which they are parallel; as parallels of the equator, &c.

CIRCLES *of altitude*, otherwise called *almucantars*, are lesser circles parallel to the horizon, whence they are also called parallels of altitude, having their common pole in the zenith, and still diminishing as they approach the zenith. They have their names from their use, which is to shew the altitude of a star above the horizon.

Some have suspected a variation in the apparent solstitial altitudes of the sun. Something of this kind was perceived by M. Cassini in 1655, by means of the great gnomon in the church of St. Petronius at Bologna; which was further confirmed by other observations at the royal observatory at Paris. The variation observed by M. Cassini, during the course of twenty-two years, only amounted to a few seconds. And by comparing the observation made by Pytheas at Marseilles three hundred years before Christ, with another made by Cassini in 1672 at the same place, it appears, that in two thousand years time this difference of altitude has only amounted to a few minutes. V. Mem. Acad. Scienc. 1693, p. 180, seq. See ECLIPTIC. See also ALTITUDE.

CIRCLES *of declination*, are great circles intersecting each other in the poles of the world.

CIRCLE *of dissipation*, in *Optics*. See the article DISSIPATION.

CIRCLES, *diurnal*, are immoveable circles, supposed to be described by the several stars, and other points of the heavens, in their apparent diurnal rotation round the earth.

Thus if a right line be conceived to be continued from the centre of a star, perpendicular to the axis of the world, as far as the surface of the sphere of the world, it will describe a diurnal circle for it, in making one revolution about its axis. The diurnal circles are all unequal: the equator is the greatest.

CIRCLE *equant*, in the *Ptolemaic Astronomy*, is a circle described on the centre of the equant. Its chief use is, to find the variation of the first inequality.

CIRCLES *of excursion*, are lesser circles parallel to the ecliptic, and at such a distance from it, as that the excursions of the planets towards the poles of the ecliptic may be included within them; being usually fixed at about 10 degrees.

It may here be added, that all the circles of the sphere above described, are transferred from the heavens to the earth; and thence come to have a place in geography, as well as in astronomy; all the points of each circle being conceived to be let fall perpendicularly on the surface of the terrestrial globe, and so to trace out circles perfectly similar to them. Thus, the terrestrial equator is a line, conceived precisely under the equinoctial line, which is in the heavens; and so of the rest.

CIRCLES, *horary*, in *Dialling*, are the lines which shew the hours on dials; though these be not drawn circular, but nearly straight.

CIRCLE, *horary, on the artificial globe*, a brazen circle fixed to the north pole divided into 24 hours, and furnished with an index, shewing the difference of meridians, and serving for the solution of many problems. The usual position of this circle prevents the brass meridian from moving quite round in the horizon; so that globes of the common sort cannot be applied to the purpose above mentioned. Mr. Harris contrived to remedy this inconvenience, by placing two horary circles under the meridian, one at each pole; these are fixed tight between two brass collars placed about the axis, but so that they may be easily turned by the hand when the globe is at rest; and when the globe is turned, they are carried round with it, the meridian serving as an index to mark out the horary division. The globe, thus prepared, will serve for solving problems in all latitudes, as well as in places near the equator. Philosophical Transactions abridged, vol. viii. p. 352. See GLOBE.

CIRCLE *of illumination*, is that imaginary circle on the surface of the earth, which is formed by a plane passing through the centre of the earth, so that the line which joins the centres of the sun and earth may be perpendicular to it, and which separates the illuminated hemisphere of the earth from the dark. This Mr. Keil calls the illuminated disc of the earth; and all lines passing from the sun to the earth, which are physically parallel, are perpendicular to the plane of this circle.

CIRCLES *of latitude*, or *secondaries of the ecliptic*, are great circles perpendicular to the plane of the ecliptic, passing through the poles thereof, and through every star and planet. They are so called, because they serve to measure the latitude of the stars, which is nothing but an arc of one of these circles, intercepted between the star and the ecliptic.

CIRCLES *of longitude*, are lesser circles, parallel to the ecliptic; still diminishing, in proportion as they recede from it. On the arcs of these circles, the longitude of the stars is reckoned.

CIRCLE *of perpetual apparition*, one of the lesser circles, parallel to the equator; described by any point of the sphere touching the northern point of the horizon, and carried about with the diurnal motion. All the stars included within this circle never set, but are always visible above the horizon.

CIRCLE *of perpetual occultation*, is another lesser circle at a like distance from the equator, described by the southern point

point of the horizon, and containing all thofe ftars which never appear in our hemifphere.

The ftars fituate between thefe circles alternately rife and fet at certain times, during the diurnal rotation.

CIRCLES, *polar*, are immoveable circles, parallel to the equator, and at a diftance from the poles equal to the greateft declination of the ecliptic, which is now 23° 28′.

That next the northern pole is called the *artic;* and that next the fouthern one the *antarctic;* which fee refpectively.

CIRCLES *of pofition*, are circles paffing through the common interfections of the horizon and meridian, and through any degree of the ecliptic, or the centre of any ftar, or other point in the heavens; ufed for finding out the fituation or pofition of any ftar. They are ufually fix in number; and cut the equator into twelve equal parts, which the aftrologers call the *celeftial houfes*. Hence fome call them *circles of the celeftial houfes*.

CIRCLE, *arc* or *arch of a*. See ARCH.

CIRCLE, *axis of a*. See AXIS.

CIRCLE, *centre of a*. See CENTRE.

CIRCLE, *eccentric*. See ECCENTRIC.

CIRCLE, *equal*. See EQUAL.

CIRCLE, *fairy*. See FAIRY.

CIRCLE, *right*. See RIGHT.

CIRCLE, *fegment of a*. See SEGMENT.

CIRCLES, *fecondary*. See SECONDARY.

CIRCLES, *vertical*, or *azimuths*. See VERTICAL, and AZIMUTH.

CIRCLE, in *Logic*, that fault of an argument that fuppofes the principle it fhould prove, and afterwards proves the principle by the thing it feemed to have proved.

Or, a circle in logic, called alfo *fyllogiftic circle*, is when the fame terms are proved, *in orbem*; by the fame terms; and the parts of the fyllogifm, alternately, by each other, both directly and indirectly.

Thus the papifts argue, when they prove the Scriptures to be the word of God by the infallible teftimony of their church, and the authority of the church by the Scripture.

There are two kinds of circles; the one *material*, the other *formal*.

The *formal* is that which in two reciprocal fyllogifms begs the medium, which is the next caufe of the greater extreme. This kind is by no means to be admitted: otherwife the fame thing becomes both prior and pofterior; the caufe and effect of itfelf; which is abfurd.

The *material* circle, called alfo *regreffus*, confifts of two fyllogifms, the former whereof proves the caufe by the effect; and the latter the effect by the caufe: this may be admitted.

CIRCLE, CIRCULUS, is underftood among the fchoolmen, of a viciffitude of generations, arifing one out of another. Thus, good concoction caufes a good habit of body; a good habit of body produces ftrength and vigour; thefe occafion frequent exercifes; and thefe a good concoction. It is a celebrated dogma of the Scotifts, "There is no circle in caufes of the fame order, or kind."

CIRCLES *of the empire*, are provinces, and principalities of the empire, compofed of princes, prelates, counts, and imperial cities, poffeffing a provincial and partial jurifdiction, and affembled for the regulation of their common affairs. See DIET.

The divifion of the empire into fix circles was eftablifhed by Maximilian I. in 1500, at Augfburg; twelve years afterwards he divided it afrefh, into ten circles; which partition was confirmed by Charles V. at the diet of Nuremberg, in 1522.

Though the order of thefe circles has never been well regulated; yet, in the imperial matricula, it is as follows: the circle of Auftria, that of Burgundy, that of the Lower Rhine, and that of Upper Saxony, which were the circles added in 1512; thofe of Bavaria, Franconia, Suabia, Upper Rhine, Weftphalia, and the Lower Saxony, the fix that were firft eftablifhed. Each circle, according to the laws of the empire, had its directors or fummoning princes, and its commanding officer under the title of captain, colonel, or field marfhal, &c. It was the province of the firft to convoke affemblies of the ftates of each circle, and to direct and fuperintend its concerns; and the latter had the command of the troops, and the care of the artillery and neceffary ammunition in each circle. The ftates of each circle were required to contribute to the exigencies of the empire, of which they were members, by a tax impofed on them for maintaining the troops and defraying other expences, in proportion to the number of horfe and foot, and other neceffary occafions.

CIRCLES *of judgment*, in *Antiquity*, were ancient monuments of the Runic kind, confifting of upright ftones, found in all the Danifh dominions, in Holftein, Slefwic, Jutland, the ifles, Norway and Iceland; and alfo in Sweden. They feem to have been erected at different ages; fome are more ancient than the 11th century, and others as recent as the 15th. The druidical circles in Britain claim a much higher antiquity. See DRUID.

CIRCOCELE. See CIRSOCELE.

CIRCOLO *mezzo*, in the *Italian Mufic*, is a diminution of four quavers or femiquavers, or notes of equal value, which reprefent a femicircle proceeding by conjoint degrees.

CIRCON, in *Mineralogy*. See ZIRCON.

CIRCUIT, in French *circuit* or *enceinte*, in *Fortification*, is the wall or rampart of ftone or earth, or partly of both, or the dike, ditch, &c. which furrounds or enclofes any city, town, place, or fpot of ground. This term is alfo applicable to the line or lines, which form the perimeter of any, being fynonymous thereto.

CIRCUIT, or CIRCUITY, in *Law*, a longer courfe of proceeding, to recover the thing fued for, than is needful.

Thus, if a man grant a rent-charge of 10 *l.* out of his manor, and after, the grantee diffeifeth the grantor of the fame manor, who brings an affife, and recovers the land, and 20 *l.* damages; which being paid, the grantee brings his action for 10 *l.* of his rent, due during the time of the diffeifin, and which he muft have had, if no diffeifin had been: this is called *circuity of action;* becaufe, as the grantor was to receive 20 *l.* damages, and to pay 10 *l.* rent, he might have received 10 *l.* only for damages, and the grantee have kept the other 10 *l.* in his hands, by way of retainer for his rent, and fo faved his action, which appears to be needlefs. Terms de Ley.

CIRCUIT is alfo the journey or progrefs the judges take, twice every year, through the feveral counties of England and Wales (except as in the cafes ftated under *General* ASSISES), to hold courts, and adminifter juftice, where recourfe cannot fo well be had to the king's courts at Weftminfter.

Thefe were firft eftablifhed, with fome little difference, by Henry II.; who, with the advice of a great council of his prelates, earls, and barons, at Northampton, A.D. 1176, divided the whole kingdom into fix parts, or circuits, and appointed three judges, learned in the law, to hold courts in each of thefe, by a commiffion from the king, empowering them to hear and determine all caufes not exceeding the value of one-half of a knight's fee, unlefs the matter was of fuch importance or difficulty, as to require the judgment of the king's court in his royal prefence. Thefe juftices itinerant took an oath, to adminifter juftice to all perfons with impartiality. They had alfo authority to judge in all criminal caufes and pleas of the crown, and to tranfact a variety of other affairs for the public good. A fmall change was made in this excellent inftitution, A.D. 1179, by dividing the kingdom into four circuits, and allowing a greater number of judges to each of thefe circuits. It is eafy to conceive how great a check the circuits of thefe judges, of fuperior rank, knowledge, and integrity, muft have given to the wantonnefs and partiality of the inferior courts, and how great an advantage they were to the people, by bringing juftice within their reach. It muft, however, be confeffed, that though the honour of bringing this wife inftitution to a fettled ftate is due to Henry II., there is fufficient evidence that courts were held, occafionally at leaft, by itinerant judges in more ancient times. Madox, Hift. Excheq. p. 86—88. See JUSTICES *in eyre*.

Thefe were afterwards exprefsly ordained by *Magna Charta;* which, befides prohibiting all denials or delays in the adminiftration of juftice, fixed the court of common pleas at Weftminfter, that the fuitors might be no longer haraffed with following the king's perfon in all his progreffes; and at the fame time brought the trials of iffues home to the very doors of the freeholders, by directing affifes to be taken in the proper counties, and eftablifhing annual circuits.

Thefe circuits are now ufually made in the refpective vacations after Hilary and Trinity terms; affifes being allowed to be taken in the holy time of Lent by confent of the bifhops at the king's requeft, as expreffed in ftatute Weftm. 1. 3 Edw. I. c. 51. See *General* ASSISES and JUSTICES *of Affife*. The feveral counties of England are divided into fix circuits: viz. 1. *Midland;* containing the counties of Northampton, Rutland, Lincoln, Nottingham, Derby, Leicefter, Warwick. 2. *Norfolk;* including Bucks, Bedford, Huntingdon, Cambridge, Norfolk, Suffolk. 3. *Home;* comprehending Hertford, Effex, Kent, Suffex, Surrey. 4. *Oxford;* containing Berks, Oxford, Hereford, Salop, Gloucefter, Monmouth, Stafford, Worcefter. 5. *Weftern;* including Southampton, Wilts, Dorfet, Cornwall, Devon, Somerfet. 6. *Northern;* comprehending York, Durham, Northumberland, Cumberland, Weftmorland, Lancafhire. Two judges are appointed to each circuit. In Wales there are two circuits, viz. North and South Wales. In Scotland there are three circuits, viz. South, Weft, and North, which the lords of jufticiary go twice a year, *viz.* in May and October, for trial of crimes only: though, by a recent ftatute, they have an appellate jurifdiction in civil cafes under 12 *l.* See JUSTICIARY.

CIRCUIT, *electrical,* denotes the courfe of the electric fluid from the charged furface of an electric body, to the oppofite furface into which the difcharge is made. Some of the firft electricians apprehended, that the fame particles of the electric fluid which were thrown on one fide of the charged glafs, actually made the whole circuit of the intervening conductors, and arrived at the oppofite fide; whereas Dr. Franklin's theory only requires, that the redundancy of electric matter on the charged furface fhould pafs into the bodies, which form that part of the circuit which is contiguous to it, driving forward that part of the fluid which they naturally poffefs, and that the deficiency of the exhaufted furface fhould be fupplied by the neighbouring conductors, which form the laft part of the circuit. On this fuppofition, a vibrating motion is fucceffively communicated through the whole length of the circuit. This circuit is always formed of the beft conductors, let the length of it be ever fo great. Many attempts were made both in France and England, at an early period in the hiftory of electricity, to afcertain the diftance to which the electric fhock might be carried, and the velocity of its motion. The French philofophers, at different times, made it to pafs through a circuit of 900 toifes, and even of 2000 toifes, or about two Englifh miles and a half; and they difcharged the Leyden phial through a bafon of water, the furface of which was about an acre. And M. Monnier found, that, in paffing through an iron wire of 950 toifes in length, it did not fpend a quarter of a fecond: and that its motion was inftantaneous through a wire of 1319 feet. In 1747, Dr. Watfon, and other Englifh philofophers, after many experiments of a fimilar kind, conveyed the electric matter through a circuit of four miles; and they concluded from this and another trial, that its velocity is inftantaneous, or, as we may fuppofe, too rapid to be meafured. Prieftley's Hift. of Electricity, vol. i. fect. 2. p. 128. 8vo. ed. 1775. See ELECTRICAL *fhock*.

CIRCUITORES. See AGONISTICI.

CIRCULAR, any thing that is defcribed, or moved in a round; as the circumference of a circle, or the furface of a globe. The circular form is of all others the beft difpofed for motion, and the moft capacious. The modern aftronomers fhew, that the heavenly bodies do not move in circular, but in elliptic orbits. See PLANET, &c.

CIRCULAR *Arcs*. See ARCH.

CIRCULAR *Inftrument of Reflection*, or *Multiplying Circle*, in *Navigation*. See CIRCLE.

CIRCULAR *Letter*, a letter directed to feveral perfons, who have the fame intereft in fome common affair: as in the convocation of affemblies, &c.

CIRCULAR *Lines*, an appellation given by fome to fuch ftraight lines as are divided by means of the divifions made in the arc of a circle. Such are SINES, TANGENTS, SECANTS, &c.

CIRCULAR *Numbers*, are fuch whofe powers end in the roots themfelves; as 5, whofe fquare is 25, and cube 125. See NUMBER.

CIRCULAR *Parts*, *Neper's*, or *Napier's*, are the complements of the two oblique angles of a right-angled fpherical triangle, the complement of the hypothenufe, and the two legs, by having any two of which the third is known.

Napier, in his treatife, entitled, "Logarithmorum Canonis Defcriptio," gave a general rule, with regard to thefe circular parts, which is as follows: *viz.* "The rectangle under the radius, and the fine of the middle part, is equal to the rectangle under the tangents of the adjacent parts, and to the rectangle under the cofines of the oppofite parts." The right-angle, or quadrantal fide, being neglected, the two fides, and the complements of the other three parts, are called the circular parts, becaufe they follow each other, as it were, in a circular order. If any one of thefe be fixed upon as the middle part, thofe that are next to it are the adjacent, and thofe that are fartheft from it are the oppofite parts. This excellent rule, concife and yet comprehenfive, includes all the particular rules for the folution of right-angled fpherical triangles, and may be eafily applied to oblique fpherical triangles, by letting fall a perpendicular, thofe two cafes excepted in which either the three fides or the three angles are given; and for thefe a fimilar expedient has been devifed by lord Buchan and Dr. Minto. M. Pingré, in the "Memoires de Mathematique et de Phyfique," for 1756, reduces the folution of all the cafes of fpherical triangles to four analogies; which, in reality, are Napier's circular parts, under another form, together with his fecond or fundamental theorem, applied to the fupplemental triangle. Thefe analogies are very difficult to be retained in the memory; and, therefore, Napier's rule, which is fo eafily remembered, ought to be preferved under its prefent form. Indeed, it cannot be eafily forgotten,

forgotten, provided that one circumſtance be regarded; *viz.* that the ſecond letters of the words "tangents" and "coſines" are the ſame with the firſt of the words "adjacent" and "oppoſite." Moreover, the rule for reſolving the two caſes of ſpherical triangles, to which the former rule is inapplicable, may be thus expreſſed: "Of the circular parts of an oblique ſpherical angle, the rectangle under the tangents of half the ſum and half the difference of the ſegments at the middle part (formed by a perpendicular drawn from an angle to the oppoſite ſide) is equal to the rectangle under the tangents of half the ſum and half the difference of the oppoſite parts." By the circular parts of an oblique ſpherical triangle are meant its three ſides and the ſupplements of its three angles. Any one of theſe ſix being aſſumed as a middle part, the oppoſite parts are thoſe two of the ſame denomination with it; *e. g.* if the middle part is one of the ſides, the oppoſite parts are the other two; and if the middle part is the ſupplement of one of the angles, the oppoſite parts are the ſupplements of the other two. Farther, ſince every plane triangle may be conſidered as deſcribed on the ſurface of a ſphere of an infinite radius, theſe two rules may be applied to plane triangles, provided that the middle part be reſtricted to a ſide. Thus it appears, ſays lord Buchan, in his "Life of Napier," that two ſimple rules ſuffice for the ſolution of all the poſſible caſes of plane and ſpherical triangles. Theſe rules, from their neatneſs, and the manner in which they are expreſſed, cannot fail of engraving themſelves deeply on the memory of every one who is a little verſed in trigonometry. It is a circumſtance, he adds, worthy of notice, that a perſon of a very weak memory may carry the whole art of trigonometry in his head. See PART, TRIANGLE, and TRIGONOMETRY.

CIRCULAR *ſailing*, the method of navigating a ſhip upon the arch of a great circle of the globe. See GREAT CIRCLE SAILING.

This mode of ſailing has been theoretically recommended, becauſe the neareſt diſtance between two places on the globe is the arc of a circle, and becauſe it is of importance that a ſhip ſhould arrive at its deſtined port by the ſhorteſt courſe. As in Mercator's ſailing, the ſolution of caſes is performed by plane triangles, ſo in this method of ſailing caſes are reſolved by means of ſpherical triangles; but theſe latter ſerve rather for exerciſes in the ſolution of ſpherical triangles than for any uſeful purpoſes of navigation. See SAILING.

CIRCULAR *ſcale.* See SCALE.

CIRCULAR *ſegment, reſiſtance of.* See RESISTANCE.

CIRCULAR *ſpots* are made on pieces of metal by large electrical exploſions. See experiments and obſervations upon them in Dr. Prieſtley's Hiſtory of Electricity, vol. ii. ſect. 9. ed. 8vo. and Phil. Tranſ. vol. lviii. p. 68.

Theſe beautiful ſpots, produced by the moderate charge of a large battery diſcharged between two ſmooth ſurfaces of metals, or ſemi-metals, lying at a ſmall diſtance from each other, conſiſt of one central ſpot and ſeveral concentric circles, which are more or leſs diſtinct, and more or fewer in number, as the metal upon which they are marked is more eaſy or difficult of fuſion, and as a greater or leſs force is employed. They are compoſed of dots or cavities, which indicate a real fuſion. If the exploſion of a battery, iſſuing from a pointed body, be repeatedly taken on the plain ſurface of a piece of metal near the point, or be received from the ſurface on a point, the metal will be marked with a ſpot, conſiſting of all the priſmatic colours diſpoſed in circles, and formed of the ſcales of the metal ſeparated by the force of the exploſion.

CIRCULAR *velocity*, a term in *Aſtronomy*, ſignifying the velocity of a planet, or revolving body, which is meaſured by the arch of a circle; as ſuppoſe by A B, *Plate, Aſtronomy, fig.* 11.) deſcribed on the centre of attraction S.

The circular velocity of a body moving from B to C is meaſured by the arc B C.

CIRCULAR *winding-ſtairs.* See STAIRS.

CIRCULATING DECIMALS. See REPETEND.

CIRCULATION, the act of moving round, or in a circle. See the following articles.

CIRCULATION *of the blood*, in *Anatomy*, is the courſe which this fluid purſues in the heart and lungs, and in the blood-veſſels of the body. This courſe is very juſtly named a circulation, inaſmuch as the blood is always paſſing round in the ſame track, and its motion conſtantly tends to the point from which it began.

The word *circulation*, when uſed abſolutely, comprehends the whole courſe of the blood, as well in the lungs as in the arteries and veins of the body at large.

The *greater circulation* is the paſſage of the blood from the left ſide of the heart, through the arteries, to the extremities of the body, and its return through the veins to the right ſide of the ſame viſcus.

The *leſſer circulation* is the tranſmiſſion of the blood from the right to the left ſide of the heart, through the lungs.

The uſes of the blood in the animal economy are ſo numerous and important, that every circumſtance relating to its properties, or to the laws of its motion, cannot be too carefully inveſtigated by the phyſiologiſt and practitioner.

By filling the veſſels with ſubtle fluids after death, it appears that the blood is copiouſly diſtributed to every part of the ſyſtem, at leaſt with a very few exceptions, as the inſenſible coverings of the body, the ſubſtance of the teeth, &c. and common experience muſt have convinced every perſon of the ſame fact, for hardly any part can be wounded with the point of the fineſt needle without a flow of blood being produced. This fluid does not, however, as the ancients thought, move backward and forward in one order of veſſels, but is carried, in a circulatory courſe, from the heart to all parts of the body by the arteries, and is thence returned to the ſame part by the veins.

In a ſyſtematic account of this ſubject, we ſhould firſt conſider the ſtructure of the heart and blood-veſſels, and the powers by which they are enabled to receive and to propel the blood, we refer the reader for a more complete account of theſe points to the articles HEART, ARTERY, VEIN.

The arteries receive the blood from the heart, and diſtribute it to all parts of the body. Theſe veſſels are in general leſs capacious than the veins, but of a more ſolid and compact texture; they are highly elaſtic, and probably poſſeſſed of conſiderable muſcular powers. All the arteries of the body are derived from one of two trunks: 1ſt, the pulmonary artery, which, ſpringing from the right ventricle, ramifies through the lungs; 2dly, the aorta, which, commencing from the left ventricle, is diſtributed over the whole body. The arteries, after their various ramifications and anaſtomoſes, terminate by communicating with the origins of the veins; ſo that the blood returns towards the heart in a continuous canal, in which there are no obvious marks of diſtinction to define the limits between the two orders of veſſels.

The ſtructure of the veins ſoon becomes clearly diſtinguiſhed from that of the arteries; they poſſeſs no muſcularity; they are much more capacious; leſs conſtant in their courſe and diviſions; weaker in their texture; and leſs elaſtic than the latter veſſels. They are alſo generally characterized by the poſſeſſion of valves, which prevent the return of blood towards their extremities. There are ſeven large venous trunks opening into the two auricles of the heart. The ſuperior and inferior venæ cavæ return the blood from the

the upper and lower parts of the body to the right or anterior auricle; the coronary vein pours into the ſame cavity that which has circulated through the ſubſtance of the heart itſelf. The two right and two left pulmonary veins diſcharge, into the left or poſterior auricle, the blood which has paſſed through the lungs.

The heart is placed in the centre of the ſanguiferous ſyſtem, and is endowed with great muſcular power, by which it is enabled to diſtribute and circulate the blood through the two orders of veſſels which we have now deſcribed. The trunks of the circulating tubes meet together in this part, which is the firſt mover of the whole animal frame, and ſuſtains, by a perpetual and truly wonderful power, this primary vital function, from the ſecond or third week after conception to the laſt period of our exiſtence.

This organ alternately receives and propels the blood. That which has circulated through the body enters the right auricle by the ſuperior and inferior venæ cavæ; the coronary vein pours into the ſame cavity the blood which has ſupplied the heart itſelf. The right auricle propels this, which is venous blood, through the anulus venoſus into the right or pulmonary ventricle, and it goes from this cavity to circulate through the lungs by the pulmonary artery. It is again brought to the heart by the four pulmonary veins, which open into the left auricle. It becomes changed from the ſtate of venous to that of arterial blood, by the expoſure to the atmoſpheric air, which takes place in its circulation through the lungs; for an account of which change ſee Respiration. From the left auricle it paſſes through the left anulus venoſus, into the ventricle of the ſame ſide, and is thence expelled by the aorta into the arterial ſyſtem of the whole body. From the minute arteries it enters the origins of the venous ſyſtem, and is again poured into the heart by the three venous trunks, which we have already mentioned.

This paſſage of the blood through the cavities of the heart is regulated and maintained in an undiſturbed ſucceſſion by valves placed at the different openings, which prevent all reflux of the circulating fluid. See the account of the *ſtructure of the* Heart.

Having thus deſcribed the courſe of the blood, we think it right to ſubjoin the proofs and experiments on which it is ſupported; although the fact of the circulation has been ſo long admitted, and is now ſo generally eſtabliſhed, that the enumeration may to ſome perſons appear ſuperfluous.

The courſe of the blood through the heart, *i. e.* from the right auricle to the left ventricle, by the medium of the lungs, is manifeſt from the ſtructure of the heart itſelf. The valves, which are placed at its various apertures, actually will not admit of the blood's motion in any other direction than what we have deſcribed.

That the blood paſſes from the heart into the trunk of the aorta, thence into its branches, and ſo on to the moſt minute ramifications, is evinced: 1ſt, by the effect of ligatures on theſe veſſels: the artery becomes turgid between the heart and the ligature, and empty between the ligature and its diſtribution. 2dly, By opening an artery, when tied, above and below the ligature: the blood in this caſe flows only from the opening which is neareſt to the heart. 3dly, By ocular teſtimony: the paſſage of the blood can be ſeen with the aid of glaſſes in frogs, fiſhes, &c.

The paſſage of the blood through the veins, in a contrary courſe to that, in which it flows along the arteries, *i. e.* from the minute ramifications towards the trunks, and thence to the heart, is proved; 1ſt, By the ſtructure and diſpoſition of the valves, which afford an invincible impediment to all retrograde motion. 2dly, By ligatures on theſe veſſels, which make the vein turgid between the extremities of the body and the ligature, and empty in the reſt of its courſe. 3dly, By opening a vein, when tied, above and below the ligature. 4thly, By microſcopical obſervation in the lower animals.

The paſſage of the blood from the arteries into the veins ſeems to flow as a corollary, from what we have ſtated concerning the proofs of its courſe in theſe two ſyſtems of veſſels. We have ſhewn that the ultimate arteries are continuous with the origins of the veins; that the blood moves from the heart to the extremities in the former veſſels, and that it paſſes from the extremities to the heart in the latter. The intermediate paſſage is a direct conſequence of theſe facts. But it may be demonſtrated by inconteſtible proofs independently of this argument. If we tie the artery of a part, its correſpondent vein receives no blood; if we take off the ligature, the vein is again filled. The quantity of blood expelled from the aortic ventricle is ſo conſiderable, that the ſupply can only be kept up by a return of this blood to the heart. We calculate that two ounces of blood are expelled from the heart at each pulſation; if we ſuppoſe eighty pulſations in a minute, 9600 ounces will be thrown into the aorta in an hour, and 14400 lbs. in a day. The ſame blood therefore which the aorta received from the heart muſt return to this viſcus; and the only paſſage by which it can return is through the veins. Nearly the whole blood of the body will be diſcharged from a wound of a ſingle artery or vein. Laſtly, the paſſage of the blood from the arteries into the veins may be proved by the direct teſtimony of the ſenſes in living animals. The uſe of the microſcope affords this proof in the tranſparent parts of cold-blooded animals, as the meſentery and web of the foot in frogs, the tail of fiſhes, &c.

The motions of any part of the heart, conſidered ſingly and individually, conſiſt in a conſtant ſeries of alternate contractions and dilatations; or, as they are technically named, alternate ſtates of *ſyſtole* and *diaſtole.* The contractions take place as in any other muſcles; the dilating cauſe conſiſts in the forcible entrance of blood into the cavity. The auricles and ventricles, when viewed in relation to each other, are ſucceſſively contracted and dilated; the correſponding parts acting at the ſame time on both ſides of the heart. Thus, when the auricles contract, in order to expel the blood which they have juſt received from the ſyſtem at large, and from the lungs, the ventricles are relaxed, and therefore in a ſtate fit for receiving this blood. When, in the following moment, the recently filled ventricles contract, in order to urge forwards the blood into the two arterial trunks, the auricles are relaxed, and become immediately diſtended by the current of venous blood. The action of the heart, and of the veſſels connected with it, may therefore be diſtributed into ſucceſſive periods. In the firſt of theſe, the venæ cavæ and pulmonary veins pour their blood into the two auricles, and thus cauſe a diaſtole of theſe cavities. The ſyſtole of the auricles tranſmits the blood into the ventricles in the ſecond period; and theſe latter cavities expel their contents into the arteries in the third portion of time. Thus the action of the veins takes place at the ſame point of time with that of the ventricles; and the contraction of the auricles is ſynchronous with that of the arteries.

The ſyſtole of the ventricles, which is ſuppoſed to occupy one third of the time of the whole pulſation of the heart, is accompliſhed by an approximation of the ſides of the cavities to the middle partition, and of the apex to the baſis of the heart. The whole viſcus by this means becomes ſhorter and more obtuſe. The well known fact of the heart's ſtriking againſt the left breaſt in its contraction, may ſeem on the firſt glance to refute this account of the ſyſtole of the ventricles. But, on a further examination, it can have no ſuch effect; ſince

ſince the phenomenon in queſtion depends on two cauſes amply ſufficient to produce the effect, which have been long ago explained by Ferrein and Senac. (See Queſtiones Medicæ, 12.—Monſpelii, 1732.—Anatomie de Heiſter avec des Eſſais de Phyſique. Traité de la Structure du Cœur, tom. i p. 354, et ſeq.) The ſwelling of the auricles, which are at the back of the heart, and particularly of the left auricle, which is interpoſed between the ſpine, and the baſe of the left ventricle, neceſſarily cauſes the point of the heart to advance towards the ſide; and this motion may be imitated in the dead body by injecting or inflating the auricles. The other cauſe conſiſts in the connection of the large arteries, particularly of the aorta, with the baſe of the heart. A curved and flexible tube, when ſuddenly diſtended, becomes in ſome meaſure ſtraightened. Thus when the blood is impelled into the aorta, the curve of that veſſel approaches more nearly to a ſtraight line. Its poſterior end being firmly attached to the vertebræ, is immoveable; to its anterior and moveable part is fixed the heart, which, by the ſtraightening of the veſſel, is obliged to deſcribe a portion of a circle, in doing which the apex ſtrikes againſt the ſide. Theſe two circumſtances occur ſimultaneouſly; the venous blood ruſhes into the auricles, at the ſame time that the contraction of the ventricle fills the aorta.

The impulſe of the blood expelled by the ſyſtole of the aortic ventricle is felt in the whole arterial ſyſtem; and it produces, in all arteries which come within the ſphere of the touch, and which have an area of not leſs than one ſixth of a line in diameter, an obvious and perceptible effect, called the pulſe, which is a real ſtate of diaſtole of the artery, and which is aſcertained to correſpond exactly, and to be perfectly ſynchronous with the ſyſtole of the heart. The number of pulſations in a given ſpace of time varies infinitely in healthy perſons. Age is the chief cauſe of theſe varieties: but other circumſtances, which conſtitute the peculiar ſtate of health of each individual, have conſiderable effect; ſo that no ſtandard can be ſettled which ſhall prove generally correct. The following numbers afford, we believe, as near an approximation as can be expected amidſt ſo much uncertainty; they will ſerve at leaſt as a comparative view in ſubjects of different ages.

The heart of an infant, ſleeping tranquilly, performs, in the firſt days of exiſtence, about 140 pulſations in a minute. At the end of the firſt year the pulſations are in the ſame ſpace of time about 124:

At the end of the ſecond year	110
——— third and following years	96
——— ſeventh and following	86
——— time of puberty	80

beyond which time the variations are very great.

The female ſex are obſerved, *cæteris paribus*, to have a more frequent pulſe than the male; and ſhort perſons exceed tall ones in this reſpect. It is alſo remarked, that the inhabitants of cold climates have ſlow pulſes. It is moſt familiarly known that the pulſe is accelerated by taking a meal, by the act of coition, by exerciſe of the body, or affections of the mind. The latter cauſes, indeed, if carried to a conſiderable extent, produce moſt vehement palpitations of the heart. In ſaying thus much of the pulſe, we have thought it more natural to refer it to the heart, which is its ſource, than to the arteries, in which it is commonly examined.

It has been queſtioned, whether the heart expels the whole of the contained blood in its ſyſtole. It ſeems probable that this is the caſe in a healthy animal; although it has been denied on the faith of experiments. We muſt be cautious in applying inferences, drawn from the interrupted and diſordered action of the heart of an animal, expiring under the torture of an experiment, to the living functions of the viſcus. If any blood remains in the ventricle, it excites a conſtant contraction of the cavity. In ſome cold-blooded animals, and in the incubated chick, the heart is obſerved to become completely pale in its ſyſtole, which proves an entire evacuation of the ventricles.

The pulſations of the heart proceed in a regular and continued ſucceſſion to the laſt period of life: and then all its parts do not ceaſe to act at once. But the right auricle and ventricle ſurvive the oppoſite cavities for ſome little time; ſo that the former part has been called the *ultimum moriens*. The blood which returns by the venæ cavæ, after the laſt expiration, no longer finds the uſual paſſage through the lungs, which are contracted, but it is ſtill urged on from behind by that which the aorta has recently propelled. Hence, it is forced into the right auricle, and excites contraction in that part by the ſtimulus of its preſence, ſome time after the left ſide has been at reſt. This congeſtion on the right ſide of the heart in the laſt agony, explains the empty ſtate of the arteries, particularly the larger ones, after death. Sabatier has aſcribed to the ſame cauſe, the greater relative capacity of the right ventricle and auricle of the adult heart. (See Mémoire ſur l'inégale capacité des cavités du cœur, et des vaiſſeaux pulmonaires, in his Traité complet d'Anatomie, tom. iii.) The appearance, which we are now alluding to, does not admit of explanation from any circumſtances connected with the healthy functions of the heart and lungs; yet Sabatier's ſtatement can hardly be received as completely ſatisfactory. For, not to mention that we ſeldom find theſe cavities actually diſtended, this explanation ſuppoſes the veins to pour the blood into the heart, with greater force than the ventricle can exert in reacting; which does not appear probable from comparing the ſtructure of the two parts. The facts, however, contained in the memoir above-mentioned deſerve attention: it is ſtated that, by opening the venæ cavæ, and tying the aorta, which prevents accumulation of blood on the right, and cauſes it on the left ſide of the heart, the left cavities will be found after death to exceed the capacity of the right. This experiment would have been more convincing, had the difference been aſcertained with certainty and correctneſs, inſtead of reſting on the inaccurate ground of a mere inſpection.

The longer duration of action in the right, than in the left cavities of the heart, is to be aſcribed ſolely to the circumſtance of the former parts continuing to receive blood, after the latter are completely evacuated. Hence, if an experiment be inſtituted, in which theſe conditions ſhall be reverſed; the prerogative of *ultimum moriens* will be transferred to the left cavities. Haller has produced this effect: he opened the venæ cavæ, preſſed out the blood from the right cavities, and tied thoſe veins. He made a large aperture in the pulmonary artery, in order to evacuate more completely the right ventricle. The pulmonary veins were left untouched; but the aorta was tied. Thus the right auricle and ventricle were evacuated, while the blood was received and retained in the oppoſite cavities. By this means the right auricle and ventricle remained in action, long after all contraction of the left cavities had ceaſed. See Elementa Phyſiologiæ, lib. iv. ſect. 5. § 14.

It is hardly poſſible to determine the velocity of the blood's motion in the healthy ſtate; for individuals differ from each other in this reſpect; and conſiderable variety probably takes place in different parts of the body. It is generally

generally ſuppoſed, that the blood flows in a more gentle ſtream through the ſmall arteries than in the arterial trunks; and that the velocity of its current is ſomewhat leſs in the veins, than in the arteries of the body. Theſe differences have, however, been exaggerated by former phyſiologiſts. The mean velocity of the blood in the aorta is calculated at eight inches for each pulſation; which gives about 50 feet in a minute. If we reflect that the ſyſtole of the ventricle, which gives this whole impulſe to the blood, occupies only one third of the whole pulſe, the velocity of the blood's motion muſt be trebled in that diviſion of the time. It is ſaid that this velocity, which we have aſſigned to the blood's motion at its departure from the heart, becomes ſpeedily diminiſhed in its further progreſs; and the diminution has been deduced from various cauſes. The firſt and moſt powerful of theſe is the conſtantly increaſing area of the branches, when compared with the trunk of an artery. See Artery.

It is a well known law in hydraulics, that the velocity of a fluid paſſing through an inverted cone conſtantly decreaſes, and that the diminution of velocity is in the ratio of the increaſe of area. The mathematical phyſiologiſts have alſo noticed the effects of friction; deducing theſe from a compariſon with the courſe of fluids in dead tubes. Other cauſes have been deduced from the ſame ſource; hence the ſerpentine courſe of ſome arteries, the unfavourable angles by which they ſometimes ariſe, and their communications with each other are enumerated among the circumſtances, which retard the courſe of the arterial blood. But it muſt be remembered, that in viewing theſe retarding cauſes, we are conſidering their action on the blood, as if this fluid were contained in inanimate tubes; and influenced merely by the contraction of the heart; without taking into account any acceſſory impulſe, which may be, and moſt probably is, derived from the arteries. This retardation has been variouſly eſtimated by different calculators; who have all made it very conſiderable. Hales ſuppoſes the blood to flow through the capillary arteries of a frog, at the rate of two-thirds of an inch in a minute; which will be about 650 times ſlower than in the human aorta. ("Statical Eſſays," vol. ii. p. 66.) Robinſon and Whytt have gone ſtill farther; the former ſtating that the velocity of the blood's motion in the aorta, is to that in the ſmalleſt veſſels, as 1100 to 1. ("Diſſertation on the Food and Diſcharges of Human Bodies.") We mention theſe calculations to ſhew what abſurdities have been committed by men of the greateſt abilities, when they have applied the laws which regulate the properties of dead matter to the living functions of the animal machine. Haller's "Obſervations on the Circulation in living Animals," entirely overthrow theſe calculations. ("Elementa Phyſiologiæ," lib. 6. ſect. i. § 30.) He found by his microſcopical experiments, that the blood flowed generally as rapidly through the ſmall as through the larger veſſels. He ſtates alſo, that in living animals it is poured out as far from a ſmall as from a large artery. The numerous and diverſified experiments of Spallanzani, afford additional evidence of the ſame truth, and throw conſiderable light on the whole ſubject. The reſults of his experiments are ſo concluſive, that we preſent them to the reader in his own words: "I did not find that the blood, in paſſing out of the middle-ſized arteries into their branches, experienced the leaſt retardation from any difference in the capacity of theſe veſſels, or the numerous angles which they formed with one another; neither did the mode of the circulation, whether languid or ſtrong, oſcillatory or intermittent, appear to be at all affected by the multiplicity of natural and artificial curvatures, or the flexures and convolutions made by the different ramifications. When the ſtrength of the animal was not impaired, the blood in the ſmall arteries moved very rapidly, and with nearly an equal velocity; but when, on the contrary, it had been exhauſted, or in an unhealthy ſtate, the circulation was carried on with the ſame celerity in the middle ſized arteries; whilſt it began to abate in the ſmall arterial ramifications, and ſtopped ſooner or later in proportion to their diſtance from the heart. The united reſults of theſe experiments diſplay, in a ſtriking point of view, the true motion of the blood from the origin to the termination of the arteries, which was hitherto only conjectural, and ſubject to frequent diſputes, from the want of a ſufficient number of experiments. Theſe facts, beſides, confirm the ſage maxim of Haller, reſpecting the caution with which we ought to apply mechanical principles to the animated ſyſtem; for, in fact, if the animal machine be ſtrictly ſubject to hydraulic laws, why do they not produce the ſame effects in the vaſcular ſyſtem, as in common tubes? Whilſt, however, we acknowledge that theſe laws muſt exert an influence upon the phenomena of the circulation, we contend that their power is counterbalanced by oppoſite cauſes, inherent in the ſanguiferous ſyſtem." ("Experiments upon the Circulation of the Blood throughout the Vaſcular Syſtem, by the Abbé Spallanzani," p. 259.)

We have ſtated, that the blood is thrown into the arteries, by ſeparate contractions of the heart; yet theſe veſſels are conſtantly full, as may be proved by opening them during the heart's diaſtole. For the blood flows on in ſuch a way, that the ſubſequent quantity diſcharged from the right ventricle, overtakes that which is before, and thus cauſes the pulſation of the arteries. The exceſs of velocity in the blood, coming from the heart, over that contained in the arteries, becomes conſtantly leſs; and at a certain point ceaſes altogether. Here the pulſe ceaſes alſo. Hence in microſcopical obſervations on the courſe of the blood in ſmall veſſels, its ſtream appears to be uniform: and it is commonly ſtated, that the pulſation ceaſes in veſſels of about one-ſixth of a line in diameter.

The motion of the blood in the minute veins, ſeems to be equal in velocity to its courſe in the ſmall arteries; this velocity increaſes in the larger trunks; and there is a conſtant acceleration in the blood's courſe until it arrives at the heart. This fluid is paſſing through tubes which conſtantly decreaſe in area; and it follows of neceſſity, that by diminiſhing the channel of a fluid, its courſe muſt be accelerated. Hence the trunks of the venæ cavæ return to the heart, within a given time, as much blood, as the aorta carried out of this viſcus.

The motion of the blood along the veins muſt be derived from the impulſe, which it receives from the heart, and from the action (if there be any) of the arteries. Its circulation in theſe veſſels is aided by the contraction of the muſcles, which muſt urge on the contained fluid towards the heart; ſince their valves prevent any retrograde motion.

The return of the venous blood is affected by reſpiration. It appears in living animals, that the large veins become turgid during expiration; either from the obſtruction of the blood's courſe through the lungs, or in conſequence of its reflux from the heart; they are evacuated in inſpiration. In this latter ſtate the depletion of the veins cauſes the brain to ſubſide; whereas in expiration the retention of the blood produces diſtention and ſwelling of the viſcus.

As the motion of the blood in the veins is not derived from any immediate force, it is conſiderably affected by gravity; in ſpite of the valves, which counteract this influence conſiderably. The experiments of Haller and Spallanzani have ſhewn this fact in cold-blooded animals. It is evinced alſo

also by various phenomena in the human subject; viz. varices of the legs, swelling of the feet after the erect position has been long preserved, &c.

Some very curious and interesting phenomena have been observed in experiments on living animals, and referred to a general principle termed derivation; in conformity with which it appears that the blood flows rapidly towards any quarter, from which the usual pressure is removed. The experiments of Haller and Spallanzani have much illustrated this subject, which is of the greatest importance in a practical view. (See Haller's "Elementa Physiologiæ," lib. 6. sect. 1. § 40. Spallanzani's "Experiments on the Circulation, &c." p. 386, et seq.) The blood rushes from all quarters towards an incision in a vein or artery; it forsakes the neighbouring trunks and branches; it is discharged both in the direction of the circulation, and in a retrograde course; it moves against the force of gravity, as well as contrary to its usual current. When the blood stagnates in an animal submitted to experiment, it flows again through an opening made in an artery or vein. The blood in the artery, corresponding to the vein that is opened, recovers or accelerates its course according to the stagnation or velocity which it possessed before the operation. An incision into the heart has the same effect; the blood flows out at the opening both from the arteries and veins. The swelling of a part under a cupping glass is probably derived from the principle which we have now described.

When the circulation ceases before death, it appears to stop first in the small vessels; and this stagnation is propagated towards the heart. "The arterial blood," says Spallanzani, in speaking of the phenomena of languid circulation, "which at first had an uniform course, lost more or less quickly its equilibrium, and abated in velocity at each diastole of the heart; to this abatement soon succeeded a complete stagnation, except during the systole, when the blood preserved some remains of motion, which however disappeared by degrees. Thus the circulation ceased in the arteries by a successive and gradual diminution of momentum, without any flux or reflux, intermittent or vibratory motion. The motion of the blood in the veins, ceased in the same gradual manner; and these different phenomena were alike evident in the arterial and venous fluid of cold and warm-blooded animals." P. 383.

It has been stated that the globules of the blood pass more in the axis of the vessel than the other parts of this fluid. This circumstance has been deduced from an absurd application of the laws of hydraulics to the circulation, and is not founded on any actual observation in living animals.

It appears also, from experimental inquiries on the subject, that we are not warranted in assigning to the blood any intestinal motion, in addition to the regular and uniform progression, which we have been now describing. Yet it is not unlikely, that the various directions, divisions, and anastomoses of the blood-vessels may have some influence on the elements of the blood.

We proceed to consider the powers, which animate the organs of circulation, and enable these parts to execute their several functions. Those of the heart, as being the greatest and most important, will claim our first attention; but there are secondary and auxiliary forces, which probably have considerable share in aiding the actions of this viscus.

We shall readily perceive, that no certain calculation can be formed of the powers of the heart, when we consider that neither the quantity of blood expelled at one pulsation, nor the distance through which it passes in a given time; nor the velocity of its course, can be defined with any certainty; much less can we form any accurate estimate of the obstacles which occur to the blood's motion; which must considerably affect such a calculation. We may however approach in some degree to the truth, by collecting and comparing the results of probable conjecture. If we calculate the blood contained in the body at thirty pounds, the number of pulsations in one minute at 75, and the quantity expelled from the left ventricle at each pulsation at $2\frac{1}{2}$ ounces, the whole quantity will pass through the heart about twenty-three times in the course of an hour; it will perform the circulation once in less than three minutes. The velocity with which this blood is propelled by the systole of the left ventricle may be collected from the violence with which it is ejected from a wounded artery; and the altitude to which it ascends. Blumenbach has seen it projected more than five feet from the carotid of an adult during the first contractions of the heart. Our countryman Hales calculated from his experiments, in which he measured the height of the blood's ascent in a glass tube, inserted into a large artery, that it would be thrown $7\frac{1}{2}$ feet from the human carotid: he estimates the surface of the ventricle at fifteen square inches; and thus finds that 1350 cubic inches, or about 51lbs. weight, press upon the left ventricle, and must be overcome by its systole. Many other calculations of the powers of the heart have been formed upon mathematical principles: but different persons have been led to such opposite results, that we are warranted from this circumstance in disregarding them altogether. Borelli makes the powers of the heart equal to 180,000lbs.; Keill to eight ounces. Senac observes, that if a weight of 50lbs. be attached to the foot, with the knee of that side placed on the opposite one; the weight will be elevated at each pulsation: this weight is placed at a considerable distance from the centre of motion; and, allowing for this circumstance, he estimates the moving power at 400lbs.

This power of the heart, so wonderful both in extent and duration, must be referred to the irritability of the organ; in which point of view it seems far to exceed all other muscular parts of the body. That the immediate cause of contraction in this viscus arises from the presence of blood in its cavities, is shewn by the celebrated experiment of Haller; in which the longer duration of action in the right or left cavities was varied by influencing the supply of blood.

In the action of those muscles, which depend on the will; a supply of nerves, and a distribution of blood to the moving fibres, seem to be essential conditions. It has been disputed whether or not these circumstances are necessary in the heart; and what share they may contribute to the heart's action. We may observe, in the first place, that the actions of the heart are completely involuntary; that no exertion of the will can produce the smallest effect in accelerating, retarding, or otherwise affecting the actions of this part. Yet, various arguments prove that the nerves exert an influence over this organ. Not to mention the peculiar arrangement of the cardiac nerves; the sympathy between the heart's action, and nearly every other function, even of the most different classes, suffices to demonstrate the connection. The vehement disturbance of the heart from the passions of the mind must be familiar to every person from his own experience: its action is also strongly influenced by various states and affections of the alimentary canal. That its irritability must be influenced by different states of the vascular system is rendered probable by the remarkable and copious apparatus of blood-vessels, which are distributed to it.

The action of the heart is intimately connected with the changes which the blood undergoes in its passage through the

the lungs. For when refpiration is obftructed, the heart's action ceafes; and it may be recalled by again introducing air into the lungs. Hence arifes the importance of inflating the lungs, in inftances of apparent death from drowning, &c. in order to excite the heart to action.

There is a mechanical power derived from the ftructure of the heart, which is faid to affift in the function of circulation. The blood being expelled by the fyftole of its cavities, they are in an empty and contracted ftate; a tendency to the formation of a vacuum now arifes, in confequence of which, the blood arriving by the veins immediately rufhes into the vacant fpace.

The other organs of circulation, befides the heart, are endowed with powers by which they contribute to the performance of this function. The arteries probably contribute effentially to the circulation, although the degree of their affiftance, and their mode of action, are not yet fatisfactorily explained. By their elaftic power, thefe veffels recover their original fize, after being diftended by the heart's action; and they muft of courfe urge on the blood proportionally. It is a fact moft familiarly known, that the arteries pulfate; and that they pulfate powerfully, fo that the courfe of the blood through the popliteal artery is fufficient, when we place one knee on the other, to elevate the whole leg and foot, even with the addition of a confiderable weight. Phyfiologifts have been long accuftomed to afcribe to thefe veffels a ftate of fyftole, or contraction, as well as a ftate of diaftole, or dilatation; which are confidered as alternating with the fimilar ftates of the heart; and the latter of which is referred to a mufcular power, or irritability, refiding in the arterial coats. It feems certain that the effect, which we call the pulfe, cannot be afcribed originally to any property of the veffel in which it occurs; but that its origin muft be derived from the contraction of the heart, and the confequent diftention of the arterial tube by the blood, which is then expelled from the left ventricle. We admit, therefore, a diaftole of the arteries, arifing from the lateral preffure of the blood, forcibly projected into thefe canals. That this pulfation is produced by the heart's action, is proved by aneurifms, and by the effect of ligatures on an arterial trunk; for thefe deftroy the pulfe in the arteries, beyond the part. We are not equally warranted in afcribing a true fyftole to the arteries; or a contraction of thefe veffels by mufcular power, to a fmaller area than that to which they are reduced by their elafticity. Nay, fome phyfiologifts have proceeded fo far, as to deny altogether the exiftence of irritability in the arteries; or at leaft to affirm, that the action of the heart alone fuffices to carry on the circulation. The following arguments feem to prove the exiftence of mufcular powers in the arteries, and their actual exertion in the living body. We have already fhewn that the caufes which would retard the blood's motion in dead tubes, do not feem to operate in the arteries of the body: this can only be explained, by fuppofing them to be overbalanced by fome powers refiding in thefe veffels. If we divide an artery in a living animal, the orifice clofes; if we divide it for fome extent, it contracts gradually, fo as to become nearly fhut (Hunter on the Blood, p. 114.). The arteries of an animal bled to death are contracted to a fmaller area than their elafticity would bring them to; they may at leaft be diftended confiderably, and will not by their elafticity recover their former contracted ftate (Ibid.). The functions of the arteries argue the poffeffion of living powers: by thefe the growth and formation of the various parts of the body is affected; they perform the different fecretions: thefe phenomena, as well as thofe of blufhing and palenefs, cannot be accounted for, if we confider the arteries merely as dead tubes. The great fupply of nerves which thefe veffels poffefs in many parts of the body, *viz.* the branches of the carotid, the arteries of the neck, and thofe of the cheft and abdomen, is a prefumptive proof to the fame effect. In fome rare inftances the heart has been wanting in fœtufes, otherwife well formed: we muft fuppofe that there was a circulation which muft, under thefe circumftances, have been carried on by the veffels only. It has been ftated, in oppofition to the irritable power of the arteries, and to their fyftole as aiding the circulation, that ftimuli which affect other mufcles caufe no figns of irritability in thefe tubes. That an artery, laid bare in the living fubject, cannot be feen to contract; that if divided, its diameter is not leffened in the fuppofed ftate of fyftole; that the blood flows in a continuous ftream, excepting as far as it is affected by the heart's action. (Kirkland on the prefent ftate of medical furgery, vol. 1. p. 306. et feq.) Hence Blumenbach ftates it as his opinion, that the arteries do not contract in the healthy ftate, or as long as the heart is adequate to the natural performance of its functions; but if thefe veffels are affected by preternatural ftimuli, or if the heart's action, from whatever caufe, become deficient, then the vital powers of the arteries will ferve as an auxiliary force for keeping up the circulation. Blumenbach Inftit. Phyfiol. fect. 7. § 130. Laftly, all obfervers agree in ftating that the blood flows with an uniform current through the fmaller ramifications; and it has been generally allowed, that this is the cafe in all arteries of lefs than one-fixth of a line in diameter. Now we fhould infer from reafoning *à priori*, as Mr. Hunter has actually affirmed, that the mufcular force of an artery would increafe in a direct ratio with the diminution of its fize, (On the Blood, p. 122,) for the auxiliary power muft be the more required, in proportion as we recede from the fource of motion. But if either thefe fmall arteries, or the larger ramifications which immediately precede them, contribute to the circulation by any actual contraction, the blood's motion could not appear regular and uninterrupted. Thefe, which appear to be the principal arguments on both fides of the queftion, are left to the confideration of the reader. Further proofs and illuftrations, derived from accurate obfervation in living animals, and from a comparative view of the organs of circulation in the different orders of animals, feem to be required, before a decided and fatisfactory opinion can be formed on the fubject.

Some phyfiologifts, being of opinion that the action of the heart could not reach to the fmalleft order of fanguiferous veffels, have afcribed the paffage of the blood in the minute arteries, and thence into the veins, to an ofcillatory motion of thefe parts, and have employed this explanation in the doctrine of inflammation. Microfcopical obfervation, however, detects nothing but an uniform progreffive motion in the fmall veffels.

There is little to be faid refpecting the powers which belong to the veins, fince thefe veffels obvioufly take a lefs active fhare in the circulation than the other parts of the fyftem. The return of the blood through the veins is only effected by the preffure from behind of the arterial blood, affifted by the valves, which prevent any retrograde motion.

Circulation of the Blood in the Fœtus.

The defcription which we have juft given, applies to the circulation as it is performed in the adult fubject; this function differs confiderably in the fœtal ftate; and the difference is caufed from fome variations in the ftructure of the heart, and adjacent veffels, which arife from the connection eftablifhed between the mother and the child, through the medium of the placenta, and from the want of refpiration. See Heart and Placenta.

The

The ſituation of the child in utero precludes the acceſs of atmoſpheric air to its lungs; theſe organs are conſequently ſmall and collapſed; and the leſſer circulation of the blood cannot be ſaid to take place in the fœtal ſtate. Although its circulation might be conſidered in this reſpect as more ſimple than that of the adult, this function becomes conſiderably complicated by the connection with the placenta. A portion only of the child's blood circulates through this part; and it is no doubt ſo altered or modified by this paſſage through the veſſels of the placenta, as to be rendered more fit for the growth and nouriſhment of the child. No ſuch alteration or modification has however been actually demonſtrated in the fœtal blood. Phyſiologiſts have diſcovered no difference in this fluid in the various veſſels of the fœtus. It is of the ſame dark colour in the arteries and veins. The interruption of the communication with the placenta, before reſpiration has commenced, is however ſuddenly fatal. Our ignorance of the functions of the placenta, and of the liver, which is of immenſe ſize in the fœtus; as well as of the changes which the fetal blood probably undergoes in the complicated ſyſtem of organs, which are connected with its circulation in this ſtate of exiſtence, leaves many parts of the ſubject in doubt and obſcurity.

The blood, which has paſſed through the placenta, is returned to the ſyſtem of the child by the umbilical vein; it is chiefly diſtributed through the liver, and is ſent in a ſmaller quantity by the ductus venoſus directly into the trunk of the inferior cava. This veſſel, paſſing in an oblique aſcent from the right towards the left ſide, ſends its blood into the left auricle through the foramen ovale; the Euſtachian valve preventing it from paſſing towards the right ventricle. The valve of the foramen ovale guards againſt the poſſibility of its return to the right ſide of the heart. The ſuperior vena cava pours its blood into the right auricle and ventricle, as it paſſes obliquely into the former cavity, in a direction from before backwards, and from the right towards the left ſide. The thick ſuperior margin of the foramen ovale concurs with this direction in preventing any paſſage towards the left auricle. The continuation of the trunk of the pulmonary artery, under the name of ductus arterioſus, into the aorta, conveys this blood into the poſterior part of the arch of the latter veſſel, and it is hence tranſmitted in great meaſure by the umbilical arteries to the placenta. It appears, therefore, that the blood of the inferior vena cava, including that which has recently circulated through the placenta, is ſent entirely to the head and upper extremities, through the branches of the aortal arch; while that portion of this fluid, which returns to the heart through the ſuperior cava, is ſent to the deſcending portion of the aorta, and therefore in great part to the placenta. Hence Sabatier has obſerved, that the courſe of the blood in the fœtus may be compared to the figure 8, the point of decuſſation being in the heart. This fluid is tranſmitted through the umbilical vein, the inferior cava, and the foramen ovale, into the left auricle and ventricle; from which the three large branches of the arch of the aorta conduct it to the head and upper extremities. The ſuperior cava returns it to the heart; it goes through the right auricle and ventricle, the ductus arterioſus, and the aorta, to the umbilical arteries, which return it to the placenta. By this arrangement, the blood, which has gone through the placenta, is not returned to that part, until it has circulated through the whole ſyſtem of the child; whereas, by the opinion, which ſuppoſes a mixture of the blood of the two venæ cavæ in the right auricle, it follows, that a portion of the placental blood would return to that part, without circulating in the ſyſtem of the child; and the blood, which had already gone through the proper veſſels of the fœtus, would recommence its courſe in theſe ſame veſſels, without receiving the ſalutary influence, which is probably exerted on it by the placenta. Sabatier derives from this expoſition of the courſe of the blood, an explanation of the relatively diminutive ſize of the lower parts of the body, when compared with the head and upper extremities of the fœtus. The former parts, ſays he, are ſupplied with a leſs pure blood. We cannot, however, admit this phyſiology. The phenomenon in queſtion ariſes out of the future ſtate of the human embryo, and muſt be conſidered in connection with the long ſtate of helpleſs infancy, to which the individuals of the human ſpecies are excluſively devoted in the early periods of their exiſtence. In quadrupeds, which are obliged to go alone almoſt from the moment of their birth, theſe proportions are not found; although their veſſels are diſtributed in the ſame manner as in the human fœtus. The embryos of the quadrumana, and of the ſquirrel, the foal, &c. are examples of this fact.

The differences in the ſtructure of the heart and circulating veſſels in the fœtus, are ſuch that they are readily and eaſily changed after birth, ſo as to become accommodated to the alterations which take place in the new mode of exiſtence. Two ſtriking and eſſential changes in the animal economy are co-eval with birth, *viz.* the obſtruction of the placental circulation, and the commencement of reſpiration. The former of theſe diminiſhes the quantity of blood conveyed to the right auricle by the inferior cava; the latter cauſes a developement of the ſtructure of the lungs, and a conſiderable enlargement of the pulmonary veſſels; ſo that the left auricle receives more and more blood from the pulmonary veins. Hence the quantity of blood contained in the two auricles becomes equal; and the foramen ovale is cloſed by its valve growing to the margin of the apertures. The ductus arterioſus now contracts; ſo that the whole blood of the pulmonary artery muſt circulate through the lungs in its courſe from the right to the left ſide of the heart. The Euſtachian valve gradually diminiſhes as its function has ceaſed; the umbilical arteries and vein cloſe. Thus the heart and veſſels become adapted to the double circulation, which belongs to the perfect animal. Theſe changes take place gradually, and not abruptly; it is many months, nay even one or two years, before the foramen ovale is cloſed. The ductus arterioſus contracts much more rapidly; indeed this veſſel, as well as the umbilical arteries and vein, are impervious within a very ſhort period after birth.

We refer the reader, on the ſubjects of this article, to the 3d, 4th, and 6th books of Haller's "Elementa Phyſiologiæ." Senac, "Traité de la Structure du Cœur, de ſon Action, et de ſes Maladies." Hales's "Statical Eſſays," vol. ii. Blumenbach "Inſtitutiones Phyſiologiæ," ſect. 7. Spallanzani's "Experiments on the Circulation of the Blood." Sabatier "Sur les Organes de la Circulation du Sang du Fœtus," in his "Traité Complet d'Anatomie," tom. iii.

Circulation, *diſcovery of.* The vaſt importance of this diſcovery to the whole ſcience of phyſiology; the influence which it neceſſarily exerted on the doctrines of pathology; and the general revolution which aroſe from this ſource throughout the whole circle of medical knowledge, will juſtify us in giving a ſlight hiſtorical ſketch of the ſubject, and in pointing out the opinions held by thoſe anatomiſts and phyſiologiſts who preceded our immortal countryman Harvey. To him, indeed, the glory of this greateſt of all phyſiological diſcoveries has been aſſigned by the almoſt unanimous concurrence of his ſucceſſors. Some, however, have endeavoured to deprive him of his well-earned fame, by aſcribing a knowledge of the circulation to various preceding writers. Mr. Dutens, in the ſecond volume of his "Recherches sur l'Origine des Decouvertes attribueés aux Modernes," has brought forwards paſſages from Hippocrates, Plato, Ariſtotle, Julius Pollux, Apuleius, and others, in order to prove that they knew the courſe of the blood. After the poſitive dogmatical aſſertions with which the author ſets out, we are ſurpriſed by the weakneſs and inadequacy of his proofs, and can only account for the inconſiſtency by ſuppoſing him to have been utterly ignorant of the ſubject. He quotes a few iſolated paſſages which cannot, by the moſt favourable interpretation, be conſtrued into the ſemblance of a proof, that the writers in queſtion knew the circulation of the blood. Thus he adduces the following paſſage from Hippocrates: "Venæ per corpus diffuſæ, ſpiritum, et fluxum, ac motum exhibent, ab unâ multæ germinantes; atque hæc una unde oriatur, et ubi deſinat, non ſcio: circulo enim facto, principium non invenitur." Another equally unſatisfactory follows from Plato: "Cor vero venarum originem, fontemque ſanguinis per omne corpus impetu quodam *manantis*," the Greek word is περιφερομενα. Theſe are really the ſtrongeſt quotations which Mr. Dutens has furniſhed on the ſubject, ſo that nothing more would be required in order to diſprove his opinion, than to examine the very paſſages which he adduces in ſupport of it.

Let us further remark, on the ſame point, that this ſpecies of argument, derived from the conſideration of ſingle words and paſſages, is by no means a ſatisfactory one. A ſentence or term employed accidentally and undeſignedly, may ſuggeſt to the mind of a perſon acquainted with all the details of a ſubject, various notions that were not in the contemplation of the writer, and may very probably have been unknown to him; while they would be paſſed over without attention by a perſon not poſſeſſing this previous knowledge. The only fair and unexceptionable method of determining whether any individual was acquainted with a particular fact, is to conſider all that he has ſaid on the ſubject, and to draw our inferences from the reſult of this general examination. Such an inquiry will prove moſt clearly, that a knowledge of the circulation, ſuch as we poſſeſs at preſent, can be aſcribed to no one before Harvey; although a part of the ſubject, viz. the paſſage of the blood through the lungs, had been deſcribed by ſeveral perſons before the time of that illuſtrious character.

That the blood moves, has been univerſally known and admitted, ſince the ſcience of medicine has aſſumed a diſtinct form: how much of its courſe, and of the laws that regulate its motion, has been aſcertained at any given period, is another queſtion. The circulation is ſo generally known in the preſent day, and the proofs on which it reſts are ſo obvious and familiar to every tyro in the profeſſion, that we feel ſurpriſed how they ſhould ſo long have eſcaped the obſervation of the numerous ingenious and learned characters, whoſe names adorn the annals of anatomy. We muſt remember that the courſe of the blood, taken altogether, forms a ſubject of conſiderable intricacy; that the purſuit of anatomy was attended in the early periods of the ſcience with conſiderable difficulty and danger; and that the unlimited ſway which the authority of Galen held over the minds of men for ſome centuries, precluded all attempts at further inveſtigation. We may alſo account for the ignorance of the ancients on this ſubject, by remembering the juſt diſtinction which Haller has drawn, between the kind of information which may be reaſonably expected from them and that which cannot be looked for in this ſource, "Faciles ab antiquitate ſperamus, quæcunque ex ingenio ſolo naſci poſſunt; id enim, ſub felici cælo hominibus vitæ negotiis minus implicitis, ſummum fuit. Quæ verò multiplici, neque a caſu ſperabili, ſed imperato ad ſuos fines experimento nituntur, ea ab eâ ætate non ſperes." Bibl. Anat. tom. i. p. 9.

Hippocrates ſtates that the blood meets with obſtacles in its courſe, which retard or entirely arreſt its progreſs; that it goes from the internal parts towards the ſurface: and *vice-verſâ*, that the blood muſt flow forwards from the heart, ſince the valves hinder its return, and that the arteries are diſtended, when their blood is ſtopped. In ſpeaking of the blood's motion he compares it to the courſe of rivers, to the ebbing and flowing of the ſea, and even to the revolutions of the planets. He aſſigns the origin of the arteries to the heart, and that of the veins to the liver, and ſuppoſes that there are two oppoſite motions in the temporal arteries, by which their pulſations are produced. He ſpeaks of four fluids in the body, the blood, water, mucus, and bile, which come from the heart, head, ſpleen, and liver; all thoſe parts are, however, ſupplied from one principal ſource, the ſtomach.

Can we diſcover any traces of a knowledge of the circulation in this confuſion of ideas? and may we not be juſtly ſurpriſed, to find that enlightened men ſhould be ſo led away by their prejudices, as to allow to Hippocrates the knowledge of a diſcovery, which no one had perceived in his writings for nearly three thouſand years? The obſervations of the founder of medicine had led aſtray all who followed him to the time of Harvey; but when the reſearches of that great man had unfolded the myſtery of the circulation, his enemies dared to affirm, that the writings of Hippocrates had furniſhed the lights which guided him in the path of diſcovery.

The philoſophers who joined the ſtudy of medicine to that of the other ſciences, ſeem to have been equally ignorant of the laws which regulate the blood's motion. A paſſage has been already quoted from Plato on this ſubject; but it would be a moſt remarkable inſtance of liberality to allow him, on the credit of the vague and indefinite expreſſion, which he there employs, the honour of an admirable diſcovery, which he would have explained more clearly if he had known, or even ſuſpected it. In the ſequel to this paſſage, he employs various allegories, in which the heart is a ſentinel or officer to receive the orders of the ſoul, and convey them to all parts. Ariſtotle expreſsly ſtates that the blood never returns to the heart.

The Alexandrian anatomiſts maintained that the arteries held no blood, but were filled with air; from which circumſtance they gave them the name, which they have conſtantly retained, from αηρ, air, and τηρεω, to hold. To explain the occurrence of blood in theſe veſſels after death, they ſuppoſed the exiſtence of ſubtle communications with the veins.

The genius of Galen diſdained to follow blindly the ſteps of his predeceſſors; and he endeavoured at leaſt to diſcover the truth by experiments, and obſervations on the ſtructure of the body. By theſe means he aſcertained ſome facts, although he could not ſucceed in piercing the veil which concealed the ſecret of the circulation. He ſeems to have recognized the uſe of the valves at the two orifices of the ventricles. He proved, by tying an artery with two ligatures, that theſe veſſels contain blood during life; and ſtates that they are filled by the contraction of the heart, in conſequence of which they pulſate. Theſe circumſtances ſeem to indicate a conſiderable advancement in the knowledge of the circulation; but we muſt mention, in the ſame ſpirit of impartiality, the contradictions and uncertainty which prevail in the works of Galen on this ſubject, and the limits which his labours could not exceed. He ſtill referred, with Hippocrates, the origin of the veins to the liver, and ſuppoſed a paſ-

ſage

fage of the blood through the feptum of the ventricles, while a fmall portion entered the pulmonary artery to nourifh the lungs: he imagined laftly, that it might pafs reciprocally between the pulmonary artery and veins.

There could be little reafon to expect, that in the troubled and barbarous times, which followed the age in which Galen flourifhed, the fecret of the circulation fhould be difcovered; ftill lefs that it fhould be explained to phyficians by men, whofe purfuits were foreign to the fcience of medicine. Yet it has been boldly afferted that Nemefius, bifhop of Emefa, knew the courfe of the blood, as it has been afcertained by the fubfequent labours of Harvey. The editor of the Oxford edition of his works, has imbibed the true fpirit of a commentator; who difcovers in the writings of the ancients, meanings which never were in the contemplation of the authors; and abufes the moderns as plagiarifts, for decorating themfelves with the difcoveries of antiquity.

But on what grounds does Nemefius claim the honour of a difcovery, denied to fo many great geniufes? Becaufe, according to Freind, the bifhop ftates, that the blood paffes from the arteries into the veins during fleep. This reftriction immediately overturns the claim; which would indeed be deftroyed by the kind of motion that he fuppofes to take place, *viz.* a reciprocal alternation of undulations, like that of the Euripus. In another paffage cited by Dutens, he fpeaks of the arteries in their dilatation attracting the blood from the veins; which fufficiently proves that he knew nothing of the matter; and exemplifies ftill further the abfurdity of a perfon's attempting to dogmatize as Dutens has done, on fubjects of which, as being foreign to his profeffion, and difficult of inveftigation, he cannot reafonably be expected to be a competent judge. "Thus," to ufe the words of Senac, "a theologian writes on the nature of man; a fubject which does not very properly belong to fuch a writer: on no other teftimony, than fome vague and ridiculous expreffions, he gains the credit of knowing the circulation, of which the greateft phyficians and anatomifts had been hitherto completely ignorant. Thus it is, that interpreters and commentators are mifled by a blind zeal for antiquity, and difcover hidden meanings in the moft fimple expreffions. How would their boldnefs and affurance have been augmented, if Nemefius had expreffed himfelf as clearly, as an ancient fcholiaft of Euripides has done, where he fays, "that the blood flows through the veins, and that thefe veffels receive it from the arteries." Should we, however, on this infulated and cafual expreffion, be juftified in beftowing on a weigher of words, and meafurer of phrafes, the honour of a difcovery, which had eluded the refearches of the greateft philofophers?

The ftate of darknefs and ignorance, in which the human mind languifhed during the fucceeding ages, does not allow us to expect that any writer of that period can difpute with Harvey the honour of the great difcovery. About the fixteenth century the curiofity of mankind was again excited to the inveftigation of this interefting fubject. Reafon, which had hitherto fubmitted to the yoke of authority, began to affert her rights; and feveral phyficians were bold enough to examine fubjects, which Hippocrates and Galen had not been able to develope.

The firft ray of light was thrown on the circulation, by a man, whofe name cannot be mentioned without exciting feelings of compaffion for his unmerited and barbarous treatment, and of indignation at the unrelenting bigotry of his cruel perfecutor, and implacable judge. Gifted with an ardent and penetrating genius, Servetus made a rapid progrefs, at a very early age, in the fciences of natural philofophy and divinity. By applying the rigorous, and exact kind of proof required in fubjects of the former kind, to the latter fcience, he refufed to affent to propofitions, which he could not comprehend; and openly declared his difbelief of the facred myftery of the Trinity. This compelled him to leave Spain his native country; from which he paffed into France, and ftudied medicine at Paris, under Winter d'Andernach, who was profeffor in the college lately founded by Francis I. He vifited different parts of France and Germany, and after various perfecutions on account of his religious opinions, fettled in Dauphiny. But the reformer of Geneva, either being too narrow-minded to grant to a rival, that freedom of thought, and liberty of confcience, which he had fo fuccefsfully exerted in his own perfon; or fearing that his fchemes of aggrandizement would be interrupted by the fuperior talents of Servetus; had him feized and condemned to the flames. Thus, fays Portal, one heretic deftroyed another; but the difference was, that an ambitious and defigning knave pronounced the condemnation, and one of the fineft and moft enlightened geniufes of Europe was the lamented victim of this iniquitous fentence.

The paffage, which proves Servetus to have been acquainted with the pulmonary circulation, occurs in his work de Reftitutione Chriftianifmi; which having been carefully deftroyed on account of the herefy which it contains, is now extremely fcarce; fo that two or three copies only are fuppofed to exift, and the duke de la Valiere gave the fum of 132*l.* for one. Blumenbach Introd. in Medic. Literar. p. 125.

He ftates that the vital fpirit is compofed of the moft fubtile parts of the blood, and of the air, which infinuates itfelf into the lungs; and that the fource of this blood is in the right ventricle. "But the communication, that is to fay, the paffage of the blood from the right to the left ventricle, does not take place acrofs the middle feptum, as perfons have generally imagined; it depends on a more fingular ftructure. In the long windings of the lung, this fubtile blood is agitated, and prepared by the action of the vifcus, and gains a yellow colour. From the *vena arteriofa*, (pulmonary artery), it paffes into the *arteriæ venofæ*, (pulmonary veins), where it becomes mingled with the air that has entered the lungs, and lofes its fuliginous excrements. Laftly it enters the left ventricle, which attracts it in its diaftole. Such is the preparation of the blood, from which the vital fpirit is formed; this preparation, and this paffage from the arterial vein into the venous artery, are evidently proved by the fize of the veffels; which would not be fo large, nor poffefs fo many branches; nor carry to the lung fo great a volume of blood, if it were deftined to the nourifhment only of the vifcus." He adds that the vital fpirit is fent from the left ventricle into all the arteries of the body.

This reprefentation proves inconteftably that Servetus knew the minor circulation. He laid the foundation of a building, which had baffled all the efforts of the great geniufes of antiquity. In order to perfect this defign it was only neceffary to extend the ideas of the firft architect. He indicated the route, through which the blood paffes from the right to the left ventricle; it remained to be proved that all the blood takes this paffage, and that it returns again to the heart from the arteries through the veins.

The obfcure fketch of the circulation, which was furnifhed by Servetus, appears in a more finifhed and luminous form in the works of Realdus Columbus. He defcribes the entrance of the blood into the heart from the vena cava, and its fubfequent paffage through the lungs into the left ventricle

tricle and aorta. He advanced a ſtep farther than Servetus; for he ſtates that the whole blood paſſes through the lungs, and not the vital ſpirit only. But he falls into the ſame error with preceding anatomiſts on the ſubject of the liver; ſuppoſing that gland to be the ſource of the blood which nouriſhes the ſtomach, ſpleen, &c.

Arantius and Cæſalpinus deſcribed more perfectly and clearly than Columbus, the paſſage of the blood through the lungs; which they confirmed by ſeveral arguments drawn from the ſtructure of the parts, and particularly from the poſition and mechaniſm of the valves. The latter indeed approached very nearly to the grand deſideratum, the paſſage of the blood from the arteries through the veins to the heart. He obſerves that a vein ſwells below the ligature; but he did not follow this up to prove the circulation. He ſays that the blood returns to the heart through the veins during ſleep; but he ſuppoſed it to move backwards and forwards in the ſame veſſels, like the Euripus. He was miſled alſo in the labyrinth of the liver, where ſo many phyſiologiſts have loſt themſelves. The arrangement of the arteries and veins in this organ preſents ſuch an intricate combination that we need not wonder at its proving, for ſo long a time, a ſource of miſtake and illuſion.

Paul Sarpi, the learned hiſtorian of the council of Trent, is one of thoſe to whom the circulation is ſaid to have been known; but the want of all arguments that bear the leaſt conviction on the ſubject, will juſtify us in declining any particular conſideration of his claim, as well as thoſe of Fabri, a Jeſuit, of Helvicus Dietericus and others.

Notwithſtanding the labours and writings of the anatomiſts, whoſe opinions we have thus curſorily examined, the minds of men were ſtill enſlaved by thoſe errors, which, having prevailed for ſo many centuries, had acquired the ſanction which time and authority beſtow on any opinions, however abſurd. The moſt enlightened phyſicians were ſatisfied with the labours of their predeceſſors: and Harvey alone had ſufficient courage and information to canvaſs theſe inveterate prejudices, which length of time had conſecrated as infallible truths. He obſerved and deſcribed the true courſe of the blood with a wonderful ſagacity and clearneſs. None of the arguments, which prove the circulation, eſcaped the reſearches of this acute obſerver; ſo that a modern phyſiologiſt, in recounting the proofs of this phyſiological fact, could add little, if any thing, to what is accumulated in the original work of Harvey. He was not contented with demonſtrating the circulation in ſome parts only; but followed up the ſubject in all the viſcera of the body. He traced the courſe of the blood through the liver, where every preceding anatomiſt had diſcovered nothing but perplexity and confuſion. The work of Harvey is, in ſhort, one of thoſe rare and precious productions which embrace a ſubject in its whole extent, and preſent it to the mind in ſo perfect and finiſhed a form, as ſcarcely to admit a ſingle addition or improvement.

The merits of our countryman, whoſe fame can never periſh, while medical ſcience continues to be cultivated, will be exalted to a ſtill higher pitch, when we conſider the ſtate of medical knowledge in England at that time. While anatomical ſchools had been long eſtabliſhed in Italy, France, and Germany, and ſeveral teachers had rendered their names illuſtrious by the ſucceſsful purſuit of the ſcience, anatomy was ſtill unknown in England, where diſſection had hitherto hardly begun. Yet, at this inauſpicious period, did Harvey make the diſcovery, which may be conſidered as a ſecond and more perfect foundation of the ſcience of medicine; and which amply juſtifies Haller in ranking him as ſecond to Hippocrates only.

Harvey ſtudied anatomy at Padua under Hieronymus Fabricius; who had inveſtigated more minutely, and deſcribed more accurately the valves of the veins firſt diſcovered by Cannanus. Returning to his own country, he commenced a ſeries of experiments on living animals; and taught the circulation in his lectures about the year 1616. But he did not publicly promulgate his grand diſcovery till 1628, when his "Exercitatio anatomica de Motu Cordis et Sanguinis in Animalibus" appeared at Frankfort: and this is the only edition, which bears the ſtamp of Harvey's own authority. This treatiſe, which Haller has moſt appropriately ſtyled "aureum opuſculum," is conſtructed entirely upon the reſult of experiment, and contains an excellent arrangement of the ſubject. The author was now created phyſician to king Charles I. and demonſtrated the circulation before him in a living animal.

The publication of this grand diſcovery rouſed the attention of all Europe. The old profeſſors, accuſtomed to pay a blind and implicit deference to the authority of Galen, which was now utterly ſubverted, and, aſhamed of confeſſing that their whole life had been ſpent in teaching the groſſeſt errors, took up their pens in oppoſition to the author of theſe innovations. One party aſſerted that the diſcovery was not a new one: that it had been known to ſeveral perſons, and, indeed, to all antiquity. Such were the aſſertions of Nardi, Vander Linden, Hartmann, Almeloveen, Barra, Drelincourt, Patin, Falconet, Heiſter, Regnault, &c. A ſufficient refutation of theſe ſtatements will be found in the hiſtorical ſketch, which we have already exhibited. Other adverſaries of Harvey proceeded in a more rational manner; and attempted to diſprove his ſtatements by experiment and reaſoning. Primeroſe led the way in this attack, and he was followed by Emilius Pariſanus, Joh. Riolan, Caſp. Hoffmann, and others. If men of ſuch acknowledged erudition as Riolan and Hoffmann were ſo utterly unacquainted with the circulation, as to deny it altogether, may we not ſafely conclude that the ſubject is not deſcribed in any of the writers, who preceded Harvey? Out of all his numerous opponents, this illuſtrious man anſwered Riolan only; in his "Secunda et tertia exercitatio de circulatione ſanguinis." The reply was rather extorted by the rank, fame, and learning of Riolan, than by the ſtrength of his arguments. If we ſeek to define exactly the preciſe ſhare of merit which Harvey may claim in the diſcovery of the circulation, it will be neceſſary to hold a middle courſe between the groſs and palpable abſurdity of thoſe who diſcover a knowledge of the circulation in the writings of Solomon, Hippocrates, Plato, Ariſtotle, &c., and the too great partiality of ſuch as would deny all knowledge of the ſubject to every anatomiſt who preceded Harvey. It ſeldom happens, that ſo extenſive and intricate a ſubject as that which we are now conſidering, is ſurveyed and brought to light in all its branches by the labour of an individual; nor has it happened in the preſent inſtance. For Servetus, Columbus, Arantius, and Cæſalpinus, were acquainted with the courſe of the blood through the lungs; and the latter writer has even an obſcure hint towards the greater circulation. But no one attempted to prove the latter point by arguments and experiment before the time of Harvey: the expreſſions of Cæſalpinus, which are by no means clear or ſatisfactory, had been before the public for half a century without exciting the leaſt inveſtigation, and without ſuggeſting to Fabricius the true office of the valves in the veins. The entire merit of the greater circulation may, therefore, be aſcribed to our illuſtrious countryman; and if we compare the luminous method, and irrefragable proofs which are found

found in his expofition of the other part of the fubject, with the partial and confufed ftatements of preceding authors, his merit will here be only fecond in degree to that of actual difcovery.

The doctrine of the circulation met with fome fupporters on its firft promulgation. Walæus of Leyden exerted himfelf ftrenuoufly on this fide, and defended the propofitions of Harvey in two excellent letters addreffed to Bartholin. Des Cartes alfo, whofe authority at that time carried vaft weight with it, took a decided part in the controverfy in favour of Harvey, from its commencement. The doctrine was pretty generally admitted throughout Europe before the deceafe of its propofer.

The nature of the communication between the arteries and veins was left undetermined by Harvey, who decided no point which he could not make the fubject of experiment. The art of injecting the veffels of the dead body, which has been difcovered and carried to great perfection fince his time, has fhewn a continuation of canal joining the two fyftems of blood-veffels: and the employment of the microfcope has completed the proof, by demonftrating the circulation in the tranfparent parts of frogs, &c. during life. The transfufion of the blood of one animal into the veffels of another, which has been performed with fuccefs in many inftances, has added another ftrong proof to the demonftration of the circulation. See the "Hiftoire de l'Anatomie, et de la Chirurgie" of Portal, and the "Bibliotheca Anatomica" of Haller, in the articles concerning the writers, whofe names are mentioned in this account; "Elementa Phyfiologiæ," tom. i. fect. 3. Senac "Traité du Cœur," livre 3. Dutens "Recherches fur les Decouvertes attribuées aux Modernes."

Circulation *of the Sap*, in *Vegetable Phyfiology*, is a fubject which has been long involved in the utmoft obfcurity. After the difcovery of the circulation of the blood in animals, feveral diftinguifhed philofophers, who beftowed attention upon the anatomy and phyfiology of plants, expected to difcover fomething equivalent in their conftitution. The flighteft obfervation was fufficient to determine that the juices of the earth were abforbed by the roots of plants, and pervading their fubftance, fupplied them with nourifhment, thus contributing effentially to their health and increafe. This regular propulfion of fluids through the vegetable body is evinced by taking an entire plant with its root, or even a branch cut from its parent ftem, and after it has begun to droop, placing its lower extremity in water. By the abforption of the water through its veffels, the plant or branch will foon revive, and continue in vigour for a longer or fhorter period, according as the circumftances in which it is placed may be more or lefs favourable. It was alfo very foon difcovered that an extraordinary motion of the fap took place at a certain time of the year. If a vine, for inftance, be wounded in the fpring, juft before its leaf-buds open, it *bleeds*, as the gardeners exprefs it, that is, the fap runs out very abundantly, infomuch that if the wound be not ftopped, the experiment is fatal to the branch on which it is made. The fame thing was obferved in the birch, whofe fap fo procured is, in fome countries, manufactured into wine, as that of the American fugar-maple, *acer faccharinum*, is made to yield fugar. This bleeding does not take place if the vine be cut after the leaves begin to expand; but in autumn, after a flight froft, not during the froft, the fap runs in a fimilar manner from a wound, though in a far lefs degree. This is called technically the *flowing of the fap*. An ordinary branch of a vine will yield about a pint in 24 hours. The liquor thus obtained is clear and colourlefs, with little fmell or tafte, and feems fcarcely different from common water, yet it foon undergoes chemical changes, which fhew it to be fomething more. The peculiar fecretions of the vine, which are very acid, alfo come along with it, and ftill more thofe of the birch and fugar-maple; fo that the perfectly pure fap, or nutritious fluid of any plant, is fcarcely to be obtained unmixed with adventitious matter.

When this flowing of the fap began to be ftudied by phyfiologifts, their fanguine hopes of detecting the vegetable circulation by its means were not at all anfwered. In vain were ligatures tried to difcover its courfe, as had been practifed with fo much fuccefs on the veins and arteries of animals. Nothing like a fwelling from a ftoppage of the fap in its paffage, by ligatures, and confequent accumulation in the veffels, has ever been perceived in vegetables. It was obferved to flow equally from both fides of a tranfverfe wound, and in as great quantity from the portion of the ftem or branch above the wound as below it, at leaft till the upper portion, not being fupplied from the root, was exhaufted. It was alfo feen to proceed always from the wood, not from the bark. Some authors having thought they obferved the fap to flow more abundantly from the lower fide of an incifion during the heat of the day, and from the upper in the cool of the evening, have afferted that it mounts during the former period, and defcends at the latter. But the moft furprizing circumftancee of all was, that after the leaves were expanded, when it was known that a great perfpiration was going on through thofe organs, and that there confequently muft be as great and conftant a propulfion of the fap at leaft as took place before, no fuch violent movement in that fluid could be perceived; for during the greater part of the year only a flight effufion of fap happens from a wound. Dr. Smith, taking all thefe phenomena into confideration, has fuggefted that probably this great motion in the fap, which has been univerfally believed to exift in trees for a fhort period before their buds open, is altogether imaginary. He is perfuaded the fap is at that period, as well as through the winter, (in deciduous trees at leaft,) quiefcent, and that it has in fpring merely an extraordinary propenfity to run, caufed by the reviving warmth of that feafon, and the accumulated irritability of the vegetable conftitution during winter. For this reafon the fap flows in fome degree in a warm autumnal day after a froft, the cold having increafed the fenfibility of the plant to the warmth which follows, and thus what happens in winter and fpring is acted for a fhort period on a fmall fcale. This flowing of the fap, or fpeaking more correctly, this facility of the fap to run, is therefore the firft ftep towards the revival of vegetation in the fpring, and its exciting caufe is heat, doubtlefs by ftimulating the vital principle, and not by any mechanical action. The effect of heat in this refpect is in proportion to the degree of cold to which the plant has previoufly been expofed. In forced plants the irritability is exhaufted, according to the remark of Mr. Knight in the "Philofophical Tranfactions for 1801," which is ftrikingly to our prefent purpofe.

"It is well known," fays that gentleman, p. 342, "that the degree of heat required to put the fap into motion, in the vine, is not definite, but depends on that to which the plant has been previoufly accuftomed. Thus, a vine which has grown all the fummer in the heat of a ftove, will not be made to vegetate during the winter by the heat of that ftove; but, if another plant of the fame variety, which has grown in the open air, be at any time introduced, after it has dropped its leaves in the autumn, it will inftantly vegetate. This effect appears to me to arife from the latter plant's poffeffing a degree of irritability, which has been exhaufted exhausted in the former by the heat of the stove, but which it will acquire again during the winter, or by being drawn out and exposed for a short time to the autumnal frost.

For the same reason, all vegetation goes on better in the increasing heat of spring, than in the decreasing heat of autumn, and some plants, even of the most hardy kind, as radishes, which grow so freely at the former season, can by no art be made to vegetate at all in the decline of the year. An attention to this law of nature will enable us to procure flowers from many plants that do not readily blossom under ordinary management. The Cape jasmine, *Gardenia florida*, is best kept in a common greenhouse, secured from frost, till about April, when if exposed to the strongest heat of a bark bed it is made to flower in the greatest luxuriance.

The propulsion of the sap, in one direction at least, from the root upwards, being established, the next subject of inquiry is the system of vessels in which it runs. Malpighi and Grew, the leaders in this branch of philosophy, and all their followers, even the intelligent Du Hamel among others, were convinced of the existence of three kinds of longitudinal vessels in the vegetable body, sap vessels, air vessels, and vessels denominated *vasa propria*, containing secreted fluids. The last are obvious to the most careless observer, filled with the resin of the fir, the milk of the fig, celandine, &c. Air-vessels are found in most parts of a plant, of a roundish or oval form, intermixed with the *parenchyma* or pulp. So far is unquestionable; but the above ingenious observers thought they had also discovered longitudinal air-vessels. When a young branch of elder, the stem of a lily, and many other stems, branches, or leaf stalks, are partly cut through, and their two portions gently drawn asunder, a set of white spiral threads, of considerable strength, are unrolled in the substance of the young wood, not in the bark. Each of these threads forms the spiral coat of a vessel, the thread itself not being, as some persons have supposed, pervious. Such vessels are of sufficient diameter to be easily visible under an ordinary microscope, and when investigated with high magnifying powers, their structure is readily seen. They are always found nearly, if not quite, empty of moisture, and filled with air, and were therefore, by a similar mistake to what was formerly made concerning animal arteries, determined to be air-vessels, though no communication could be traced between them and the above-mentioned round or oval air-cells. The sap-vessels only remained to be ascertained. These, it was thought, could exist only in the woody fibres, which make so considerable a part of the bulk of a tree or shrub, and are abundant even in herbaceous plants. But philosophers sought in vain for any cavity in those fibres. They are divisible without end, nor can any perforation be detected. Still it was argued that as the *vasa propria* were always found full of secreted fluids, different in different plants, but all quite distinct from that universal lymph or sap, which is nearly uniform in all; and as the spiral-coated vessels were always full of air only; the sap could have no other course but along the woody fibres. It was even presumed that although these fibres were imperforate, the sap might ascend along them by capillary attraction, as through a spongy or cottony substance. This was Tournefort's opinion, and others have adopted it. Grew imagined that the nutritious fluids were absorbed by plants in a highly rarified form, and in that state pervaded their substance with the more readiness and force. Du Hamel guessed that the passage of air out of the air-vessels parallel to the woody fibres, causing the former to contract, must produce a power of suction in the latter, and so promote the conveyance of the sap, as well as its absorption from the earth. De la Hire went so far as to suppose, not only vessels, whose cavities he could not discover, in the woody fibres, but valves in those vessels, some having them placed so as to allow the sap to ascend, others in a contrary position. This imaginary structure, combined with fine theories of rarefaction and condensation, explained every thing that was wanted. "But unhappily," says the more faithful and more philosophical Du Hamel, "these valves, so commodious for all the above explanations, are a mere supposition. I have sought them in some plants of the reed kind, and have ardently wished to find them. I shall however relate plainly what I have been able to discover. After having succeeded in introducing coloured liquors in the longitudinal vessels of the plants in question, I thought I perceived in the centre of each vessel a firm longitudinal thread pervading its cavity throughout, which was rough, or clothed with a very fine pubescence. Such a structure is very similar to what M. Mariotte has discovered in the *vasa propria* of plants. Those who are so inclined may, if they please, suppose that this downy substance, being bent one way or the other, may perform the functions of valves, but after all, the whole will be but a supposition, to which some degree of probability only can be granted."

We have given the above passage from Du Hamel to shew, that nothing was really known in his time, concerning the true sap-vessels of plants.

Nor are the *reducent* vessels, confidently described by some recent writers as lodged near the pith, and which are supposed to return the sap towards the root, with more certainty to be demonstrated, at least as far as their functions are concerned, than the valves of De la Hire, whatever may be the case with the *adducent* vessels of the same authors, whose existence we are not disposed to deny.

But it is time to quit the regions of hypothesis, and to recur to facts and practical observations.

Dr. Darwin and Mr. Knight have shewn by clear experiments that the real sap-vessels are what had hitherto been considered as air-vessels, and which longitudinally pervade the *alburnum* or layer of new unhardened wood. Some of them have a spiral coat, others not, and these last probably are the adducent vessels of the authors above alluded to, who retain the old opinion that the others are air-vessels.

Young twigs of horse-chesnut, apple-tree, fig-tree, &c. whose lower ends are immersed in water stained with madder, log-wood, or the skins of very black grapes, imbibe such coloured fluids by their spiral-coated tubes. We have even found common ink to be absorbed by the *Hydrangea hortensis*, a shrub whose vascular system is large and easily discernible. But the fig perhaps is preferable to most other things for such experiments, as its white secreted juices, lodged in their appropriate vessels, are so strikingly contrasted with any coloured liquor which their sap-vessels may take up, and thus the course of the latter can be the more readily traced. Dr. Darwin pursued his observations to no great extent, but Mr. Knight, whose experiments are recorded in the "Philosophical Transactions for 1801," has traced the coloured fluids, not only along the main tubes of the branch, but has discovered how they are conveyed, by an appropriate set of vessels in every case, along the leaf-stalks into the substance of the leaves. The same most acute and ingenious philosopher has moreover discovered a set of returning vessels, commencing in the leaf, and conveying fluids to the young layer of bark. The fluids so conveyed are quite different from the sap of which we have hitherto been speaking. They possess the peculiar flavour of the plant whatever it may be, and are truly secreted fluid. Here then is a new and most satisfactory theory of vegetation

vegetation offered to our contemplation. The nutritious fluids, imbibed from the foil by the radical fibres, after, poffibly, undergoing fome change equivalent to digeftion, in the body of the root or bafe of the ftem, are conveyed in the ftate of fap along the laft-mentioned organ into the leaves. The fap therefore is the blood of a vegetable, and like that of animals, is nearly fimilar in all. In the leaf it is expofed to the action of light, heat and air, three powerful agents, fufficient to account for the changes it there undergoes. Much of the watery part of its compofition evaporates by perfpiration from the leaf, nor is the main body of the fap returned to the part, whence it was propelled, like blood to the heart, fo that in this fenfe vegetables cannot be ftrictly faid to have a circulation of their fap. That portion of the fap which returns from the leaf, is impregnated with carbon from the atmofphere, fo as to be capable of furnifhing matter of increafe through the bark to the body of the plant, according to the experiments of Du Hamel, Hope and others, and wood is moft plentifully fecreted under the infertion of each leaf, as is apparent from the fwelling obfervable in moft trees thereabouts. Indeed Dr. Hales had fhewn long ago that the bark, when cut afunder, extended itfelf from below a leaf or leaf-bud, and not above it, fee his "Vegetable Staticks," tab. 13.; and every body knows that all the part of a branch above a leaf dies in confequence of being cut.

Nor does the fap acquire in the leaves matter of increafe only. All the peculiar fecretions, by which one plant differs in tafte, fmell, and medical qualities, from another, are firft evolved in thofe organs, though probably perfected in the bark and wood. There originate the acid or alkaline, mucilaginous or refinous, acrid or aromatic, faccharine or bitter principles. How exquifite, then, is the chemiftry of nature, and how fine the ftructure of the vegetable frame, to elaborate and to preferve, in fo fmall a compafs, fuch different and difcordant fecretions! That portion of the fap which is carried to the flower and fruit, undergoes no lefs remarkable changes, for purpofes deftined to be accomplifhed there; nor is it returned from thence, as from the leaves, in order to anfwer any further end. Hence thofe parts, called the organs of fructification, have their own appropriate internal ftructure, as well as external configuration. Their fecretions of colour, fcent and flavour, are generally very diftinct from thofe of the leaves, and even more remarkable.

Now the real fap veffels are known, it feems no longer very difficult to account for the propulfion of fluids along them. The ftimulating effect of thofe fluids, as well as of external heat, upon the living principle of the veffels in queftion, their fpiral ftructure, the agitation of the whole vegetable frame, particularly the leaves, by wind, the great perfpiration of the latter, and confequent fuction of fluids from the veffels that enter their fubftance, are all furely fufficient caufes. Thofe who have hitherto treated the fubject of vegetable phyfiology, have confined their ideas too much either to mechanical or to chemical principles, without taking into confideration the living power by which alone the vegetable, as well as animal functions, can be in any adequate degree explained; and, after all, it muft be confeffed that this vital principle, whofe agency we cannot deny, proves in many inftances rather a refuge for our ignorance, than a fource of information.

One farther obfervation remains to be made, relative to the circulation or propulfion of the fap, that the vafcular fyftem of plants is ftrictly annual, not only in thofe herbs whofe whole exiftence is confined to one fummer, but even in trees and fhrubs. The layer of alburnum, along which the fap runs in the prefent fpring and fummer, is in autumn added to the wood, and foon affimilated to it, while the innermoft layer of bark, along which the returning fap, or rather fecretions, were conveyed, is in like manner added to the bark of preceding feafons, after fecreting materials for a new layer of bark and of alburnum. Thefe in their turn are laid afide; and though they may reafonably be fuppofed to be ftill employed in perfecting the fecretions lodged in their cells, they are out of the main courfe of circulation. The fame thing takes place in the perennial roots of many plants, whofe ftems and leaves are altogether annual. Such roots have many layers, more or lefs diftinctly marked, of wood and bark, and the fecretions which thofe parts contain are often very highly elaborated, as is the cafe with rhubarb, jalap, gentian, bryony, and many others. S.

Circulation *of the fpirits*, or *nervous juice*. That the fpirits circulate is evinced in the fame manner as fome authors choofe to prove the circulation of the blood, *viz.* that as the heart drives out every hour three or four thoufand ounces of blood, whereas ordinarily there are not above two thoufand in the whole body, there is a neceffity for the blood driven out to return to the heart, in order to fupply a fund to be expelled.

In like manner it is fhewn, that there is formed each hour a large quantity of fpirits, which are nothing but the more fubtile parts of this blood driven out from the heart; whence it is inferred that thefe two muft circulate.

The courfe they are fuppofed to take is this. The moft fubtile parts of the arterial blood being carried from the heart to the brain by the carotid arteries, are thrown violently into the fine net-work wherewith the bottom of the ventricles of the brain is lined; whence the more delicate parts are driven into the mouths of the choroid arteries, where they continue their rapid motion, and difcharge themfelves at the pores where thofe veffels terminate around the pineal gland.

Hence they enter that gland, and there form a conftant fpring of fpirits, which, being here purified, enter the cavities of the brain, and infinuating into the pores of its fubftance, flow into the lymphatics, whence they are carried to the heart by two ways; thofe from the upper parts by the fubclavian veins, and the adjacent veffels; thofe from the lower, being difcharged into Pecquet's refervoir, proceed by the thoracic duct, and at laft, by the defcending veins, to the heart, whence they begin their courfe afrefh. See Animal *Spirits*.

Circulation, *fubterranean*. Dr. Plott is one of the many authors who have argued for a fubterranean circulation of water, by means of which many fprings and rivers are fupplied with that water which they give again to the fea. It is probable, indeed, that many of the fmaller fprings are fupplied by rains, only where the country and fituation are favourable; but the larger rivers, and the fprings which fupply them, muft have their origin from fuch a fubterranean circulation, fince all the water that falls in a year in the whole earth, is not one five hundredth part the quantity of that difcharged into the fea at the mouths of rivers, as appears by careful and moderate calculations. There are fome fprings which ebb and flow with the fea; thefe cannot be doubted as to their origin, which is evidently from that body of water whofe motions they are influenced by. Nor is the cafe much lefs clear in regard to thofe lakes which have falt water and fea-fifh in them, and yet have no communication with any fea by any known cut or paffage.

The number of fhell-fifh and parts of fea-animals dug up in feveral places, at great depths within land, are alfo urged by fome as proofs of fuch fubterranean paffages of the fea-water; but thefe are too univerfally diftributed through

through the ſtrata of the earth to have been brought in this manner, and are therefore rather ſuppoſed to be owing to the great change made in the earth by the flood in the days of Noah. See VAPOUR, &c.

CIRCULATION, in *Chemiſtry*, is an operation whereby the ſame vapour, raiſed by fire, falls back, to be returned and diſtilled ſeveral times, and thus reduced into its moſt ſubtile parts.

Circulation is performed by diſpoſing the liquor in a ſingle veſſel, ſtopped at top, called a *pelican;* or in a double veſſel conſiſting of two pieces, luted on each other; the lower to contain the liquor and its vapours.

It is performed either by the heat of a lamp or that of aſhes, or of ſand moderately hot, or in dung, or by the ſun. It uſually demands a continued heat of ſeveral days, ſometimes of ſeveral weeks, or even ſeveral months. By circulation, the fineſt part of the fluid mounts to the top of the veſſel, and finding no iſſue there, falls back again, and rejoins the matter left behind at the bottom, whence it aroſe; and thus by continuing to riſe and fall alternately in the veſſel, there is effected a kind of circulation or remixtion of the ſpirituous parts with the groſs ones, whereby the former is rendered finer and more ſubtile, and are better diſpoſed to exert their activity when ſeparated from the latter.

CIRCULATION, in *Commerce*, denotes that reciprocal interchange of goods, money, or paper, by which the political and trading intereſts of a country are conducted and promoted.

Accordingly, ſome writers have repreſented it as the grand baſis on which the whole edifice of modern political economy reſts; as that which characterizes and diſtinguiſhes this ſyſtem of political economy from all others; and as that which determines and meaſures the population, the riches, the credit, the proſperity, and the power of nations; inſomuch that the degree of and facility of circulation being given, the degree of population, of riches, of credit, of proſperity, and of power, are neceſſarily given at the ſame time.

Dr. Smith, in his "Nature and Cauſes of the Wealth of Nations" (vol. i p. 485), obſerves, that the circulation of every country may be conſidered as divided into two branches: the circulation of the dealers with one another, and the circulation between the dealers and the conſumers. Although the ſame pieces of money, whether paper or metal, may be employed ſometimes in the one circulation, and ſometimes in the other, yet as both are conſtantly going on at the ſame time, each requires a certain ſtock of money of one kind or another to carry it on. The value of the goods circulated between the different dealers, never can exceed the value of thoſe circulated between the dealers and the conſumers: whatever is bought by the dealers being ultimately deſtined to be ſold to the conſumers. The circulation between the dealers, as it is carried on by wholeſale, requires generally a pretty large ſum for every particular tranſaction. That between the dealers and the conſumers, on the contrary, as it is generally carried on by retail, frequently requires but very ſmall ones; a ſhilling, or even a halfpenny, being often ſufficient. But ſmall ſums circulate much faſter than large ones. A ſhilling changes maſters more frequently than a guinea, and a halfpenny more frequently than a ſhilling. Conſequently, though the annual purchaſes of all the conſumers are at leaſt equal to thoſe of all the dealers, they can generally be tranſacted with a much ſmaller quantity of money; the ſame pieces, by a more rapid circulation, ſerving as the inſtrument of many more purchaſes of the one kind than of the other. Paper-money may be ſo regulated, as either to confine itſelf very much to the circulation between the different dealers, or to extend itſelf likewiſe to a great part of that between the dealers and the conſumers. When bank-notes are iſſued of a conſiderable value, *e. g.* of 10*l.*, paper-money confines itſelf very much to the circulation between the dealers. The conſumer is obliged to change it in the purchaſe of a ſmall quantity of goods, *e. g.* the worth of 5*s.* It often returns into the hands of a dealer before the conſumer hath ſpent the fortieth part of the money. But where bank-notes are iſſued for ſo ſmall ſums as 20*s.*, paper-money extends itſelf to a great part of the circulation between dealers and conſumers. By the mode of iſſuing for the purpoſe of circulation, bank-notes for very ſmall ſums, people of little real property are enabled and encouraged to become bankers: and the frequent bankruptcies to which ſuch mean bankers are liable, may occaſion a very conſiderable inconvenience, and ſometimes even a very great calamity to many poor people who had received their notes in payment. Dr. Smith ſuggeſts, that it might be better if no bank-notes were iſſued in any part of the kingdom for a ſmaller ſum than five pounds. Paper-money, he ſays, would then confine itſelf in every part of the kingdom to the circulation between the different dealers; and when this is the caſe, there will be always plenty of gold and ſilver. But when it extends itſelf to a conſiderable part of the circulation between dealers and conſumers, it baniſhes gold and ſilver almoſt entirely from the country; almoſt all the ordinary tranſactions of its interior commerce being then carried on by paper. Neverthelefs, though paper-money ſhould be pretty much confined to the circulation between dealers and dealers, yet bankers might ſtill be able to give nearly the ſame aſſiſtance to the induſtry and commerce of the country, as they would do if paper-money filled almoſt the whole circulation. The ready money which a dealer is obliged to keep by him for anſwering occaſional demands, is deſtined altogether for the circulation between himſelf and other dealers of whom he buys goods. He has no occaſion to keep any by him for the circulation between himſelf and the conſumers, who are his cuſtomers, and who bring ready-money to him, inſtead of taking any from him. Though no paper-money, therefore, was allowed to be iſſued but for ſuch ſums as would confine it pretty much to the circulation between dealers and dealers, yet, partly by diſcounting real bills of exchange, and partly by lending upon caſh accounts, banks and bankers might ſtill be able to relieve the greater part of theſe dealers from the neceſſity of keeping any conſiderable part of their ſtock by them unemployed, and in ready money, for anſwering occaſional demands. They might ſtill be able to give the utmoſt aſſiſtance which banks and bankers can with propriety give to traders of every kind. See BANK, COMMERCE, CREDIT, MONEY, and PAPER-MONEY.

CIRCULATORY, CIRCULATORIUM, in *Chemiſtry*, the veſſel wherein a fluid is put to undergo the proceſs of CIRCULATION.

There are two kinds of *circulatories;* the *diota*, or DOUBLE *veſſel;* and the PELICAN.

CIRCULUS, in *Geometry*, *Logic*, &c. See CIRCLE.

CIRCULUS, among *Chemiſts*, is a round iron inſtrument, uſed in cutting off the necks of glaſs veſſels; which they effect thus: The inſtrument, being heated, is applied to the glaſs veſſel, and there kept till the latter grows hot; then, by a few drops of cold water, or a cold blaſt thereon, it flies even and regularly off. Thus they cut off the necks of retorts, or cucurbits.

There is another method of doing the ſame; *viz.* by tying a thread, firſt dipped in oil of turpentine, round the place where the ſection is to be; and then ſetting fire to the thread. This done, ſome cold water being ſprinkled on the

the place, the glafs will be cracked through that part precifely where the thread was tied.

CIRCUMAGENTES *mufculi*, in *Anatomy*. See OBLIQUUS.

CIRCUMAMBIENT, an epithet denoting a thing to inveft, or incompafs another round. Thus, we fay, the ambient, or circumambient air, &c.

CIRCUMCELLIONES, in *Church Hiftory*, a fet of illiterate favage peafants, and defperate ruffians, who adhered to the party of the DONATISTS towards the end of the fourth century. They affumed the title of vindicators of juftice, and protectors of the oppreffed, and maintained their caufe by force of arms, and filled the whole province of Africa with flaughter and rapine. Conftantine the Great, in order to quiet the tumults which they occafioned, abolifhed the laws that had been enacted againft the Donatifts; however, after his death, their affaffinations and maffacres were renewed, till they were defeated by Macarius at the battle of Bagnia. Many of this frantic mob were afterwards treated with great feverity, and the Donatifts fhared their fufferings.

CIRCUMCISION, the act of cutting off the prepuce; or a ceremony, in the Jewifh and Mahometan religions, wherein they cut away the forefkin of the males who are to profefs the one or the other law.

Circumcifion commenced in the time of Abraham; and was, as it were, the feal of a covenant ftipulated between God and him: it was in the year of the world 2107, of the Julian period 2817, B.C. 1897, that Abraham, by divine appointment, circumcifed himfelf, and all the males of his family; from which time it became an hereditary practice among his defcendants.

This appointment (fee Gen. xvii. 9, &c.) was accompanied with a further injunction, that for the future all males born of him, or in his family, whether bond or free, fhould be circumcifed on the 8th day after the birth, and alfo a declaration, that if any male remained uncircumcifed, that perfon fhould be cut off, as a defpifer of God's covenant, from having any fhare in the promifed land defigned for him and his pofterity.

This ceremony, however, was not confined to the Jews: Herodotus and Philo Judæus have obferved, that it obtained alfo among the Egyptians and Ethiopians. Herodotus fays, (lib. ii. c. 91.) that the cuftom was very ancient among each people; fo that there was no determining which of them borrowed it from the other. Among the Egyptians, he fays, it was inftituted ἀπ' ἀρχῆς, from the beginning; by which expreffion, as Shuckford intimates (Conn. vol. i. p. 324.) he could not mean, from the firft rife or original of that nation, but that it was fo early among them, that the Heathen writers had no account of the original of it. When any thing appeared to them to be thus ancient, they pronounced it to be ἀπ' ἀρχῆς. That Herodotus himfelf meant no more than this by the expreffion is evident from his own words. For we find him querying, whether the Egyptians learnt circumcifion from the Ethiopians, or the Ethiopians from the Egyptians, and he leaves the queftion undecided, merely concluding that it was a very ancient rite, (lib. ii. c. 104.) There had been no room for this hefitation and indecifion, if he had before meant, that it was an original rite of the Egyptians when he faid it was ufed by them "from the beginning." But among the Heathen writers, to fay a thing was ἀπ' ἀρχῆς, "from the beginning," or that it was "very anciently" practifed, are terms perfectly fynonymous, and mean the fame thing.

The fame hiftorian relates, that the inhabitants of Colchis alfo ufed circumcifion; whence he concludes, that they were originally Egyptians. He adds, that the Phœnicians and Syrians, who lived in Paleftine (*i. e.* as Jofephus rightly corrects him, (Cont. Apion.) the Jews) were likewife circumcifed; but that they borrowed the practice from the Egyptians. And, laftly, that a little before the time when he wrote, circumcifion had paffed from Colchis, to the people inhabiting near Thermodoon and Parthenius.

Diodorus Siculus (lib. i.) thought the Colchians and the Jews to be derived from the Egyptians, becaufe they ufed circumcifion. And again he fays (lib. iii.), fpeaking of fome other nations, that they were circumcifed, after the manner of the Egyptians. Sir John Marfham is of opinion, that the Hebrews borrowed circumcifion from the Egyptians; and that God was not the firft author thereof; citing Diodorus Siculus, and Herodotus, as evidences on his fide. This latter propofition feems directly contrary to the teftimony of Mofes, who affures us, (Gen. xvii.) that Abraham, though ninety-nine years of age, was not circumcifed till he had the exprefs command of God for it.

Celfus and Julian, as we learn from Origen and Cyril, adopted the opinion, avowed by Marfham; and lord Shaftefbury in his "Characteriftics," (vol. iii. p. 52.) has alfo expreffed his fentiments to the fame purpofe. As to the teftimonies of Herodotus and Diodorus, they cannot be held in very high eftimation, if we confider, that the Heathen writers in general were very imperfectly and partially acquainted with the Jewifh hiftory. In the books of Jofephus (Cont. Apion) we have many inftances of their errors and mifreprefentations with regard to the hiftory of the Jews; and the account which Juftin, the epitomizer of Trogus Pompeius, gives of their original, (Juftin. lib. xxxvi. c. 2.) evidently fhews, that they were but very fuperficially acquainted with Jewifh affairs. Accordingly, Origen might juftly blame Celfus for adhering to the Heathen accounts of circumcifion in preference to that of Mofes; for Mofes has given a clear and full account of the original of the inftitution, whilft they only afford us imperfect hints and conjectures. Befides, we have (fays Shuckford) the teftimony of an Heathen writer unqueftionably confirming Mofes's account of Abraham's circumcifion. We read in Philo Biblius's extracts from Sanchoniathon (apud Eufeb. Præp. Evang. lib. i. c. 10.) of a record in the Phœnician antiquities, that Ilus, who was alfo called Chronus, circumcifed himfelf, and compelled his companions to do the fame. This Ilus, or Chronus, according to fir John Marfham, was Noah, or at leaft, as other writers fuggeft, he was a perfon much more ancient than the times of Abraham; and therefore they infer from this paffage, that circumcifion was practifed before the time of Abraham. To this argument, however, it may be replied, that the fame author who gives us this account of Ilus, or Chronus, fufficiently informs us who he was, by telling us that he facrificed his only fon; and we are further informed, with refpect to this Chronus, from the Egyptian records, that the Phœnicians called him Ifrael. Chronus, therefore, or Ifrael, who was reported to have facrificed his only fon, can be no other perfon than Abraham, who is reprefented by the Heathen writers as having facrificed his only fon Ifaac. Jacob was, indeed, the perfon who was called Ifrael; but the Heathen accounts afcribe to him 10 fons; and here we have only a trivial miftake compared with many others which occur in the Heathen hiftories; or that of applying the name Ifrael to the perfon, who, as they fay, facrificed his only fon, when the name really belonged to his grandfon. From this paffage, therefore, it appears, not as fome writers would infer from it, that circumcifion was ufed in Heathen nations for ages before Abraham, but that Abraham and his family were circumcifed;

cumcifed; and, therefore, unlefs they can produce a teftimony of fome other perfons being circumcifed, cotemporary with, or prior to, Abraham, we have their own confeffion that Abraham was circumcifed at an earlier period than that in which they can produce an inftance of any other perfon's being circumcifed in the world. Moreover, it has been alleged, that the Philiftines, who were originally Egyptians, and gave name to the country, were circumcifed: and if we may be allowed to refer to the rabbinical commentators on this fubject, they pretend that one of the three proofs, which Jofeph gave to the patriarchs of his being their brother (fee Gen. xlv. 12.), was the token of circumcifion, which, as they fay, was peculiar at that time to the family of Abraham. This he is fuppofed to have difcovered, by unfolding his garment, when they ftood near him, and bidding them regard it. Jofeph's "caufing every man to go out (v. 1.) and praying his brethren to come near him," (v. 4.) feems to intimate, that he had fome important fecret to impart to them, a fecret which was not to be expofed to the ridicule or wanton curiofity of the uncircumcifed Egyptians. Otherwife there appears to be nothing, in this whole narration, which is told with fo much elegance and fimplicity, that could in any manner offend, or which, indeed, would not rather have afforded the greateft pleafure and fatisfaction to the Egyptians. (See Shaw's Travels, p. 390.) It feems alfo to be implied (Jerem. ix. 25, 26.) that the Egyptians were not circumcifed at the time when that prophet lived, *viz.* about 627 years before Chrift, which was not 200 years before Herodotus flourifhed and wrote his hiftory.

Dr. Spencer, in his learned work "De Legibus Hebræorum, &c." (lib. i. c. 5.) diftinguifhes between patriarchal and Mofaic circumcifion: the former was in ufe before the law, and fealed the covenant between God and Abraham, as well as his pofterity: the latter derived a kind of new fanction from the Mofaic law, and was deemed a primary ceremony of the Jewifh religion. He confiders the defign and ufe of this inftitution, partly as a *fign*, and partly as a *feal*. As a *fign*, it ferved to diftinguifh and difcriminate the people of God, and particularly the pofterity of Abraham, from whofe line the Meffiah was to proceed, from other nations; it was alfo a memorial of the covenant between God and Abraham; it figuratively denoted the purity and fanctity which pertained to the character of thofe who fuftained a relation to God; it was alfo a token of initiation, by which perfons were introduced into the Jewifh church, and devoted themfelves to the worfhip of Jehovah; it was a kind of prophylactic, or prefervative fign, which intimated the providential protection in which the Jews were peculiarly interefted; and it was a political fign, by which profelytes were admitted into the commonwealth of Ifrael, and a participation of the external privileges and honours pertaining to the Jewifh people. Circumcifion, as a *feal*, ferved to indicate and to ratify the covenant fubfifting, under the patriarchal difpenfation, between God and the defcendants of Abraham, and, under the Mofaic economy, between God and the Jewifh people. On the part of God, it betokened and enfured the grant of peculiar bleffings, and on the part of men, abftinence from idolatry, and a ftedfaft adherence to the worfhip and fervice of Jehovah. This learned writer proceeds to enumerate a variety of reafons, natural, moral, and ceremonial, for the particular mode in which this rite was performed, and he intimates that at the time of its performance it was ufual to give a name to thofe who were the fubjects of it. In an elaborate inquiry concerning the origin and antiquity of this rite, he ftates the arguments for and againft its derivation from the Egyptians; and without abfolutely determining the queftion, he feems to incline to the opinion adopted by fir John Marfham and others. The evidence, however, as we have already obferved, feems to preponderate on the other fide; and it is generally allowed that the practice of circumcifion, among the Hebrews, differed very confiderably from that of the Egyptians. Among the firft it was a ceremony of religion, and was performed on the eighth day after the birth of the child: among the latter, it was a point of mere decency and cleanlinefs; and, as fome will have it, of phyfical neceffity; and was not performed till the thirteenth year; and then on girls as well as boys.

Among the Jews, circumcifion was performed with a knife made of fome kind of ftone, as being thought lefs dangerous than other inftruments of iron or fteel. But nothing is ordained, in the original inftitution of this rite, with refpect to the perfon by whom, or with what inftrument, or in what manner the ceremony was to be performed; only that the forefkin fhould be cut off on the eighth day; fo that it was left to the option of the parent, either to perform it himfelf, or to employ fome other perfon, either a prieft, a furgeon, or a friend. In this laft capacity, it was confidered as a high compliment to be chofen to that office. The ceremony, the mode of performing which it is needlefs minutely to defcribe, was ufually accompanied with great rejoicing and feafting; and it was at that time, as we have already obferved, that the child was to be named by the parents, in the prefence of the company. Thefe names were generally fignificant of fomething relating to the parents or the child, or to fome other circumftances of time or place. The Ifraelites fet afide the practice of circumcifion, during the forty years of their paffage through the wildernefs; becaufe, as fome have argued, circumcifion being intended as a mark of diftinction between the Jews and the Gentiles, it was not neceffary to make any mark at all, in a place wherein there was nobody to mix with them. Other reafons, however, have been affigned for the difcontinuance and revival of this rite, of which it will be proper to give fome account. After the Ifraelites had paffed the river Jordan, Jofhua encamped at Gilgal, on the eaft fide of Jericho, and here God directed him to revive the right of circumcifion; for the Ifraelites had circumcifed none of their children that were born, after the exit from Egypt, until this time. In order to account for this neglect, it has been alleged, that the covenant which the Ifraelites made with God at Horeb was to do and obferve all the things which the Lord fhould command them (fee Exod. xix. 8. xxiv. 3. 7. Deut. v. 27. xxvi. 17.); and they were to avoid the introduction of any religious rite, without a divine command: and, therefore, though God had ordered Abraham to circumcife himfelf and children, and to enjoin the ufe of this rite on his pofterity; yet, when God was giving to the Ifraelites a new law by the inftrumentality of Mofes, they could not warrantably affume any rite, however ancient or cuftomary, as a part of it, unlefs God himfelf gave them a command for it. God, indeed, had given them a command for circumcifion. We find it among the laws given after the death of Nadab and Abihu, the fons of Aaron (Lev. xii. 3.), who were killed by fire from the Lord, for offering incenfe in a manner which he did not command (Lev. x. 1.); and this incident muft ferve as admonition to the people not to mingle any of their own fancies in the performance of any divine inftitutions, and rendered them particularly cautious in every matter of this kind. Although the paffover was a feaft which they were commanded to obferve throughout their generations by a perpetual ordinance (Exod. xii. 14.); yet we find that they

they did not attempt a second celebration of it, without an express command from God for the purpose (Numb. ix. 1, 2, 3. 7.); nor did they venture to proceed in a case of doubt, which occurred in relation to the men, who were defiled by a dead body, but waited till Moses heard what the Lord would command concerning them. (Numb. ix. 6, 7, 8.) Thus also, as the law for circumcision required the males to be circumcised at the age of eight days (Lev. xii. 3.), and was not given till within the second year of the Exodus, when there must have been in the camp a great number of children uncircumcised, who were past the day of age at which this rite was to be performed, a doubt would arise, when or how these were to be put "under the law;" and as the Israelites did not receive directions from God how to act, they might reasonably hesitate in proceeding without special instruction. The reader, who consults Poli Synops. Critic. in loc. will find various reasons assigned by critics and commentators for the omission of circumcision during the period already noticed. But Shuckford, (see his Conn. of Sacred and Prophane Hist. vol. ii. p. 156.) thinks they have not succeeded in assigning the true one. We find (he says) no fault imputed to the Israelites for their neglect of it, and God himself now "rolled away the reproach of Egypt from off them," (Josh. v. 9.); so that the Israelites had long esteemed it a reproach to them, that they did not practise this rite; but it had been their misfortune, that God had not yet given them orders how or when to begin it, and, therefore, they were under a necessity of living in the omission of it. Shuckford suggests that the expression here used has been misunderstood. A state of circumcision is called the "reproach of Egypt," that is, as some say, the Egyptians thought it a reproach to them who lived in it: and, indeed, it is necessary to take the words in this sense, if we would infer from them that circumcision was originally an Egyptian rite, and that the Hebrews learned from them the use of it. But the writer, whose observations are now cited, is of opinion, that the true meaning of the expression "the reproach of Egypt," is directly contrary to the sense which these writers would give to it. "My reproach," "my shame," "my dishonour," (see Gen. xxx. 23. 2 Sam. xiii. 13. Ps. lxix. 19.) do all signify, not what I may have to impute to others, but what others may object to me; and, in like manner, "reproach of Egypt," or "Egyptian reproach," signifies not what the Egyptians might think a disrepute to others, but what other nations esteemed a blemish and defect in them. We find an expression of like import thus used by one of the most elegant classics. (See Hor. Carm. l. iv. od. 12.) The swallow is said to be

> "—— Cecropiæ domûs
> Æternum opprobrium,"

the "everlasting reproach of the house of Cecrops," not as hinting any thing, for which the descendants of Cecrops might reproach others; but upon account of facts that were a lasting dishonour to this family. Thus also, they were not the Egyptians at this time, but the Israelites, who thought uncircumcision a disreputable thing, and accounted all nations profane, that did not use this institution; and the Egyptians at this time, not observing this rite, this, in the judgment of the Israelites, was their reproach, a thing opprobrious or disgraceful to them: and, therefore, when God here appointed the Israelites to be circumcised, he "rolled away the reproach of Egypt from off" them; he removed from them that state of uncircumcision, which they thought an infamous defect in the Egyptians. With regard to the revival of circumcision by Joshua, our author makes the two following observations; the first is, that the Israelites must hence derive full conviction that all their fathers were dead, against whom God had denounced, that their carcases should fall in the wilderness (Numb. xiv.); for, upon this renewal of circumcision, none having been circumcised from the time of the Exodus till now (Josh. v. 5.), it became evident how many of the camp had been in Egypt; and, by computing the age of those who had been there, it would appear, that no persons were then alive except Caleb and Joshua, who were twenty years old, when the poll was taken in the year after the Exodus. (Numb. xxvi. 64, 65.) Secondly, as the Israelites were now in an enemy's country, in the neighbourhood of a powerful and populous city, and could not be secure for one day, that the Canaanites might not attempt to march against them, Joshua, without an express order from God, could never have thought this a proper time to disable any part of the camp by circumcising them; and, therefore, he must certainly have had a command from God to this purpose.

M. Fleury observes, that the Jews were not unanimous as to the necessity of circumcision; some holding it an essential, others only as a circumstance.

Among the Jews, the father is obliged to have his son circumcised on the eighth day; it may not be sooner: but the child's weakness may allow of its being deferred longer. There is a god-father to hold the child, and a god-mother to carry it from the house to the synagogue, and to present it there. He who circumcises is called in Hebrew *Mohel;* any person is chosen for the purpose indifferently, provided he be but capable of the function, which, among the Jews, is a title of great merit. The manner of the ceremony, as related by Leo de Modena, is as follows.—Two seats are prepared in the morning with silken cushions, one for the god-father, who holds the child, the other, as they say, for the prophet Elias, whom they suppose to assist invisibly. The person who is to circumcise brings the necessary utensils; the razor, styptic, linen, fillet, and oil of roses; to which some add a shell full of sand, to put the preputium in. A psalm is sung till the god-mother brings the child, attended with a crowd of women, and delivers it to the god-father, none of them entering the door: the god-father, being seated, sets the child on his lap; then the circumciser, taking the razor, and preparing the child for the operation, says, "Blessed be thou, O Lord, who hast injoined us circumcision," and in so saying cuts off the thick skin of the preputium, and with his finger-nails tears off another finer skin remaining, sucking the blood two or three times, as it breaks out, and spitting it out into a glass full of wine; then he lays dragon's blood on the wound, with powder of coral, and other things, to staunch the blood; and lastly, a compress of oil of roses; and thus binds up the whole: this done, he takes a glass of wine, and, blessing it, adds another benediction for the child, and imposes the name.

Circumcision, though it be not so much as once mentioned in the Koran, is yet held by the Mahometans to be an ancient divine institution, confirmed by the religion of Islam, and though not so absolutely necessary but that it may be dispensed with in some cases, yet highly proper and expedient. The Arabs used this rite for many ages before Mahomet, having probably learned it from Ismael, though not only his descendants, but the Hamyarites, and other tribes, practised the same. The Ismaelites, we are told (Joseph. Ant. b. i. c. 23.), used to circumcise their children, not on the 8th day, according to the custom of the Jews, but when about twelve or thirteen years old, at which age their father underwent that operation (Gen. xvii. 25.): and the Mahometans imitate them so far as not to circumcise children before they be able,

 at

at leaſt, diſtinctly to pronounce that profeſſion of their faith, "There is no God, but God, Mahomet is the apoſtle of God;" but they fix on what age they pleaſe for the purpoſe between ſix and ſixteen. Although the Moſlem doctors are generally of opinion, conformably to the Scripture, that this precept was originally given to Abraham, yet ſome have imagined that Adam was taught it by the angel Gabriel, to ſatisfy an oath he had made to cut off that fleſh, which, after his fall, had rebelled againſt his ſpirit; whence an odd argument has been drawn for the univerſal obligation of circumciſion (See the apocryphal Goſpel of Barnabas, c. 23.). It cannot be ſaid, indeed, that the Jews took the lead of the Mahometans in this way, yet they ſeem ſo unwilling to believe any of the principal patriarchs or prophets before Abraham were really uncircumciſed, that they even pretend ſeveral of them, as well as ſome holy men who lived after his time, were born in a circumciſed ſtate, or without a foreſkin; and that Adam, in particular, was ſo created; whence the Mahometans affirm the ſame thing of their prophet; but as the practice was in uſe among the Arabs long before, the prophet muſt have been circumciſed many years prior to his pretended miſſion. See "Pocock, Spec." and "Abulfed. Vit. Mahom." cited by Sale in the Preliminary Diſcourſe to the Koran. Among the Mahometans they have a tradition, that their prophet declared circumciſion to be a neceſſary rite for men, and for women honourable. This tradition makes the prophet declare it to be "Sonna," which Pocock renders a neceſſary rite, though Sonna, according to the explanation of Reland, does not comprehend things abſolutely neceſſary, but ſuch as, though the obſervance of them be meritorious, the neglect is not liable to puniſhment. Aſſemani aſſerts, that the Turkiſh children receive their name at the inſtant of circumciſion, as the children of Chriſtians do at baptiſm: and with reſpect to the circumciſion of Chriſtian proſelytes, that they are previouſly obliged to trample and ſpit three times on a croſs preſented to them for that purpoſe, and then three arrows being ſhot off into the air by three of the attendants, the name of the new convert is pronounced before the arrows fall to the ground. "The two laſt circumſtances," ſays Dr. Ruſſell (Hiſt. of Aleppo, vol. i. p. 407.), are unknown at Aleppo; and the firſt is certainly a miſtake; for the child is named almoſt as ſoon as it comes into the world; and at Conſtantinople alſo, the naming of the child is not deferred till the time of circumciſion. The circumciſion of females is not known at Aleppo; and Dr. Ruſſell is of opinion, that circumciſion is not abſolutely neceſſary in that climate on a phyſical account; nor does it appear to prevent any inconveniences which might not be obviated by leſs violent means. At Aleppo the boys are circumciſed between the age of ſix and ten, ſometimes later, but very ſeldom earlier. From that period their heads are ſhaved, and they aſſume the turban, inſtead of the handkerchief, which they wore during infancy. The ceremony is performed at the father's houſe, where noiſy rejoicings are made for ſeveral days. The boy receives preſents from his kindred, as well as from others who have been invited to the feaſt. He is dreſſed in new clothes, his turban is decked with flowers and tinſel, and for five or ſix days he wears a kind of large ſilk apron faſtened upon one ſhoulder, as a badge of the operation he has undergone. In this dreſs he is led on horſeback, in proceſſion through the ſtreets, preceded by the caſtle-muſic and ſeveral men armed with ſcymitars and ſhields. A number of female relations cloſe the proceſſion, and, after every ſtop made for the mock champions to combat, the women ſhout in their uſual manner while the men huzza. It is cuſtomary for people of condition to have two or three of their dependants' children circumciſed at the ſame time, which adds to the pomp of the cavalcade. Sonnini (ſee his "Travels in Upper and Lower Egypt," p. 337), deſcribes proceſſions on a ſimilar occaſion, which he frequently witneſſed in the ſtreets of Siout.

The Turks, before the operation of circumciſion, ſqueeze the ſkin with little pincers, to deaden the ſenſation; they then cut it off with a razor, and apply a certain powder which heals the wound and takes off the pain. They never circumciſe till the ſeventh or eighth year, and ſometimes the eleventh or twelfth, as having no notion of its being neceſſary to ſalvation.

The manner of circumciſing among the Turks differs from that of the Jews; for the former, after they have cut off the ſkin, meddle no farther; but the laſt tear off the edge of the remaining ſkin in ſeveral places with their thumb-nails, which is the reaſon why the circumciſed Jews are cured much ſooner than the Turks.

Thoſe among the Jews who perform the operation of circumciſion are diſtinguiſhed by the length of their thumb-nails.

The Perſians circumciſe their children ſometimes within ten days after their birth, and ſometimes at ten years of age: that of girls is unknown: the wound is healed with cauſtic or aſtringent powders; and burnt paper is very generally uſed, which, according to Chardin, is the beſt remedy. This author tells us, "that the operation, when performed on grown perſons, is attended with conſiderable pain; that they are obliged to confine themſelves to the houſe for three or four weeks, and that death is ſometimes the conſequence."

Thoſe of Madagaſcar cut off the fleſh at three ſeveral times, and the moſt zealous of the relations preſent catches hold of the preputium and ſwallows it.

In the Maldivia iſlands, children are circumciſed at the age of ſeven years. In order to render the ſkin ſoft, the children are bathed in the ſea ſix or ſeven hours before the operation.

Herrera tells us, there is a kind of circumciſion among the Mexicans, though they are very far both from Judaiſm and Mahometaniſm; they cut off the foreſkin of the virile member, and the ears, as ſoon as the child is born, with great ceremony.

Among all the nations ſeated on the genuine Maranon in America, circumciſion is practiſed among the men, and exciſion among the women. Among the latter it is uſed at the age of ſeven, eight, or nine years, as in Arabia.

There is a kind of circumciſion practiſed at Otaheite, one of the newly diſcovered iſlands in the South Seas. The operation is performed by a prieſt, and conſiſts in ſlitting the prepuce through the upper part, to prevent its contracting over the glans. The practice ſeems to have taken its riſe from motives of cleanlineſs. Hawkeſworth's Voyages, vol. ii. p. 241.

Circumciſion is very generally practiſed in Abyſſinia, (ſee Abyssinia.) The Abyſſinians have a tradition among them, which merits ſome conſideration in the inquiry into the origin of this rite; *viz.* that they were, in the earlieſt time, circumciſed, before they left their native country and ſettled in Tigré. On this point Mr. Bruce obſerves, that if circumciſion was originally a Jewiſh invention, it ſeems very extraordinary, that all thoſe nations to the ſouth ſhould be ignorant of it, while others towards the north were ſo early acquainted with it: for none of thoſe nations up the Nile (except the ſhepherds) either know or practiſe it to this day; though, ever ſince the 1400th year before Chriſt, they have been in the cloſeſt connection with the Jews. Hence this writer infers, that the rite of circumciſion migrated northward from the plain of Mamre, for it certainly

made

made no progrefs fouthward from Egypt. As many nations contiguous to Egypt never received circumcifion from it, it feems, fays Mr. Bruce, an invincible argument, that this was no endemial rite or cuftom among the Egyptians; and it was of no ufe to this nation, as the reafons mentioned by Philo and others, of cleanlinefs and climate, are abfolute dreams, and are now exploded; and that they are fo is plain, becaufe otherwife, the nations more to the fouthward would have adopted it, as they have univerfally done the cuftom of female circumcifion, which Mr. Bruce calls "excifion." Circumcifion then, fays this author, (Travels, vol. iii. p. 346.) having no natural caufe or advantage, being in itfelf repugnant to man's nature, and extremely painful, if not dangerous, could never originate in man's mind wantonly and out of free-will. It might have done fo indeed from imitation, but with Abraham it had a caufe, as God was to make his private family in a few years numerous, like the fands of the fea. This mark, which feparated them from all the world, was an eafy mode of fhewing whether the promife was fulfilled or not. They were going to take poffeffion of a land where circumcifion was not known, and this fhewed them their enemy diftinct from their own people. And it would be the groffeft abfurdity to bind Sampfon to bring, as tokens of the flain, fo many forefkins or prepuces of the Philiftines, if, as Herodotus fays, the Philiftines had cut off their prepuces a thoufand years before.

Circumcifion among the ancient Egyptians was confidered as indifpenfable. Whether it was really fo in their climate, Sonnini (Travels in Upper and Lower Egypt, p. 263.) does not undertake to refolve; although he thinks, that if it be not altogether neceffary, it is at leaft of very great utility among a rude and flovenly people. It is likewife in ufe among the Copts, who, not thinking themfelves fufficiently fure of admittance into paradife by virtue of the baptifm they receive as Chriftians, reckon it alfo neceffary to fubmit to circumcifion, following, in this refpect, as well as in feveral others, the precepts of the religion of the Mahometans, among whom they live.

In Egypt circumcifion is not peculiar to the men; but the women alfo undergo one of a fomewhat fimilar nature. This fort of circumcifion, called indeed by Bruce "excifion," as we are informed by Strabo (lib. xvii.), was practifed by the people of ancient Egypt. He fays, the Egyptians circumcifed both men and women "like the Jews." It does not appear that any fuch operation ever obtained among the Jewifh women; nor is it any where pretended to have been a religious rite, but to be introduced from neceffity, in order to avoid a deformity to which nature has fubjected particular perfons, in particular climates and countries. All the Egyptians, as Mr. Bruce informs us, the Arabians, and nations to the fouth of Africa, the Abyffinians, Gallas, Agows, Gafats, and Gongas, make their children undergo this operation, at no fixed time, indeed, but always before they are marriageable. Belon fays the practice prevailed among the Coptæ; and P. Jovius and Munfter fay the fame of the fubjects of Prefter John.

The greater number of thofe who have written on the practice of female circumcifion, have confidered it as the retrenchment of a portion of the nymphæ, which are faid to grow, in the countries where the practice obtains, to an extraordinary fize. Others have imagined that it was nothing lefs than the amputation of the clitoris, the elongation of which is faid to be a difgufting deformity, and to be attended with other inconveniences, which rendered the operation neceffary.

Sonnini fays, that before he had an opportunity of afcertaining the nature of the circumcifion of the Egyptian women, he imagined it confifted in the amputation of the excrefcence of the nymphæ or of the clitoris, according to circumftances, and according as thefe parts were more or lefs elongated. He adds, that it is even very probable, that thefe operations take place not only in Egypt, but likewife in feveral countries of the Eaft, where the heat of the climate, and other caufes, may produce too great an increafe of thefe parts. This author, fufpecting that there muft be fomething more than an excefs in thofe parts, an inconvenience, which, far from being met with in all women, could alone have given rife to an ancient and general practice, determined to fubmit the matter to the teft of experience. Having examined a young girl of Egyptian origin, about 8 years old, he found a thick, flabby, and flefhy excrefcence, covered with fkin, which grew from above the commiffure of the labia and hung down it about half an inch. In fize and fhape it refembled the caruncle pendent from the bill of a turkey-cock. This fingular excrefcence was cut off by a female operator, without giving much pain to the patient, and without touching either the nympha or the clitoris, which parts were not vifible. The only topical application was a pinch of afhes, although the wound difcharged a confiderable quantity of blood. This operation feems to be neceffary, as this fort of elongated caruncle increafes in proportion to a girl's age, and if fuffered to remain, would entirely cover the os externum. The excrefcence now defcribed is peculiar to women of Egyptian origin, all others, according to Sonnini, being exempt from it, though belonging to nations that are fettled in the country, and in a manner naturalized. The operation is commonly performed on the Egyptian girls at the age of 7 or 8 years. The women of the Saïd are thofe who are accuftomed to perform the operation; and they go about the towns and villages, crying in the ftreet, "circumcifor! who wants a circumcifor?" A fuperftitious tradition has fixed the period in which circumcifion is to be practifed, at the commencement of the increafe of the Nile. In this excrefcence, which is a diftinguifhing characteriftic of the women indigenous in Egypt, we may difcover fome refemblance of that which is peculiar to the inhabitants of the other extremity of Africa. Indeed there is reafon for believing, that this appendage is not reftricted to the Egyptian women only, but extends from their country as far as the Cape of Good Hope, by a line which includes merely the tawny women, and not the female negroes, who have no fuch characteriftic.

Circumcision, in *Surgery*, is an operation to which practitioners have recourfe on feveral emergencies, *viz.* when the prepuce is fo much elongated as to become inconvenient;—when it is clofely contracted, fo as not to admit a free difcharge of the urine;—when there is an ulcer or excoriation under the prepuce, requiring the ufe of fome medicated application, and which cannot be done without removing the forefkin;—when warty excrefcences are formed in a confiderable quantity around the glans penis;—or, when the prepuce itfelf becomes fo altered in its ftructure as to threaten more ferious confequences than would arife from its excifion.

In females, efpecially thofe refiding in hot countries, the preputium clitoridis is often fo much enlarged as to need a fimilar operation; and this fact is mentioned both by the Arabian and Greek phyficians, particularly by Paulus Œgineta, Œtius, Avicenna, Albucafis, &c.

This operation requires but little fkill in the performance, except in guarding againft any accident to the glans, and in taking care to divide the inner as well as the outer fold of the prepuce. The ftate of the difeafed parts may occafion fome diverfity in the mode of circumcifing, but, in general, one of thefe two methods is expedient:

1. *Firft*,

First, to draw forward the prepuce, and hold it between a pair of forceps; then to cut off the projecting portion of skin with one stroke of the scalpel: or, *Secondly*, to introduce a narrow bistory, concealed within a deep director, until it reaches the top of the corona glandis; next, after pushing the bistory through the upper part of the foreskin, and bringing it along to the extremity, cut around the whole prepuce nearly in a circular direction, till the superfluous portion is removed. But in making this latter incision, it is necessary to avoid touching the frænum and glans, lest the patient should suffer unnecessary pain and subsequent injury from the surgeon's carelessness in operating.

The first method of circumcising is not eligible, if it be designed to expose the whole surface of the glans, although we may sometimes be required to take away only a small part of the prepuce, or even to lay it open without removing any. The after-treatment is very simple, provided the parts are not diseased. The softest and least irritating dressings are most proper. The patient should keep in bed, or recline on a couch, for a few days, and shun all causes of inflammation. See PHYMOSIS, WARTS, LUES VENEREA, and SYPHILIS.

CIRCUMCISION is also the name of a feast celebrated on the first of January, in commemoration of the circumcision of our Saviour. This day was anciently kept a fast, in opposition to the Pagan superstitions, who feasted on it in honour of the god Janus.

CIRCUMFERENCE, formed from *circum*, *about*, and *fero*, *I carry*, in *Geometry*, the curve line that incloses a circle, or circular space; called also the periphery.

All lines drawn from the centre of a circle to the circumference, called *radii*, are equal.

Any part of the circumference is called an *arc;* and a right line drawn from one extreme of the arc to the other, a *chord*. See ARC and CHORD.

The circumference of every circle is supposed to be divided into 360 equal parts, which are called *degrees*. See DEGREE.

The angle at the circumference is double that at the centre. See CIRCLE.

The circumferences of circles are to each other as their radii. See CIRCLE.

And, since the circumference of one circle is to its radius, as that of any other circle to its radius; the ratio of the circumference to the radius is the same in all circles. For the method of estimating the proportion of the diameter to the circumference, see DIAMETER, RECTIFICATION, and QUADRATURE.

CIRCUMFERENTOR, a mathematical instrument used by land-surveyors, for taking angles by the magnetic needle. It is an instrument (where great accuracy is not desired) much used in surveying, in and about woodlands, commons, harbours, sea-coasts, in the working of coal mines, &c. &c. where a permanent direction of the needle is of the most material consequence in surveying.

In *Plate* II. of *Surveying*, *fig.* 1. represents the general form of the modern circumferentor. It is made of brass, and, in its most simple state, consists of the following parts. A, a brass compass box, about five inches diameter, or more. On the plate of the box, are engraved and lettered the principal points of the compass, divided into four quarters of 90 degrees each, two of the quarters being figured from the south point, and terminated by 90 degrees at the east and west; and the other two quarters from the north point, terminating also at the east and west. On the circumference of the plate, is fixed a ring, divided into 360 degrees, numbered from 0 to 360; the observer may therefore take his angles, as bearing from the north and south towards the east and west; or, by that which is the most usual method, the whole circumference of a circle of 360 degrees, commencing from the north point. A magnetic needle of the usual kind turns upon an iron point, fixed in the centre of the compass plate. A stop and trigger wire is applied to the compass box, to throw the needle off its centre when not in use, in order to preserve the fineness of the centre point. A glass and brass spring ring covers the needle and closes the box. To the under side of the compass box, at the N. and S. points, is connected the bar B B, about 15 inches long from end to end, to each end of which is fixed a perpendicular brass sight C C, about five inches long, each sight containing a long slit or perforation, and a sight line, so that the observer may take his line of sight, or observation of the line, upon the station mark, at which end of the bar he pleases. A brass socket is fixed at the centre under the compass box, which is fitted to and turns upon the brass ball and socket of the parallel plates D *d*. The under part of the plate D is screwed to the centre of the brass plate of the folding staves E. This screw makes fast the plates D *d* to the staves E, and a similar screw makes fast the socket of the circumferentor above, to the other plate, *d*. The instrument is levelled by turning the 4 screws *a a*, &c. between the plates D D, and kept fast. The instrument in the figure is represented as placed up in the field ready for use; when done with, the sights C C may be taken off the bar B B; the parallel plates by unscrewing the two screws above mentioned, are separated both from the staves and circumferentor, and thus the instrument is packed into a portable case, and the staves folded together in a small space. Improvements applied to this instrument, to render it more portable and increase its uses, will be hereafter mentioned.

To observe an Angle by the Circumferentor.

Suppose the angular distance of two objects, or marks A B, *fig.* 2, be required, as seen by an observer at C. Place the instrument at the station point C, and, looking through the sight at the north point of the compass box, direct the line in the opposite sight to cut the centre of the object at A, by means of the tangent screw *m*. Notice the degree, and part of the degree, that the point of that end of the needle marked south points to, in the divisions of the circle of 360 degrees, which suppose to be $157\frac{1}{2}$ degrees, or 157° 30′, then turn the instrument on its centre, by the screw *m*, till you observe the centre point of the object B, and note the degree pointed to, which suppose to be 199° 40′. Subtracting the preceding less number from this greater, gives 42° 10′, the angle required. In turning from a degree between 180 and 360, to another on the commencement of the graduations, the remainder may exceed 180 degrees, if so that quantity taken from 360 degrees, the remainder will be the just angle. In this manner, any number of the interior angles of a field may be expeditiously taken.

To take the Plot of a Wood, Park, &c. by observing the Bearings of certain Station-lines encompassing that Wood, by the Circumferentor, fig. 3.

The instrument is to be placed at the first convenient station (a), with the north point of the compass turned from you, or, which is the same thing, your eye placed at the sight aperture over the south point. Direct the line of sight to the mark placed at the station b, and note the degree of the circle, that the north point of the needle points to, which suppose to be 260° 30′. Enter this in your field book, as the bearing of the line a b. Measure onward the length of your station line a b, noting the offsets for the irregular boundary. Move the instrument to the station b,

 keeping

keeping the north point of the compass still from you. Observe the mark at the third station c, and the degree that the same end of the needle before used points to, suppose $292^\circ\ 12'$ (the $12'$ being by estimation). This note also in your field book, for the bearing of the line $b\,c$; and in proceeding on to the station c, measure the length of the line $b\,c$, noting the offsets. In this manner the bearings and lengths of the other station lines may be taken.

If the circumferentor is placed at every other station, half the trouble of setting it on the ground will be saved; but in this case the back as well as fore observations of the marks must be taken. Thus, if the instrument had been placed at b, the north point or sight must be towards you, when you look back at the first station (a), and the same point from you, as before, when you look towards the station c, to make the bearings the same as if taken by the preceding method. Yet as the length of all the station lines must be measured with the chain, no trouble relative to them can be avoided; and, in general, it may prove the best way, to set the instrument down at every station, which will afford you the better opportunity of detecting an error in the just direction of the needle, or in observation, as in the following manner. Suppose the instrument fixed at a, the sight directed to b, the north point of the compass from you, and the north point of the needle was observed to point to $260^\circ\ 30'$ the instrument afterwards being moved to b, and the north point of the compass *towards* you, direct the sight back to a; if the north point of the needle point to the same $260^\circ\ 30'$, as before, when at a, there is no error either of needle or observation; but if it do not, the cause of the error must be ascertained. The perfection or correct traversing of the needle is easily discovered by the following observation. When the needle is in a quiescent state, observe the particular degree that one of its ends exactly points to, then with the approach of the blade of a pen-knife, a key, or other piece of iron, attract one of its ends 40 or 50 degrees from its position, leave the needle then to vibrate and settle, and if it rest, pointing precisely to the same degree as before, the error is not that of the needle's imperfection, but either in some extraneous body secretly influencing its direction, or in the observation itself. A blunt centre-point on which the needle turns, imperfect centre-cap of the needle, or iron particles in the cast brass of the compass-box, are causes which sometimes prevent the just action of the needle and constitute a bad circumferentor. The best and most perfect sort of needles have a small polished agate stone fixed in their centre.

In surveying by the circumferentor, the lengths of the offsets from the station lines to the irregular boundaries are to be measured and entered in the field book as usual in the other methods of surveying.

To protract the above-mentioned Survey as taken by the Circumferentor.

Suppose the bearings and lengths to be as follow:

St.	L.	Bearings.		Lengths.
a	b	260°	30	1242
b	c	292	12	1012
c	d	331	45	1050
d	e	59	00	1428
e	f	112	15	645
f	a	151	30	1806

The surveyor must provide himself with a brass protractor about 6 or 7 inches in diameter, either of the circular, or semi-circular form, divided into degrees and half degrees. The circular form is mostly used, as saving time and causing less chance of error, in protracting expeditiously. The order of the numbering of the 360° should be in the contrary way to that of the circumferentor, but most protractors have a double row of figures, commencing in order from the opposite ends of the diameter.

Draw several lines over the intended draught, *fig.* 3, at a distance from each other not greater than the diameter of the protractor, marking their extremities with the letters N. and S. for the north and south points. Consider in which direction the plot will extend. Assign a point in one of the parallel lines to represent the first station a; to which point lay the centre of the protractor with the diametrical or fiducial edge to coincide with that line. Look into the field book for the bearing of the first station-line, $a\,b$, $260^\circ\ 30'$, at that number on the limb of the protractor, make a point or mark, and through that mark from the assigned point a, draw the line $a\,b$, on which line by your plotting scale of equal parts set off $12^{c}\ 42^{lks}$ as noted in the field book; hence will the line $a\,b$ on the paper have a similar bearing to that of the same station-line taken in the field. The offsets are next to be made, and the true boundary of that side of the wood will be given.

If the protractor be a semicircle, it should be numbered first on the outer edge on to 180°, and then on the inner circle, with numbers increasing the same way to 360°. These inner numbers are for bearings greater than 180°, and the 0 of the numbers must be laid northward or southward, as the degrees of bearing are less or more than 180°.

Next lay the centre of the protractor on the point b, with its diameter upon a parallel with the north and south line, and mark off on its limb $292^\circ\ 12'$, through which from b draw the line bc, mark its length 1010^{lks}, or 10 chains 10 links. Set off the offsets, and thus will that side of the wood be determined. Proceed on in the same manner for the other lines $c\,d$, $d\,e$, &c. and the last line $f\,a$ will terminate exactly or very nearly so at the point a, if the observations have been correctly made.

Of the Improved Circumferentor.

From what has been observed, the reader will understand, that by the circumferentor, as originally constructed, the angles can be taken but by the needle only, and which from the uncertainty of the accurate position of the needle, is not sufficient for some surveys where the accuracy of an angle is of great importance. Several years back Mr. Wm. Jones, optician, of Holborn, published a contrivance of an improvement on the circumferentor, whereby it might serve the purpose of a common theodolite, as well as a circumferentor, that is, to take the angles by a moveable nonius turning against the divided circle of degrees, independent of the needle, and like a common theodolite, serving as an occasional check upon the position of the needle. It was rendered useful also as a spirit-level, and to give angles of altitude and depression, with other advantages, as will be seen by the following description. *Fig.* 1 contains the representation of the improvements. The outside brass rim A, of the compass-box, is fixed to a circular plate placed under that of the compass, but moving independent of it, to which the bases of the sights B B are screwed. Within side of the rim, under the glass, is screwed a small brass nonius scale-piece, g, on which is divided a nonius scale adapted to the divisions of the circle of 360°, and subdividing it into 5 or 3 minutes of a degree, as may at first be desired. The centre of this scale is placed exactly in the line of sight. When the instrument is to be used as a circumferentor only, the under moving-plate and the compass-plate

plate are kept together with a brafs pin, and turning upon the ball and focket within the parallel plates D*d* as before defcribed. When the angle is to be taken in degrees and minutes, independent of the needle, as in a theodolite, this pin is taken out, and the fights with the nonius-fcale moved round the compafs-circle in the fame manner as the index limb of a theodolite, and the angle in degrees and minutes read off by this nonius. The directions for taking a furvey by this inftrument are the fame as are given under the article [illegible].

To ufe this inftrument as a level, an opening is cut in the fide of the focket to admit of the pin of the ball, when the compafs box A is turned into a vertical pofition. The [illegible] on of the fight hole is made, by turning the whole [illegible] ent vertically on the centre of the ball, by the fcrews *aa*, &c. till the air bubble of the fpirit level F, fcrewed to and adjufted under the compafs box, reft exactly in the middle. If angles of altitude or depreffion are to be taken, the centre of the compafs is to be fcrewed faft to the ball, then the pin con[illegible] g the two plates being taken out, the fights and no[illegible] may be moved either above or below the horizon[illegible] on, till the object be feen through the little fight [illegible], and the angle in degrees and minutes read off by [illegible] ion of the nonius fcale at the circumference of the [illegible] For a more accurate motion of the plate and index *B B*, the edge of the compafs plate is in fome inftruments cut with teeth, and a pinion, adapted to thefe teeth, is fixed to the under moveable plate, fo, that by turning the pinion, the fights may be carried round to the mark in the moft fteady and accurate manner. To render the inftrument more portable, the fights, with their bafes *B B*, are kept to the plate under the compafs box, when in ufe, by two finger fcrews, one of which is fhewn at G, and when not in ufe, taken away by unfcrewing the fame fcrews, fo as to admit the whole inftrument with its ball and focket without the ftaves, to pack into a cafe but feven inches fquare, and three inches deep.

For a more extenfive application of circumferentors in land-furveying, particularly in a method ufed by Mr. Gale, we refer the reader to Mr. William Jones's edition of the late Mr. George Adams's Geometrical and Graphical Effays, 1803, page 290, *et feq.*

CIRCUMFLEX, in *Grammar*, an accent, ferving to note or diftinguifh a fyllable of an intermediate found between acute and grave; and generally fomewhat long. See Accent.

It is feldom ufed among the moderns, unlefs to fhew the omiffion of a letter which made the fyllable long and open; a thing much more frequent in the French, than among us: they write *pâte*, for *pafte*; *tête* for *tefte*; *fûmes* for *fufmes*, &c. They alfo ufe the circumflex in the participles; fome of their authors write *conneu. peu*; others *connû, pû*, &c. Father Buffier is at a lofs for the reafon of the circumflex on this occafion.

The form of the Greek circumflex was anciently the fame with that of ours, viz. ^; being a compofition of the other two accents ʌ in one.—But the copyifts changed the form of the characters, and introducing the running hand, changed alfo the form of the circumflex accent, and inftead of making a juft angle, rounded it off, adding a dafh, through too much hafte; and thus formed an *s*, laid horizontally, which produced this figure , inftead of this ^.

CIRCUMFLEXA *femoris externa*, and *interna*, in *Angeiology*, two branches of the arteria profunda femoris. See Artery.

Circumflexa *humeri*, *anterior*, and *pofterior*, two branches of the axillary artery. See Artery.

CIRCUMFLEXUS *palati mollis*, one of the mufcles belonging to the foft palate. See Deglutition.

CIRCUMGYRATION, the wheeling motion of any body round a centre.

CIRCUMINCESSION, in *Theology*, a term whereby the fchoolmen ufe to exprefs the exiftence of three divine perfons in one another, in the myftery of the Trinity. See Person.

The fchool divines are not the firft authors of this term: Damafcenus, in the eighth century, having ufed the word περιχώρησις, which fignifies the fame thing, in his explication of that text, *I am in my Father, and my Father is in me.*

CIRCUMLOCUTION, from *circumloquor*, *I fpeak about*, in *Oratory*, denotes a circuit, or compafs of words; ufed either when a proper term for expreffing any fubject naturally and immediately does not occur, or when a perfon wifhes to avoid fomething difagreeable, inconvenient, or improper to be expreffed in direct terms, and conveys the fame fenfe in a kind of paraphrafe, fo formed as to foften or break the force of the fubject.

Thus Cicero, unable to deny that Clodius was flain by Milo, owns it with this circumlocution, "Milo's fervants being prevented from affifting their mafter, who was reported to be killed by Clodius; they, in his abfence, and without his privity, or confent, did what every body would expect from their own fervants on fuch an occafion."

CIRCUM-POLAR *Stars*, are fuch ftars as, being pretty near our north-pole, move round it; and in our latitude, never fet, or go below the horizon.

CIRCUMPOTATIO, in *Antiquity*, a funeral feaft, provided in honour of the dead.

This was very frequent among the ancient Romans, as well as among the Athenians. Solon, at Athens, and the decemviri at Rome, endeavoured to reform this cuftom, thinking it abfurd that mirth and drunkennefs fhould mingle with forrow and grief.

CIRCUMSCRIBED *figure*, in *Geometry*. See Circumscribing.

Circumscribed *hyperbola*, one of the fecond order, according to Sir Ifaac Newton, which cuts its afymptotes, and contains the parts cut off within its own fpace. See Hyperbola.

CIRCUMSCRIBING, in *Geometry*, denotes the defcribing of a polygonous figure about a circle, in fuch manner as that all its fides are tangents to the circumference.

The term is fometimes alfo ufed for the defcribing of the circle about a polygon; fo as that each fide is a chord. But in this cafe, we more ufually fay, the polygon is infcribed, than the circle circumfcribed. See Polygon and Circle.

The fide of a hexagon is equal to the radius of a circumfcribed circle. See Hexagon. For the method of circumfcribing a circle about any given regular polygon: See Polygon. For the method of circumfcribing a fquare or any regular polygon about a circle: See Square and Polygon. See alfo Quadrilateral, Pentagon, Hexagon, Dodecagon, &c.

CIRCUMSPECTE' *agatis*, the title of a ftatute made ann. 13 Edw. I. relating to prohibitions, prefcribing certain cafes to the judges, wherein the king's prohibition lies not.

CIRCUMSTANCES, the incidents of an event, or the particularities that accompany an action.

The circumftances of the actions of men, are expreffed in this Latin verfe:

Quis, quid, ubi, quibus auxiliis, cur, quomodo, quando.

Quis, who, denotes the quality, ftate, age, &c. of the perfon.

fon. *Quid*, what, the greatnefs, fmallnefs, multitude, fewnefs, &c. of the thing. *Ubi*, where, the place. *Quibus auxiliis*, with what affiftances, the inftruments, means, &c. *Cur*, why, on what account, with what view. *Quomodo*, how, the quality of the action, as to intention or remiffnefs, defignednefs or cafualty, fecrecy or opennefs. *Quando*, when, the time; as on a holiday, at the hour of prayer, &c.

CIRCUMSTANTIAL *evidence*, in *Law*, or the *doctrine of prefumption*, takes place next to pofitive proof: circumftances which either neceffarily or ufually attend facts of a particular nature, that cannot be demonftratively evinced, are called prefumptions, and are only to be relied on till the contrary be actually proved. See EVIDENCE and PRESUMPTION.

CIRCUMSTANTIBUS, in *Law*, is ufed for the fupplying, and making up the number of jurors (in cafe any impannelled appear not; or appearing, be challenged by either party), by adding to them fo many of the perfons prefent, or ftanding by, as will ferve the turn. Stat. 35 Hen. VIII. c. 6; and Stat. 5 Eliz. c. 25, for Wales.

CIRCUMVALLATION, in *Fortification*. A line of circumvallation is a work confifting of a ditch and parapet, with redans, or baftions, from diftance to diftance, with their faliant angles towards the country or the field thrown up by the befiegers of a place, againft any attempts of the enemy from without. It differs from a line of contravallation, or countervallation, in this refpect, that the latter is thrown up between the befieger's camp and the place befieged, to prevent any attempts of the befieged from within, and is feldom made quite fo ftrong as the line of circumvallation.

The refolving upon fieges, or the coming to a determination to befiege places, which is an affair of the cabinet, unlefs the general who commands the operating army has fo far the confidence of his fovereign and his minifters, as to be at liberty to act as he thinks, or according to his own difcretion, is the natural confequence of that fuperiority which we fuppofe ourfelves to poffefs over our enemies. But the carrying of them fuccefsfully into execution, if the places be bravely and ably defended, is an undertaking that may juftly be regarded as one of the moft ferious, important, and difficult parts of war, and therefore requires much precaution, preparation, prudence, and circumfpection. Their fuccefs depends on the obfervance of various meafures; of which the following may be confidered as the principal.

1ft. Secrecy, without which it is very difficult to fucceed.

2dly, A fufficient number of forces for attacking your enemy's places, and for defending your own.

3dly. A knowledge of the difpofitions of the enemy. For if they are re-united, and in as great force as yourfelves, they can prevent you from undertaking any fieges.

4thly. That the magazines neareft to the places you mean to inveft, are abundantly fupplied, and in a favourable condition for your purpofe.

5thly, To feize on the moft favourable times and feafons for carrying on your operations; for all times are not proper for fieges, nothing being more ruinous to an army than thofe that are carried on in winter. That feafon ought, therefore, to be avoided as much as poffible.

Laftly, An eftimate and knowledge of the expence that will attend them; for money being the finew of war, no military operations of confequence can be carried on without it.

Thefe are the principal objects of confideration beforehand, and for which the neceffary meafures fhould be taken at leifure. And after all, when we fuppofe them to be well taken, it frequently happens that the whole fails; for the enemy, who feldom or ever takes the fame view of things that we do, may interrupt us, by being, in the firft place, as ftrong as we are, and obferving our motions and proceedings in due feafon; or, fecondly, by forming the defign of undertaking fome enterprife againft places which it is of more confequence to us to preferve, than the conqueft of thofe we intend to attack; or, thirdly, by being in a condition to over-run our country, or part of it, and carry defolation into the fame, whilft we are occupied with the fiege of fome place, the capture of which, that may be doubtful or uncertain, would not by any means compenfate for the lofs we fhould thereby fuftain; or, laftly, by having it in his power to give us battle before we can eftablifh ourfelves before the place we wifh to attack.

All thefe confiderations ought to be well weighed before we undertake the fiege of a place; and the time for the fame fhould be fo judicioufly chofen, that the enemy cannot fall upon us fuddenly, before we eftablifh ourfelves in the enterprife, by fecuring our befieging army with a line of circumvallation, or even countervallation. The beft plan is to have a fuperior force to that of the enemy, and to have two armies when it is practicable, viz. one to befiege the place, and the other to watch and obferve. The befieging army confines itfelf within its lines, whilft the army of obfervation only moves about, keeps a look-out, and occupies the avenues, or approaches, by which the enemy can approach or prefent himfelf; or takes pofts, and there retrenches himfelf; or if the enemy moves to a little diftance, follows him, keeping always in fight of him, but conftantly pofting itfelf between him and the befieging army fo advantageoufly as not to be under the neceffity of fighting, contrary to his wifh or inclination. If we can only gain a few days' time at the commencement of a fiege, it is of very great advantage.

Thefe two armies, viz. the befieging army and the army of obfervation, ought always to keep themfelves within reach of each other, particularly during the commencement of a fiege, in order to be able to fuccour or fupport each other, and keep the enemy at a diftance, who on his part ought to be apprehenfive of approaching too near to the place, for fear the two joining together, if they be ftronger than he is, falling upon him and attacking him with advantage.

The army of obfervation is, befides, of great advantage to that which carries on the fiege, as it watches for its fafety, and favours its operations by efcorting its convoys, furnifhnifhing it with fafcines, and performing other neceffary duties and fervices. And the befieging army can reciprocally, in cafe of need, reinforce the army of obfervation after the firft fix or feven days of opening the trenches, when it has well taken its advantages and precautions againft the place invefted.

It is alfo a very favourable circumftance to be able to attack before the enemy is in a condition to take the field with all his forces, or in the fall, when part of his troops are retired or withdrawn, and he is no longer in fufficient force to oppofe our enterprifes.

To take advantage of the firft of thefe circumftances, it is neceffary to have large magazines of forage within reach of the places you wifh to inveft, and always to have an army of obfervation, if poffible.

We have already obferved, that it is neceffary to have magazines near to and within reach of the places we defign to inveft, and particularly of forage, if we mean to attack them before the enemy can take the field with all his forces. But we have not attempted to mention the number, or defcribe the natures of the different magazines, or the quantity of each fpecies species of stores, they ought to contain. For to ascertain this is difficult, and in attempting to do so one can only be regulated by a reference to the relative degrees of strength, importance, &c. of the places to be attacked. If the place be considerable and of consequence, one should reckon on a siege sufficiently long for one month at least of open trenches. For it rarely happens that a place cannot hold out that time if it be tolerably well garrisoned, and be defended by intelligent officers, who wish to do their duty. A surplus of ammunition and stores at command, occasions no loss or inconvenience, but a deficiency may make the enterprise miscarry.

Besides having from 8 to 900,000 weight of powder, according as the place is more or less strong, there should be from 40 to 60,000 large bullets; from 16 to 20,000 smaller ones; from 12 to 16,000 shells; from 30 to 40,000 grenades; from 8 to 10,000 matches; from 150 to 180,000 weight of lead; 100,000 musquet flints, strong and well chosen; 50,000 sacks of earth; 30.000 small charges of powder ready made up; spare timber for bridges of communication, and other purposes; a sufficient number of horses for the artillery; cannon or guns of various sizes, for the defence of the lines, and other services; mortars for throwing shells and stones; shot, shells, grenades, leaden bullets, matches, flints; platforms complete for guns and mortars; spare carriages for guns; spare beds for mortars; spare sponges, rammers, and ladles; intrenching tools; carpenters' ditto; sling carts and carriages of different descriptions, &c. &c.

When all the necessary preparations are made, and the measures well taken, when the siege of a place is resolved on, and the armies in short are in the field, and in a condition for acting, the general should, by his movements, do his utmost to remove the suspicions which the enemy may entertain of his designs, and to direct them towards other objects as much as he is able. Sometimes this consideration will carry him so far as to invest a place which he has no wish to attack, in order to make the enemy change his notions and measures, and thereby lead him to weaken the garrison of the place he really means to besiege. It was in this manner that the allies, in 1710, appearing to menace Ipres, occasioned the best part of the garrison of Tournay to be withdrawn from it, which being itself invested next morning, was not of consequence in a condition to make the resistance that might have been expected from it, though it was at that time one of the strongest places in the Low Countries. Sometimes they press on the enemy during several days to drive him to a distance from the place intended to be attacked; after which, and when matters are brought to the point desired, the first thing they ought to do is to invest the place, which is commonly done by a detachment of 4 or 5000 cavalry, more or less, according to the strength of the garrison, commanded by a lieutenant-general and two or three major-generals. These troops should march day and night, till they come within a league or two of the place, where halting they regulate their particular arrangement, and the dispositions of the investiture, in such a manner, that they may all of them be able to arrive at the same hour to nearly the distance of cannon shot from the place.

These occupy and command all the avenues favourable for throwing succours into the place, and shut it up as closely as possible, by seizing on posts all around it, pushing on detachments to the very gates to carry off men, cattle, and whatsoever else they can find without the works, that may be serviceable to the garrison. During the day, they keep themselves out of the reach of the cannon of the place; but at night they approach to the distance of about musquet shot from the works, in order to be able to form round it a circle, so furnished with troops, as to leave no, or but small intervals, or empty spaces between them. In this situation they turn their backs on the place, and post small guards both in front and rear of them to prevent surprise. They dispose of themselves, in short, in such a manner, as to be ready to make head against the enemy, on whatever side he may present himself, keeping always half the cavalry appointed to support them mounted, whilst the other half of them is dismounted to give both the men and horses some repose. In the morning they retire by degrees towards the dawn of day, frequently halting as they retire till sun rise, when they return to their quarters or former posts, placing the ordinary guards towards the place and stronger ones in the avenues on the side of succours; after which the squadrons who are not on guard, retire to the camp to repose themselves, without taking off either their own cloaths or the saddles of their horses, but merely for the short time necessary for dressing them, that they may be in readiness to mount at a moment's notice.

During this time he, who commands, sends parties to learn intelligence of the enemy; he continues to make his arrangements, and to reconnoitre the situation the most convenient for placing the camps, and fixing the directions of the lines, as soon as the artillery shall arrive. This is a point to which the engineers, who should be on the spot as soon as the investing detachment, ought particularly to direct their attention. When those, who form the investiture, have some troops of infantry with them, they dispose of them in small guards on the principal avenues of the place, supported by larger ones posted behind them. And when infantry is wanting, they employ dragoons instead of them.

Whilst these dispositions are making, the army makes forced marches, and commonly arrives before the place the second, third, fourth, or at most the fifth day after the investiture. The lieutenant-general, who has formed advances from his troops to the distance of half a league or thereabout, is to meet the general, and render him an account of his diligence, expedition, and preparations; and the general on his report makes his final arrangement for the encampment of the army round the place.

Next morning he rectifies it if necessary, and in company with the other general officers and principal engineers, makes the circuit of the place, reconnoitring the ground for the purpose of finally determining its line of circumvallation. After having agreed on the figure and circuit of the lines, which ought always to regulate the encampment, the general distributes all the troops, according to the quarters destined for them, and assigns to each general officer his own.

The line of circumvallation is the first work of any magnitude, that is thrown up after the investiture of a place, and is intended not only for shutting it up so completely, as to prevent any supplies of men, ammunition, cannon, military stores, or provisions from being thrown into it, but also for securing the camp of the besieging army against insult or attack from without, or from the side of the country. As this line is calculated for protecting the besieging army and its camp against any attemps of the enemy from the field: so the line of countervailation, which is formed in a similar manner, and is made between the camp and the place, when the garrison is strong, is intended for securing it against any attacks from the besieged. The saliant angles of the line of circumvallation look externally towards the country, whereas those of the line of countervallation look inwards towards the place invested.

In tracing both these lines, care should be taken to occupy the

the most advantageous ground in the neighbourhood of the place, without being over scrupulous about its being a little too near to, or a little too far off from the same.

As to the camp of the besieging army, it ought to be placed, or pitched in such a manner, that the rear of it may not be within reach of the cannon-shot of the place. On the other hand, it should not be advanced too far from the same into the field, but ought to occupy precisely, if possible, ground at the distance necessary for its security.

Particular attention ought also to be paid to the avoiding of all eminences or high situations, that may command any part of the camp, and when this is impracticable, to take them within the line, if it should not be thereby rendered too extensive; but if it should, to occupy them with redoubts or other closed outworks.

Advantage should be taken, both in forming and securing this line, of all favourable circumstances, furnished by the nature of the ground and the *environs* of the place; such as precipices, morasses, rivers, rivulets, pools, hedges, lanes, thickets, woods fit for making *abattis*, &c.

The justly celebrated Vauban generally made his lines of circumvallation with *redans*, and ravelins, opposite to the gates or sally ports, taking care to place the said works, for the flanking defences, on the higher parts of the ground, if possible, without minding whether the distance between the saliant angle of one *redan*, and that of the next was the customary length of 120 toises or fathoms, or from 10 to 20, more or less, if the ground required it. The openings or gorges of the *redans* were each of them about 30 toises or fathoms, and the capital or depth of each about 20. The gorges of the ravelins, which covered the gates or sally ports, were commonly each of them about 30 toises or fathoms, and the capital of each about 20. Sometimes bastions were employed as well as redans, particularly at the saliant angles of the line of circumvallation, or at the angles formed by the different directions of its component parts.

That famous general and engineer has given six different profiles for lines of circumvallation, in order to make them suit all sorts of them. These are the following:

First Profile. See Section 1st.

	Ft.	inch.
Width of the ditch at the opening or top,	18	—
Width or breadth of the same at the bottom,	6	—
Its depth,	7	6
Solid content of its excavation in *toises courantes*,	15	—
Solid content in cubic toises,	$2\frac{1}{2}$	—
Thickness of the parapet at top,	8	—
Height of ditto within,	$7\frac{1}{2}$	—
Height of ditto without,	6	—

Second Profile. See Section 2d.

	Ft.	inch.
Width of the ditch at the opening or top,	16	—
Width of the same at the bottom,	5	4
Depth of the same,	7	—
Solid content of its excavation in *toises courantes*,	$12\frac{4}{9}$	—
Solid content in cubic toises,	$2\frac{2}{27}$	—
Thickness of the parapet at top,	7	—
Height of ditto within,	$7\frac{1}{2}$	—
Height of ditto without,	6	—

Third Profile. See Section 3d.

	Ft.	inch.
Width of the ditch at the opening or top,	14	—
Width of the same at the bottom,	4	8
Depth of the same,	6	6
Solid content of its excavation in *toises courantes*,	$10\frac{7}{24}$	—
Solid content in cubic toises	$1\frac{103}{144}$	—
Thickness of the parapet at top,	6	—
Height of ditto within,	$7\frac{1}{2}$	—
Height of ditto without,	6	—

Fourth Profile. See Section 4th.

	Ft.	inch.
Width of the ditch at the opening or top,	12	—
Width of the same at the bottom,	4	—
Depth of the same,	6	—
Solid content of the excavation *par toises courantes*,	8	—
Solid content *par toises cubes*,	$1\frac{1}{3}$	—
Thickness of the parapet at top,	6	—

Vauban considers these profiles as sufficient for all the different sorts of lines, of which one may have occasion to make use. They ought to be regulated according to circumstances and necessity. For instance, if you are resolved to wait the enemy within your lines, they should be made good and substantial, according to the first profile. But if you have taken the resolution of meeting him, you may make them as you think proper. It is, however, always safest to make them good and strong.

The first and second profiles are good, the third and fourth middling, and the fifth and sixth are calculated for the lines of small sieges, where you do not however cease to be under the necessity of taking precautions.

As to lines of countervallation, they are of the same nature, fashion, and form as those of circumvallation, except in this circumstance, that they are not so large or strong. They ought not to be neglected, particularly at the sieges of places, which have strong garrisons, whilst the besieging armies are not very numerous. The circuit of the countervallation should be carried in rear of the camps, at double the distance nearly from the same of the line of circumvallation from the heads or fronts of them. The camps or quarters then of the different parts of a besieging army lie between the lines of circumvallation and countervallation, but about twice as distant from the latter as from the former. The besiegers by the line of countervallation shut up the place as closely and as near to it as they can, without exposing themselves to the fire of its artillery. They should avail themselves of every favourable situation of ground that presents itself. In this line they commonly have passages formed with barriers of the same fashion with that of the line itself. But it is not necessary either to have many of these, or to cover them with outworks.

The depth of the camp is generally about 30 fathoms, and its distance from the line of circumvallation about 120.

 The

The diſtance therefore between the line of circumvallation and that of countervallation is commonly about 390 or 400 fathoms.

It has been generally alleged and ſuppoſed, that if the camp of the beſieging army be about 1200 toiſes or fathoms from the covert-way of the place beſieged, it will be without the reach of cannon-ſhot fired from the ſame. This ſuppoſition however will not always hold good. For guns may be caſt of ſuch calibres as to throw both ſhot and ſhells to a much greater diſtance. Let d then repreſent the greateſt diſtance in fathoms to which the beſieged can throw either a ſhot or ſhell from the covert-way; ſuppoſe the rear of the beſiegers' camp to be 200 fathoms farther from the ſame, its depth to be equal to 30 fathoms, and the diſtance of its front from the line of circumvallation to be 120 fathoms. Then the diſtance from the covert-way to this line will be equal to $\overline{d + 350}$ fathoms. Now if, for the ſake of example, we ſuppoſe the place attacked to be a regular octagon, fortified according to Vauban's firſt method, the diſtance from its centre to the covert-way will be about 250 fathoms, which being added to $\overline{d + 350}$ gives us $\overline{d + 600}$ fathoms for the diſtance from the centre of the place to the line of circumvallation. The circumference correſponding to this radius is nearly equal to $\overline{d + 600} \times \frac{710}{113}$ fathoms. But the perimeter of the line of circumvallation, which is ſometimes made with *redans* and ſometimes with *baſtions*, will exceed this circumference by about one-third, and will of courſe be equal to about $\overline{d + 600} \times \frac{710}{113} + \frac{710}{339}$ or $\overline{d + 600} \times \frac{2840}{339}$ fathoms. See Line of Circumvallation, with camp within it, and figures repreſenting parts of the lines of circumvallation at Philipſbourg and Arras, with their ſections.

As there are no obſervations in this work under the article *Attack* that furniſh any information reſpecting the reconnoiſſance of places attacked, or their ſituations, which are inſeparably connected with the modes of attacking, and the fixing of the lines both of circumvallation and countervallation, it is perhaps the more neceſſary to make ſome here on theſe points. But before we proceed to make them, it will not be improper briefly to obſerve, that the parts of the line of circumvallation moſt expoſed to an attack by the enemy from without, ought to be well palliſaded, and even ſometimes to have outworks or a ſecond ditch, or both, and in thoſe places in front of it, where cavalry can act to advantage, to have *trous-de-loup*, or pits placed chequerwiſe 5 or 6 feet deep, and about 8 feet wide at top, with ſtakes planted in the middle of them, projecting about a foot or fifteen inches above the ſurface of the ground. And it is a maxim, which ought not to be loſt ſight of, when ſome parts of the line are naturally by the circumſtances of ground ſtronger than others, to make the reſt by art as nearly as poſſible equally ſtrong.

As to the *reconnoiſſance* of places, there are few of them at preſent in Europe of which we have not plans, that are even printed. Although ſeveral of theſe are not very exact or correct, ſome information, aſſiſtance, and lights may be drawn from them that are far from being uſeleſs. They ought not therefore to be neglected or unattended to any more than charts of the environs of places.

One finds ſometimes the means of learning ſeveral circumſtances reſpecting the condition and ſituation of places by the peaſantry, or people of the country, particularly by workmen ſomewhat intelligent, as maſons, ſtone-cutters, preparers of ſtones, terrace-makers, undertakers, and contractors. You may alſo contrive to get ſome perſon introduced into a place, who, after remaining in it for ſome time, brings you intelligence of what you wiſh to know.

In addition to all that you can learn in this way, on which much reliance ought not always to be placed, you ſhould add what you can diſcover by yourſelf. You ſhould therefore reconnoitre places and their environs in perſon, or cauſe the reconnoiſſance to be made by people truſty and intelligent, which ought to be done with but little noiſe both by day and by night.

By day you cannot approach very near, unleſs you do ſo almoſt alone, becauſe the advanced guards of the place and the cannon diſturb and moleſt you when you are accompanied by others, and prevent your approaching it.

The beſt method you can adopt is to have ſmall advanced guards behind you, concealed in fences, or in ſome ditch ſupported by others a little farther from you, by means of which you advance alone, or with very few attendants. This practice for the moſt part ſucceeds. Theſe are things, for which every favourable moment or opportunity ought to be ſeized; and the inſpection or examination ſhould be ſeveral times renewed. Such methods however of reconnoitring furniſh no inſtruction or information, but in regard to the mode of commencing and conducting the attacks, the number and ſize of the baſtions, of the cavaliers, ravelins, crown-works, redans, the covert way, &c. which to be informed of, is always to know a good deal. But if there be pits or hollows near the place, or other ſpots of cover and concealment, that can be uſeful for any purpoſe of attack, they ſhould be carefully examined. Theſe, however, as well as the dormant and running waters near the place, are in general but very imperfectly reconnoitred.

The better to diſcover and explore all theſe, you ſhould reconnoitre them by night well attended, in order to be able to approach them and touch them, as the ſaying is, with the ends of your fingers, which is not done without danger, even in the night, when your view of things is not very good or diſtinct. But towards morning, in retiring by little and little, or gradually as the light increaſes and the day advances, you diſcover, what you wiſhed to ſee, in a manner more complete. This is a matter in which nothing ought to be neglected. For great advantages are to be derived from a perfect reconnoiſſance of a place.

Beſides it is not a thing always very eaſy to diſcover the ſtrong and weak parts of a place. For reconnoitre it as much as you chooſe, both day and night, you will not be able to know what is within it, unleſs you learn this from others. Wherefore no channel or means of information ought to be overlooked or neglected.

There is hardly any place that has not its weak and ſtrong parts, unleſs it be of a regular conſtruction, of which the parts of the ſame deſcription are all equal among themſelves, and ſituated in the middle of an open level plain, which affords no advantage to one part more than another. Such is New Briſac. When this is the caſe, you may ſay the place is equally ſtrong and weak throughout. The only conſideration, then, is to determine on the attacks with a view to convenience; that is to ſay, to make them on the ſide moſt within reach of head quarters, the park of artillery, and thoſe places from which you can procure ſupplies of faſcines and gabions, and with which you can have the eaſieſt communications. But as places are ſeldom to be met with that are fortified in this manner, and as they are almoſt always regular in ſome parts, and irregular in others, as to their fortifications being generally compoſed of old and new works,

works, they have almost all of them some defect or advantage, either in point of situation, greater on one side than on another, or with respect to the ground of the environs, which occasions a diversity that requires different observations. To develope this as well as possible, is of consequence, and is a matter entitled to the maturest deliberation.

If the fortification of a place have a side situated upon a rock from 25, 30, 40, 50, 60, or 70 feet high, and if the rock be sound and steep, we may pronounce the place inaccessible on that side. If the foot of this rock is close by a river of smooth or rapid water, it will be still worse. If any side on the level ground borders on a river that is not fordable, that cannot be turned out of its natural course, and is bordered on the side of the place with a good fortification, capable of defending the passage of it, we may say the place cannot be attacked on that side. If the course of this river is accompanied by meadows, low and marshy at all seasons, it must appear still more difficult to be attacked on that side.

If the place is surrounded partly with water, and partly with morasses, but accessible at the same by spots of dry ground that border these morasses; if these accessible avenues are well fortified; if there are works in the morasses which are not approachable, and can see in reverse the attacks making on the firm ground adjoining them, such a situation cannot be favourable or advantageous for the attacks, on account of these inaccessible works, and because it is necessary to be able to embrace what is attacked.

If the place be high, surrounded with low lands and marshes, as is frequently the case in the Low Countries, and is not accessible but by causeways, it ought to be considered.

1st, If it is not possible to dry up the morasses; if they commonly become dry of themselves, during any time of the year, and at what season; in short, if they can be drained and rendered dry.

2dly, If the causeways are straight or winding, enfiladed by the place in whole or in part; of what extent is the part that is not, and at what distance it is from the place; what its width or breadth is, and whether it is possible to traverse it and advance along it with trenches, without being exposed to an *enfilade* from the enemy.

3dly, If it be possible to place batteries below or near it, on some spot or spots higher than the rest of the ground round it, that may furnish a cross fire on those parts of the place that are attacked.

4thly, Whether the causeways be so strongly enfiladed, that there are no considerable crossing or transverse parts, that front the place, sufficiently near to it, and whether there is any part that might furnish a considerable cover against its fire, by raising one part of the thickness of the causeways upon another, and at what distance from the place all this is found.

5thly, If the causeways near to one another, which terminate at the place, meet or join in any particular spot, and if, when occupied by the attacks, they can mutually succour and support one another, by the bearings of cannon firing cross ways, or in reverse, on the works attacked.

6thly, What is the nature of the rampart of the place, and its outworks; if it has covert ways; if the causeways, as they approach these, meet or join; and whether there is any advanced ditch, full of either running or dormant water, that separates them.

From all these considerations one ought to conclude, that a place should never be attacked on a side, where there are so many obstacles and difficulties to be encountered, if there be the least prospect of being able to approach it on some other side, because you are always enfiladed and raked by the cannon, without having it in your power to defend yourself against them, or to render yourself master of them, or to embrace the parts of the place that are attacked.

With regard to works on plain or level ground, it is proper to examine, in the first place, on what sides you can embrace the fronts of the attack, because these are always to be preferred to others.

2dly, The number and quantity of the works to be taken before you can reach the body of the place; their natures, and those of the ground on which they are situated.

3dly, If the place is bastioned and reveted.

4thly, If its fortification is regular, or nearly so.

5thly, If it is covered by a quantity of outworks, of what descriptions they are, and how many.

6thly, If the covert ways are well made, countermined, and pallisaded; if their glacis are steep and uneven, and not commanded by the higher works of the place.

7thly, If there are advanced ditches, and of what nature they are.

8thly, If the ditches are reveted and deep; dry, or full of water; of what depth; if the water is stagnant or running; if there are sluices in them, and what descent the running water has in them from its entering into them to its issuing out of them.

9thly, If they are dry, what is their depth; and whether the sides of them are low and not reveted.

Finally, Attention should be paid to this circumstance, that the worst of all are those that are full of standing water.

Ditches that are dry, deep, and reveted, are good. But the best of all are those that are dry, but may be easily filed at pleasure, with a large body of either running or dormant water; because they can, in the first place, be defended dry, and afterwards be inundated, and have strong currents or torrents excited in them, which will render the passage impracticable. Such are the ditches at Valenciennes, on the side of Quesnoy, which are dry, but can be filled by the garrison at any time, either with standing or running water, without the besiegers having it in their power to hinder them. Such are also the ditches of Landau.

Places which have such ditches, with reservoirs of water that cannot be diverted from them, and which they cannot be prevented from using, are very difficult to be forced when those who defend them know how to make a proper use of their advantage.

Reveted ditches, as soon as they have a depth of 10, 12, 15, 20, or 25 feet, are also very good, because neither mortars nor cannon can much injure these revetements, and the enemy cannot enter them but by descents, that is to say, in defiling one by one, or two by two at most, which is subject to many inconveniences. For the besieged can practise various sallies or sorties, against the besieger's passage, and the lodgments of his miners, which occasion much retardation and loss. Besides, when an attack is made or determined on, it cannot be supported but feebly, as all those employed on it must go through one or two passages, and always by defiling, with much inconvenience.

Care should also be taken to examine if the ditches are cut in a rock, and if the rock is hard and continuous. For, if it is hard and difficult to be worked, the besiegers will be obliged to fill the ditches quite up to the level of the covert way, in order to make their passage, which is a tedious and difficult operation, especially if the ditch is deep. For these manœuvres require much arrangement and time, and the besieged, who so much as seriously think of defending themselves, make the besiegers suffer much by their attempts and contrivances, by turning aside their materials, snatching away their

their fafcines, fetting fire to them, and conftantly annoying them with fallies, and the fire of their cannon, mortars, and mufquetry; againft all which the befiegers are obliged to take every precaution, as a heavy fire from a fhort diftance is very dangerous, and reduces them to the neceffity of filencing it by one ftill greater, well difpofed.

After you are well informed in regard to the nature of the fortifications of the place you wifh to attack, you fhould fee if there are any eminences, cover, hollow way, or inequality of ground, that will favour your approaches, and fave you the trouble of opening part of one end of the trenches; and if there is no commanding fituation, from which you can derive advantage, you fhould examine if the ground through which you muft conduct your approaches is foft and eafily turned up, or if it is hard and mixed with ftones, flints, fhells, and bare rocks, into which you cannot fink a trench at all, or to but a fmall depth at moft.

All thefe differences are confiderable. For if the ground is eafily wrought, it will not be difficult to open good trenches in it, without much rifk and in but little time; whereas if it be mixed with ftones or flints, the opening of them will be much more difficult and dangerous, as cannon fhot fired through or along fuch foil are apt to do much mifchief.

If it is a hard and naked rock, in which you cannot open a trench, you muft lay your account with bringing to the fpot all the earth and other materials, of which you may ftand in need; and you will be obliged to make three-fourths of the trench with fafcines and gabions, and even with bales of hair and wool; which will be attended with much lofs of time and fatigue, without making your approaches proof againft cannon or even mufquet fhot. Such labour and attacks fhould therefore be avoided as much as poffible. See Marfhal Vauban's "Attack and Defence of Places."

CIRCUS, in *Antiquity*, an edifice in ufe among the Romans for the exhibition of chariot races, and other games. The circenfian games appear to have been adopted by the Romans from the Etrufcans in the earlieft ages. Romulus eftablifhed the games at the circus almoft as foon as his power, and the rape of the Sabines, which took place at the firft exhibition of thefe games, probably led him to dedicate them to Confus, the giver of good counfels. The circus at firft was a wooden enclofure, in which the fpectators ftood, a few feats being placed for the moft diftinguifhed perfons. It is faid, that in the earlieft periods of thefe exhibitions, the goals or terms, round which the chariots were obliged to turn, were armed with feveral fwords, prefenting their points towards the horfes, thus increafing the intereft of the conteft by the dangers to which it was expofed. This circumftance has given rife to a fingular etymology, adopted by Caffiodorus and Ifidorus, *ludi circenfes quafi circum enfes*.

The firft permanent circus at Rome was built by Tarquinius Prifcus in the valley Murcia, between the Aventine and the Palatine hills. This edifice which obtained the appellation of *Circus Maximus* from its great fuperiority in fize to thofe of a later date, was for a length of time the only circus in Rome; fome have fuggefted that it derived its name from its being appropriated to the celebration of the greater games; and others feek the origin of the appellation in its having been confecrated to the great gods, *viz.* to Vertumnus, Neptune, Jupiter, Juno, Minerva, and the Dii Penates of Rome. It was enlarged by Julius Cæfar, and rebuilt and richly ornamented by Auguftus. At this period it is defcribed by Dionyfius of Halicarnaffus as furrounded by a portico, and having numerous ftaircafes, fo well diftributed as to avoid any confufion of the fpectators in entering or returning; and he adds, that it was $3\frac{1}{2}$ ftadia in length, and 4 jugera broad; which according to the meafure given by Pliny of the Roman ftadium, 625 feet, will give for the length 2187 Roman feet, or fomewhat more than three Englifh furlongs, and its breadth, allowing for each of the jugera 240 Roman feet, will be 960 feet; and it contained 150,000 perfons. This great magnificence, however, was not fufficient for the fucceffors of Auguftus, fince Tiberius, Caligula, Claudius, and Nero, all made additions to it. In the time of the elder Pliny, the Circus Maximus had been fo much enlarged as to be capable of containing 260,000 fpectators; and Trajan fo much increafed its dimenfions, that an infcription placed over the great gate, of which Dion Caffius has given a tranflation in Greek, expreffed that this emperor had rendered it capable of containing the Roman people. Conftantine alfo added new porticoes, and his fon Conftans ornamented it with the great obelifk, at prefent at the Lateran. Of this fuperb edifice there only remain fome indeterminate veftiges on a level with the ground. Tradition has preferved its remembrance, for at Rome the place is ftill called *Cerchi*, which marks the fite of this enormous pile at prefent occupied by gardens and the cemetery of the Jews.

The other circufes at Rome are the following.—

The *Flaminian* circus, which muft have been a confiderable edifice, as it is fo often mentioned by ancient authors. According to Livy, it was founded by Flaminius, the unfortunate antagonift of Hannibal. Dion Caffius relates that Auguftus exhibited in this circus a chace of crocodiles, in which there were thirty-fix killed. Under ground, and among the ruins of vaft arcades, there is ftill a confiderable ftream of water which fupplied this circus. Its only remains are ruins hid beneath the prefent pavement of the city, which is confiderably raifed in that part; and the church and convent of Santa Caterina de Funari, the two palaces of the Dukes Mattei, and feveral adjacent buildings, are erected on its fite.

The modern Piazzi Navona occupies a great part of the area of the *Agonal* circus, of which the name Navona feems to be a corruption. The curved direction of the houfes fituated at its northern extremity, indicates that they are founded upon the circular end of the circus, oppofite to the carceræ.

The right fide of the great bafilica of the Vatican is placed upon the walls of a circus, which, begun by Caligula and terminated by Nero, was one of the moft remarkable at Rome. To this belonged the fuperb obelifk which at prefent ornaments the place of St. Peter's. This circus muft have been deftroyed as early as the time of Conftantine, fince the former bafilica of St. Peter, founded by him, occupied the fame fituation as the prefent edifice. Its direction may be feen in a print given by Fontana, *Il Tempio Vatic.* page 245, by which it appears that the circus was longer than the modern church with the colonnade.

There was another circus begun, as it is fuppofed, by Nero, in the gardens of his aunt Domitia, and finifhed by Adrian. In fome late excavations confiderable remains were difcovered, with many antique paintings.

Heliogabalus alfo built a circus beyond the Porta maggiore, from which was taken the obelifk at prefent erected in the interior garden of the Vatican.

In the Salluftian gardens there was a very fine circus, which it is faid might be filled with water for the exhibition of naumachiæ.

Very little is known of the circus of Flora on the Quirinal, except that the exhibitions were given by the courtefans of Rome.

Uncertain traces remain of fome other circufes, which

Panvinius has marked in his plan of Rome. But one circus, which is fubject to no doubt, is that which is fituated beyond the Porta Capena, at prefent Porta S. Sebaftiana, and whofe ruins have been, by an uniform tradition, defignated as the circus of Caracalla. Of this, which is the only one that preferves any confiderable traces of its ancient form, we fhall give a detailed defcription in a fubfequent portion of this article.

Befides thefe, there are the traces of three circufes in Spain, at Tarragona, Merida, and Saguntum, now called Murviedro; at Nifmes, at Milan and Antioch, and alfo at Conftantinople the Hippodrome.

Although the circufes were conftructed for the exhibition of chariot races, they were alfo ufed occfionally for various other purpofes; for befides the exercifes of wreftling, pugilifm, and the foot race, which made a part of the ludi circenfes, the magiftrates frequently affembled there, and exercifed thofe public functions, which, on account of the great multitude of the people, could not be held in the temples and bafilicas. The Agnaninians having to affemble a general council, appointed it in their circus, where they declared war againft the Romans. Cicero informs us, that many harangues were pronounced in the Flaminian circus. Plutarch fays that Lucullus exhibited his triumph in this circus; and it was in the fame place that Auguftus pronounced the funeral oration of Drufus. The circufes were alfo a kind of public places which charlatans, diviners, and other people of that clafs frequented.

We fhall now proceed, with the affiftance of figures, to defcribe the general and particular forms of circufes. See *Plate* of architecture, in which is reprefented a ground plan of the circus of Caracalla, the only circus of which the remains are fufficient to fhew the real form and proportions of thefe edifices.

A A A, area of the ftadium or fpace upon which the chariots ran. B B B, the *carceræ*, or ftarting pofts. They were not difpofed in a ftraight line making right angles with the fides of the circus, as they have frequently been reprefented, but upon the arc of a circle of which the centre is at the point *c*; the reafon of this oblique and circular difpofition appears obvioufly to equalize the diftance which each chariot had to run. The carceræ, which were open behind and clofed in front by latticed gates, had only the width neceffary for five horfes abreaft, and the length of a car with the horfes harneffed to it. D D, *agere* or *fpina* round which the chariots raced. This fpine was a folid platform of mafonry of about 20 feet wide and 132 toifes long; it was placed nearly upon the right line which may be called the axis of the circus. E E, the *metæ* or goals; E 1 the firft, E 2, the fecond meta; the firft meta was at a determinate diftance from the carceræ, that is at a little more than half the length of the fpine. F F F, circumference of the circus, upon the width of which were diftributed the feats for the fpectators. G, principal gate of the circus, called alfo the triumphal gate. H H, two lateral gates which feparate the fides of the circus from the carceræ. I, gate between the carceræ fomewhat wider than thefe, but of the fame height. K, *porta libitinaria* or *fandapilaria*, a gate for the purpofe of carrying out the bodies of thofe who died in the area. L L, towers at the extremities of the carceræ.

Some of the circufes at Rome were furrounded exteriorly with vaft porticoes, except on the fide where the carceræ were placed; others were merely enlofed with a wall having doors and windows, as is the cafe with the circus of Caracalla. The porticoes not being neceffary for the ufes of the circus, were only added to give magnificence to the exterior, or to ferve as a place of retreat to the fpectators in bad weather. The lower part of the circumference of the circus beneath the feats, together with the porticoes, formed long galleries of arcades or *fornices*, ferving in part for an accefs to the ftaircafes leading to the feats, and in part for the fhops of various traders, among whom were particularly reckoned the courtefans.

The diftribution and difpofition of the interior ftaircafes depended upon the will of the architect; thofe of the circus of Caracalla are very ingenioufly difpofed. The principal ftaircafes led to a number of little doors in the *podium*, which was a long open platform or paffage, leading quite round the edifice, at an elevation of fome feet from the area of the circus. The podium was confidered as the place of honour, into which only the principal magiftrates, the pontiffs, veftals, and perfons of the imperial family, entered. It feems that the feats on the podium were not permanent, fince it was the privilege of thofe who had places there to fend their magifterial chairs. Behind the podium there was a low wall or precinction, in which were diftributed the little doors before mentioned. The feats rofe above one another their whole height, in the manner of the fteps of a ftaircafe; they were fupported on the inclined vault of the gallery or portico beneath them, and afcended from the podium to the top of the external wall. The feats of the circus of Caracalla are to the number of ten, and it is calculated that they might contain about 18,000 fpectators; thus it can only be reckoned one of the fmaller or private circufes.

The great circufes as well as the theatres and amphitheatres were divided into feveral ranges of feats for the purpofe of placing the fpectators according to their condition. The feats began from the wall at the back of the podium, and after fetting off a number fufficient to place perfons of the firft rank, the ftaircafe of feats was interrupted by the omiffion of two or three; this interruption produced neceffarily a platform or ambulatory altogether fimilar to the podium, in which thofe fpectators remained, who, coming too late to the exhibition, found the feats occupied; behind the paffage was erected a wall or precinction from which the feats recommenced. The ambulatory was called *via*, and, according to Vitruvius, its width was to be equal to the height of the precinction. The ranks of feats were called *mœniana*, and of courfe there were as many precinctions and ambulatories as ranks of feats. Separate ftaircafes led to each via through doors in the precinction, which entrances were called *vomitoria*. As the fpectators entered by thefe paffages at the top of the ranges of feats, they would have to defcend to occupy the firft rows of each mœniana, but the feats themfelves were too high to ferve as fteps for this purpofe; accordingly there were ftaircafes provided, called *fcalares*, formed by cutting down a feat into two fteps, thus giving to the ftep half the height and width of a feat. Thefe fcalares were placed exactly oppofite the vomitoria, and beginning from the via, defcended to the lower feat of each range, which was thus divided into a number of compartments called *cunei* in the theatres and amphitheatres, as from the curved form of thefe buildings the compartments of feats were longer above than below, and thus acquired a wedge fhape. In the circufes, the fides being ftraight, thefe divifions were rectangular, but from cuftom were called cunei.

Above the feats there was generally a portico or covered gallery for the lower clafs of people.

To maintain order in fuch a concourfe of people as attended the exhibition, there were perfons called defignators, who were to affign to every one his place that there might be no mixture of perfons of different ranks, a point in which

which Roman pride was very jealous. Tarquin divided his circus into thirty compartments, a number equal to that of the curiæ, into which the people of Rome were at that time divided.

All the feats were covered with wood, which circumftance accounts for the fires which are mentioned to have happened in thefe edifices. It was alfo cuftomary for women to bring cufhions, and ftools to place their feet upon. The boards which covered the feats were divided by fillets into places for one perfon.

It remains to mention the place of the emperor and the imperial family; this was called the *pulvinar*, and appears to have been a magnificent open loggia. The fituation of the pulvinar is not known, but it feems probable that it was placed between the carceræ and the firft metæ, whence the emperor might give the fignal for the ftarting of the cars, and obferve the beginning and termination of the race. Auguftus, in a letter to Livia, fays that he does not wifh Claudius, young at that time, to go to the pulvinar to fee the games, as he was too much in the fight of the people. This prince having fhewn figns of ftupidity from his earlieft years, Auguftus did not like that he fhould be fo foon known to the people. Trajan took away the pulvinar from the Circus Maximus, and Pliny praifes him for having thus, by a rare clemency, familiarized himfelf with the people.

The extremity of the circus oppofite to the femicircular end was called the *oppidum;* this confifted of a feries of thirteen arcades contiguous to one another, but without communication. At each extremity there was placed a tower which rofe confiderably above the reft of the edifice. The arch in the middle, wider than the others, but of the fame height, ferved as an entrance to the circus. This combination of arches and towers, feen at a diftance, gave the idea of a caftle, from which circumftance it derived the name of oppidum. The twelve remaining arcades were the carceræ, whence the chariots begun the race. The divifions of the arcades on the interior front were ornamented with hermas fupporting a cornice in the manner of caryatides; the carceræ were clofed with grated doors to the height of the fpringing of the arch, and the femicircular opening above was filled with a marble lattice. Two of thefe lattices, very elegantly ornamented, are at prefent in the fecond court of the palace Mattei, which is founded upon a part of the Flaminian circus. Each carcera was diftinguifhed by a number, and as fome were lefs advantageous than others, the place of the cars was determined by lot. Diocles, a celebrated charioteer, voluntarily took the worft place during 24 years, to difplay his fuperior fkill. The top of the carceræ formed a terrace, upon which was placed the tribune of the conful. It is not known what was the purpofe of the towers of the oppidum. Bianconi fuppofed that in the upper part was placed a band of mufic, while the lower might ferve to receive machinery for opening the doors of the carceræ.

The *fpina* was the moft refpectable part of the circus, or, in fact, the fanctuary, fince it was dedicated to the gods; this was a bank or platform, nearly $\frac{2}{3}$ of the length of the circus, which, running down the middle of the arena, divided it into two nearly equal parts, thus refembling the fpine of a fifh; upon the fpina were placed a great variety of objects which we fhall proceed to defcribe as nearly as poffible.

At the two extremities of the fpina were placed the metæ or goals, which confifted of three cones placed in a triangle. They were at firft made of wood, but afterwards of marble, and even gilded. On the fummit of each was placed a large egg in memorial of the eggs of Caftor and Pollux. The metæ refted upon the vault of a femicircular temple or chapel, a little wider than the fpina; the circular part of thefe little chapels was at the firft goal turned towards the carceræ, and at the fecond towards the triumphal gate, and their entrances were placed in paffages between them and the fpina. The firft of thefe temples, according to Tertullian, was dedicated to the goddefs Murcia; the altar of the god Confus, who is faid to be the fame as the equeftrian Neptune, was alfo placed here. The long extent of the fpina was ornamented with columns, ftatues, and altars. The fun was the deity to whom it appears the circufes were principally dedicated; this great luminary had a temple on the middle of the fpine, but after the conqueft of Egypt, Auguftus having tranfported feveral obelifks to Rome, this circumftance gave rife to the idea of placing an obelifk upon the fpine in honour of the fun, inftead of the former temple, which became a univerfal practice. One of the many obelifks at Rome bears this infcription on its bafe, "AEGYPTO IN POTESTATEM POPULI ROMANI REDACTA SOLI DONUM DEDIT." The emperor Conftans brought from Egypt the largeft obelifk at Rome, which he caufed to be erected in the Circus Maximus, near to that placed by Auguftus.

According to fome baffo relievos and medals, the ftatue of the goddefs Ifis or Cybele feated on a lion, was placed on the fpina near the obelifk; there were alfo many columns, on fome of which were placed little ftatues of the gods to which they were dedicated. The columnæ meffiæ, feffiæ, and tutelinæ, were among the number, and one column fupported a ftatue of Victory. Before the columns were placed altars, among which Tertullian diftinguifhes thofe dedicated to the three gods of Samothrace, who were called great, powerful, and valiant. There were alfo columns fupporting an architrave, on which were placed feven dolphins, probably of wood, dedicated to Neptune. Thefe were moveable, and ferved to mark the number of turns which the chariots made round the metæ; on another architrave were placed eggs, which probably ferved a fimilar purpofe.

It ought to be remarked, that the fpina was fituated not exactly in the middle of the arena, nor parallel to the fides of the circus, but in an inclined direction, fo that the courfe was wider on the right fide of the circus where it began than on the left, and was gradually diminifhed all the way. The reafon of this deviation appears to be, that the chariots ftarting altogether, required more room in the firft courfe than when they came in feparated by the conteft.

The area of the circus was of earth, but probably beaten. Caligula and Nero carried their extravagant luxury fo far as to cover the area with chryfocolla and minium difpofed in regular figures.

In feveral of the circufes the arena was furrounded at the foot of the podium with a canal called *euripus;* this was 10 feet in width and the fame depth. The euripus feems to have been intended for the defence of the fpectators in thofe cafes where the podium was not fufficiently elevated; it does not, however, appear to have been abfolutely neceffary, fince Nero had it covered over to enlarge the area of the Circus Maximus. On one occafion, it is faid, that Heliogabalus filled the euripus with wine. There is no euripus in the circus of Caracalla.

After the defcription of the circufes, that of the games exhibited in them will naturally find a place. Thefe games were celebrated regularly on certain fixed days, and were named from various deities, as Apollo, Flora, Ceres, Saturn, Confus, Bacchus, &c. They were more or lefs magnificent, according to the ritual; fome were celebrated only once in a century, and were therefore called fecular. Some were inftitut-

ed

ed for the birth-day of the emperor; others for every lustrum, which were called *vota quinquennalia*; and others for ten years, or *decennalia*. The games sometimes lasted several days. There were public funds appropriated to defray the expence, but they were frequently given by individuals who aspired to popular favour. In the lower ages the consuls and principal members of the imperial family generally gave the games and often at a ruinous expence. There is in Gruterus an inscription, in which we read that Aponia Montana, priestess of the god Augustus, gives the Circensian games *ob honorem sacerdotii*, and in another inscription L. Lucretius Fulvianus gives the games *ob honorem pontificatus*.

The games of the circus, which some call "Circensian Games," were combats celebrated in the circus, in honour of Consus, the god of councils; and thence also called "Consualia."

They are also called Roman games, "Ludi Romani," either on account of their antiquity, as being coëval with the Roman people, or because established by the Romans: and the games held there, the great games, *ludi magni*, because celebrated with more expence and magnificence than others; and because held in honour of the great god Neptune, who was their Consus. Those who say they were instituted in honour of the sun, confound the *pompa circensis*, or procession of the circus, with the games. The games of the circus were instituted by Evander, and re-established by Romulus: the pomp, or procession, was only a part of the games, making the prelude thereof, and consisting of a simple cavalcade of chariots.

Till the time of the elder Tarquin, they were held on an island of the Tiber, and were called Roman games: after that prince had built the circus, they took their name therefrom, as being constantly held there.

There were six kinds of exercises in the circus: the first was wrestling, and fighting with swords, with staves, and with pikes; the second was racing; the third saltatio, dancing; the fourth, disci, quoits, arrows, and cestus; all which were on foot: the fifth was horse-coursing; the sixth, courses of chariots, whether with two horses or with four.

In this last exercise, the combatants were at first divided into two squadrons or quadrils; then into four; each bearing the names of the colours they wore; and they were denominated *albati*, *russati*, *prasini*, and *venati*. At first there were only white and red; then green was added, and blue. Domitian added two more colours, but they did not continue. It was Oenomaus who first invented this method of distinguishing the quadrils by colours. These four factions soon acquired a legal establishment: and their fanciful colours were derived from the various appearances of nature in the four seasons of the year; the red dog-star of summer, the snows of winter, the deep shades of autumn, and the cheerful verdure of the spring. Another interpretation preferred the elements to the seasons, and the struggle of the green and blue was supposed to represent the conflict of the earth and sea. Their respective victories announced either a plentiful harvest, or a prosperous navigation; and the hostility of the husbandmen and mariners was somewhat less absurd than the blind ardour of the Roman people, who devoted their lives and fortunes to the colour which they had espoused. Such folly was disdained, and yet indulged by the wisest princes; but the names of Caligula, Nero, Vitellius, Verus, Commodus, Caracalla, Elagabalus, were enrolled in the blue or green factions of the circus. The follies of ancient Rome were adopted by Constantinople; and the same factions which had agitated the circus, raged with redoubled fury in the hippodrome. Whilst a secret attachment to the family or sect of Anastasius was imparted to the greens; the blues were zealously devoted to the cause of orthodoxy and Justinian.

The great Circensian games consisted of a solemn procession, called *pompa*, which was terminated by various sacrifices upon the spina, and a course of a hundred chariots for the diversion of the public.

The exhibition began by the pompa, which descended from the capitol, and, crossing the Forum Romanum, proceeded towards the Circus Maximus, through the street called *Velabrum*; during this time it was unlawful for any person to appear at the windows of the houses. The procession being arrived at the circus, which was already filled with spectators, entered by the great gate; first went the magistrates in their solemn costume, they were followed by a company of children of senatorial and equestrian families divided into centuries, and marching in the same order that they observed in their palestric exercises. After these a hundred aurigæ displayed their cars with two or four horses each car, being accompanied by a light horseman. Wrestlers and athletæ followed, together with dancers and players on musical instruments, who performed pyrrhic and satyric dances. Then came another musical choir, with those who carried the incensers, and other instruments of sacrifice, when the flamens imposed silence in their usual form, *favete linguis*, *favete animis*, upon which it was only permitted to applaud by clapping hands, as the statues of the divinities were carried by. The first deity that appeared was Victory, to whom the Romans were so much indebted; then followed Neptune, to whom the games of the circus were particularly dedicated, and Mars, the father of Romulus and Remus; the Sun and Moon, Minerva, Ceres and Bacchus, Castor and Pollux, Venus and Cupid, with many others followed. In later ages, the statues of deified emperors and their wives were introduced into the circensian pomp. The procession was terminated by the victims destined for the sacrifices, preceded and followed by the pontiffs, priests, augurs, aruspices, flamens, and other ministers of religion: then the sacrifices being performed with all the necessary ceremonies, the persons composing the procession took their places on the seats of the circus, and every thing was prepared for the races.

Each exhibition consisted of twenty-five courses, and each course of four chariots; thus the whole number of chariots required was one hundred; these were divided into four factions, which were distinguished by different colours, white, red, green, and blue. For each course there were drawn by lot the names of four charioteers, one of each colour, together with the number of the carceræ assigned to each, that there might not be any complaint of partiality.

The chariots had at first only two horses, and were called *bigæ*. In process of time there was added another horse, which was called *funarius*, because he was attached to the car by a rope; at length one more horse was added, and the car became a *quadriga*, which was the most general practice. But sometimes the directors of the games added to each car a fifth horse, with a rider; and in the inscription relating to Diocles, there are even mentioned six and seven horses abreast. Such races must have been personal challenges between the most distinguished charioteers, for the regular courses were performed with four horses.

The light cars used in the Circensian games had two wheels, and were nearly balanced upon the axle; the front, which was circular, had a kind of parapet, about the height of the drive-knee: this parapet was gradually diminished

nished on the sides, till it ended in a point, and the back of the car was left open; thus the charioteer mounted behind, and stood upon the floor of the chariot.
